So that this amounts to nothing else than this: two triangles, or any two similar and similarly situated figures, have the duplicate of the ratio of two corresponding sides — that is, triangle is to triangle, or figure to figure, as the first line is to the third, when three lines are continually proportional in the ratio of the two corresponding sides. Such here are the three straight lines BC, EF, BG, continually proportional in the ratio of the corresponding sides BC, EF.

Diagram. Two similar triangles, with a separate line-segment below.

- A (apex of first triangle)
- B (foot, left) — C (foot, right): base BC
- D (apex of second triangle)
- E (foot, left) — F (foot, right): base EF
- B — G (a separate horizontal segment beneath the triangles): the third proportional BG laid out on the line B...G

First, then, let the sides BC, EF be equal, and consequently let the third proportional BG be equal to them, so that the ratio of BC to BG — which is called the duplicate of the ratio of the side BC to the side EF — is a ratio of equality. Now since the triangles ABC, DEF likewise have a ratio of equality [Margin: a. *Elements* I.26], because they are equal to one another (their angles B, C being equal to the angles E, F, and the sides BC, EF, which lie between those angles, being equal), the triangle will be to the triangle as the straight line BC is to the straight line BG. Since, then, this ratio is called the duplicate of the ratio of the corresponding sides BC, EF, the ratio of triangle ABC to triangle DEF will also be called the duplicate of the ratio which the side BC has to the side EF.

This can also be established as follows. Since, as has been said, the triangles ABC, DEF are equal — that is, have a ratio of equality — just as the corresponding sides BC, EF also do; and since a duplicated ratio of equality produces only a ratio of equality (for, three equal magnitudes being set out, the first is said to have to the third the duplicate of the ratio which the first has to the second, as is clear from Definition 10 of Book 5, even though the first has to the third a ratio of equality, just as the first has to the second): the triangle ABC will have to the triangle DEF

the duplicate of the ratio which the side BC has to the side EF. Which was the thing proposed.

Diagram. Two triangles for the case where BC exceeds EF, the larger triangle having its base cut at G.

- A (apex of larger triangle)
- B (foot, left) — G (point on the base) — C (foot, right): base BC with G between B and C, so that BG is the third proportional; AG is joined
- D (apex of smaller triangle)
- E (foot, left) — F (foot, right): base EF

[Margin: b. *Elements* VI.11] [Margin: c. *Elements* V.11] [Margin: d. *Elements* VI.15]
[Margin: e. *Elements* V.7] [Margin: f. *Elements* VI.1]

Next, let the side BC be greater than the side EF; and from BC let there be cut off [Margin: b. *Elements* VI.11] BG, a third proportional to the straight lines BC, EF, and let AG be joined. Now since AB is to BC as DE is to EF, then, by alternation, AB is to DE as BC is to EF. But as BC is to EF, so, by construction, is EF to BG. Therefore [Margin: c. *Elements* V.11] AB is to DE as EF is to BG. Since, then, the triangles ABG, DEF have the sides about the equal angles B, E reciprocally proportional, they will be equal to one another [Margin: d. *Elements* VI.15]; and therefore, as triangle ABC is to triangle DEF, so [Margin: e. *Elements* V.7] will the same triangle ABC be to triangle ABG. But as triangle ABC is to triangle ABG — being of the same altitude — so [Margin: f. *Elements* VI.1] is the base BC to the base BG. Therefore, as triangle ABC is to triangle DEF, so is BC to BG. And since the three lines BC, EF, BG are continually proportional, the ratio of the first, BC, to the third, BG, is called the duplicate of the ratio of BC, the first, to EF, the second. Therefore the triangle ABC also has to the triangle DEF the duplicate of the ratio of the side BC to the side EF. Therefore similar triangles are to one another [in the duplicate ratio of their corresponding sides], and so on. Which was to be demonstrated.

COROLLARIVM

From this it is manifest that, if three straight lines be proportional, then as the first is to the third, so is the triangle described upon the first to the triangle similarly and similarly-situatedly described upon the second.

For let there be three proportional straight lines A, B, C; and upon the first, A, and the second, B, let there be constructed similar triangles A and B, similarly described. I say that, as the straight line A, the first, is to the straight line C, the

third, so is the triangle A to the triangle B. For the ratio of the straight line A to the straight line C is, by definition, the duplicate of the ratio of the straight line A to the straight line B [Margin: g. *Elements* VI.19]. Since, then, the triangle A also has to the triangle B the duplicate of the ratio of the straight line A to the straight line B, it follows that as the straight line A is to the straight line C, so is the triangle A to the triangle B.

Diagram. Two similar right triangles with a short line-segment.

- A (the larger right triangle, right angle at its lower left)
- B (the smaller right triangle, right angle at its lower left)
- C (a short horizontal segment to the right): the third proportional line

In the same way you will show that the triangle upon the second is to the triangle similarly described upon the third as the first line is to the third. For let the three proportionals be C, B, A, and upon B, the second, and A, the third, let there be constructed similar and similarly-situated triangles B and A. I say that, as the straight line C is to the straight line A — [which ratio is] the duplicate of the ratio of C to B, that is, of the straight line B to the straight line A [Margin: h. *Elements* VI.19] — so is the triangle B to the triangle A. Since, then, the triangle B also has to the triangle A the duplicate of the ratio of the straight line B to the straight line A (because B and A are the corresponding sides): as the straight line C is to the straight line A, so will the triangle B be to the triangle A.

SCHOLIVM (to Prop. 19)

And so, if the ratio of the side BC to the side EF is known in numbers — say, as 6 to 5 — we shall also learn from this Proposition 19, in numbers, what ratio the triangle ABC has to the triangle DEF. For if the ratio 6 to 5 be continued in three numbers, thus: 36, 30, 25, the triangle will be to the triangle as 36 to 25 — that is, it will have a ratio whose denominator [multiplier] is $1\frac{11}{25}$. For since the ratio 36 to 25 is the duplicate of the ratio 36 to 30 (or 6 to 5), which the corresponding sides are supposed to have; and since the triangles too have the duplicate of the ratio of the corresponding sides, as has been shown in this theorem: the triangle will be to the triangle as 36 to 25.

We shall find the same ratio of the triangles if we multiply into itself the denominator of the ratio of the corresponding sides — namely $1\frac{1}{5}$. For the resulting number $36/25$, that is, $1\frac{11}{25}$, will be the denominator of the ratio which is the duplicate of the ratio of the sides, and consequently also the

denominator of the ratio of the triangles, since this too is the duplicate of the same ratio of the sides.

So too, if the corresponding sides had the ratio of 10 to 1, the triangles would have the ratio of 100 to 1, since the latter is the duplicate of the former, as appears here: 100, 10, 1. Or again, because the denominator of the tenfold ratio — that is, 10 — multiplied into itself begets 100, the denominator of the ratio which is the duplicate of the tenfold ratio.

THEOR. 14. PROPOS. 20.

[Margin: xviiij.]

Similar polygons are divided into similar triangles, equal in number and corresponding to the wholes; and the polygons have to one another the duplicate of the ratio which a corresponding side has to a corresponding side.

Clavius's demonstration. Let ABCDE, FGHIK be similar polygons, having the angles BAE, GFK equal, likewise the angles B, G, and so on in order; and let the sides about the equal angles be proportional — so that as AB is to BC, so is FG to GH; and as BC is to CD, so is GH to HI, and so forth. I say first that these polygons are divided into similar triangles, equal in number. For from the angles BAE, GFK let straight lines be drawn to the several opposite angles, namely AC, AD and FH, FI; and the polygons will be divided into triangles equal in number.

Now since the angle B is equal to the angle G by hypothesis, and the sides about them are proportional, the triangles ABC, FGH will be equiangular [Margin: a. *Elements* VI.6], having the angles BAC, GFH equal, and likewise the angles ACB, FHG, which lie opposite the corresponding sides. Therefore [Margin: b. *Elements* VI.4] they will have the sides about the equal angles proportional, and consequently they will be similar to one another. By the same reasoning the triangles AED, FKI will be similar, having the angles EAD, KFI equal, and the angles ADE, FIK equal.

Diagram. Two similar pentagons, each divided into three triangles by diagonals drawn from an apex.

- Pentagon ABCDE: A (apex, top), B (upper left), E (upper right), C (lower left), D (lower right); diagonals AC, AD
- Pentagon FGHIK: F (apex, top), G (upper left), K (upper right), H (lower left), I (lower right); diagonals FH, FI

[Margin: c. *Elements* VI.4] [Margin: d. *Elements* V.22] [Margin: e. *Elements* VI.6]

Next [Margin: c. *Elements* VI.4], since AC is to CB as FH is to HG, on account of the similarity of the triangles ABC, FGH; and since CB is to CD, by hypothesis, as HG is to HI, on account of the similarity of the polygons: it follows [Margin: d. *Elements* V.22], *ex aequali*, that as AC is to CD, so is FH to HI. And since the angle BCD is supposed equal to the angle GHI, while the angle ACB, subtracted, has been shown equal to the subtracted angle FHG, the remaining angle ACD will also be equal to the remaining angle FHI. Therefore [Margin: e. *Elements* VI.6] the triangles ACD, FHI, since they have the sides about the equal angles ACD, FHI proportional, will be equiangular, and therefore similar. And the same reasoning holds of all the other triangles, if there be more of them.

I say, moreover, that these triangles correspond to the whole polygons — that is, that any triangle in the one polygon is to its corresponding triangle in the other polygon as polygon is to polygon. For since the triangles ABC, FGH are similar, their ratio will be the duplicate of the ratio of the corresponding sides AC, FH. And by the same argument the ratio of the triangles ACD, FHI will be the duplicate of the ratio of the same corresponding sides AC, FH. Therefore, as triangle ABC is to triangle FGH, so will triangle ACD be to triangle FHI, since each of these ratios of triangles is the duplicate of the same ratio of the side AC to the side FH. And by a like reasoning it will be concluded that triangle ADE is to triangle FIK as ACD is to FHI; and so on in turn, if there be more triangles. The triangles of the one polygon are therefore proportional with the triangles of the other, so that the triangles of the one are the antecedents, and the triangles of the other the consequents, of the proportions. But as one antecedent is to one consequent, so [Margin: f. *Elements* V.12] are all the antecedents to all the consequents. Therefore, as any triangle of the one polygon is to its corresponding triangle of the other, so will the whole polygon be to the whole polygon; and therefore the corresponding triangles are to the whole polygons.

Lastly, I say that the polygons have to one another the duplicate of the ratio which the corresponding sides have — that is, if to the corresponding sides, say AB, FG, a third proportional line be found, then the polygon ABCDE is to the polygon FGHIK as the first line AB is to the third line found. And consequently, since the ratio

of AB to that third line is called the duplicate of the ratio of AB to FG, the ratio of polygon to polygon is likewise said to be the duplicate of the ratio of the corresponding sides AB, FG. For since triangle ABC is to triangle FGH as polygon ABCDE is to polygon FGHIK; and since triangle ABC has to triangle FGH [Margin:

g. *Elements* VI.19] the duplicate of the ratio which the corresponding sides AB, FG have — that is, the same ratio which AB has to that third line found — the polygons too will have to one another the duplicate of the ratio of the same corresponding sides AB, FG, that is, the same ratio which AB has to that third line found. And so similar polygons are divided into similar triangles, and so on. Which was to be demonstrated.

COROLLARIVM

From this it is manifest that, if there be three proportional straight lines, then as the first is to the third, so is the polygon described upon the first to the polygon similarly and similarly-situatedly described upon the second; or again, as the polygon described upon the second is to the polygon similarly and similarly-situatedly described upon the third.

This will be demonstrated from the present theorem in no other way than the corollary of the preceding theorem was shown from its theorem — as is plain in the figure here set alongside.

Diagram. Two squares of unequal size, with a short line-segment, illustrating the corollary.

- A (the larger square)
- B (the smaller square)
- C (a short horizontal segment to the right): the third proportional line

SCHOLIVM (to Prop. 20)

When similar polygons are pentagons, as in the figure, it may also be demonstrated in this way that the middle triangles ACD, FHI are similar. Since the angles ACB, FHG are equal, on account of the similarity of the triangles ABC, FGH; if they be taken away from the angles BCD, GHI, which are likewise equal, on account of the similarity of the polygons: the remaining angles ACD, FHI will also be equal. And by the same reasoning the angles ADC, FIH will be shown equal [Margin: h. *Elements* I.32]; and therefore the remaining angles CAD, HFI will be equal as well. Since, then, the triangles ACD [printed ACC], FHI are equiangular, they will have the sides about the equal angles proportional [Margin: i. *Elements* VI.4], and consequently they will be similar.

[Margin: k. *Elements* VI.6]

But when the polygons have more angles, it must be demonstrated that the middle triangles are similar by way of equality of ratios and by Prop. 6 of this

book, as was done in the proposition — because the angles cannot be proved equal, except for one only, namely the one that lies next to the preceding similar triangle, such as the angle ACD and FHI. For the angle ADC cannot be shown equal to the angle FIH, since in that case there still remain further triangles down to the similar triangles AED, FKI, and so on. I have said this so that no one may suppose we spoke to no purpose in the proposition when we said that AC is to CB as FH is to HG, and CB is to CD as HG is to HI, and consequently, by equality of ratios, AC is to CD as FH is to HI; and therefore, the angles ACD, FHI being equal, the triangles ACD, FHI are similar. For this demonstration is altogether necessary, and fits all polygons of however many angles, since all the middle triangles are shown to be similar in this manner, as is evident. For if the triangles ADE, FIK were not the last, they would be demonstrated similar in this way: since AD is to DC as FI is to IH, on account of the similarity of the triangles ACD, FHI; and likewise DC is to DE as IH is to IK, on account of the similarity of the polygons: it follows, *ex aequali*, that AD is to DE as FI is to IK. And since the angle CDE is supposed equal to the angle HIK, while the subtracted angle ADC has been shown equal to the subtracted angle FIH: the remaining angle ADE will also be equal to the remaining angle FIK. Therefore [Margin: k. *Elements* VI.6] the triangles ADE, FIK will be similar, since they have the sides about the equal angles ADE, FIK proportional. And so on in turn, if there be more triangles.

But if the similar polygons are equilateral and equiangular, they too will be divided into similar triangles, equal in number and corresponding to the wholes, when from the centres of the circles that circumscribe them straight lines are drawn to all the angles. For let ABCDEF, GHIKLM be similar, equilateral, and equiangular polygons, circumscribed by circles about the centres N, O, from which let the straight lines NA, NB, and so on be drawn. I say that the triangles NCD, OIK are similar and correspond to the whole polygons. For the angles CND, IOK are equal (because they are equally submultiples of four right angles: for each of the spaces about N and O, being equivalent to four right angles, is divided — by the corollary 2 of Prop. 15 of Book 1 — into angles equal both in number and in magnitude. For since the angles at the centre N stand upon equal arcs [Margin: l. *Elements* III.27], they will be equal to one another; and by the same reasoning the angles at the centre O will be equal). And the sides about them are proportional, since in each case there is a ratio of equality [Margin: m. *Elements* VI.6]. Therefore the triangles NCD, OIK will be similar. And the same reasoning holds of the rest. But that these triangles correspond to the whole polygons will be demonstrated with no trouble: for since the whole polygons are equimultiples of their triangles, as is evident, they will assuredly have the same ratio as the triangles themselves [Margin: n. *Elements* V.15].

Diagram. Two regular hexagons inscribed in circles, each divided into six triangles by radii from the centre.

- Hexagon ABCDEF inscribed in a circle with centre N: A (upper left), B (left), C (lower left), D (lower right), E (right), F (upper right); centre N, with radii to each vertex — triangle NCD is the lower triangle
- Hexagon GHIKLM inscribed in a circle with centre O: G (upper left), H (left), I (lower left), K (lower right), L (right), M (upper right); centre O, with radii to each vertex — triangle OIK is the lower triangle

[Margin: l. *Elements* III.27] [Margin: m. *Elements* VI.6] [Margin: n. *Elements* V.15]

Furthermore, from this theorem we shall very easily demonstrate that theorem which we have already shown by another method in the scholium of Prop. 4 of Book 2. Namely:

If one straight line is double another straight line, the square of the former will be quadruple the square of the latter; and conversely, if a square is quadruple a square, the side of the former will be double the side of the latter.

Clavius's demonstration. First, let the straight line A be double the straight line B. I say that the square of A is quadruple the square of B. For since all squares are similar, as is clear from Definition 1 of this book, the ratio of the square of A to the square of B will, by this present proposition, be the duplicate of the ratio of the corresponding sides A and B; and since these have to one another a double ratio, the ratio of the squares will be quadruple. For a quadruple ratio is the duplicate of a double ratio, as appears here: 1, 2, 4.

(Continuation of the Scholium to Proposition 20 — the converse of the "line double $\Rightarrow$ square quadruple" theorem, begun in the preceding pages.)

Next, let the square of A be quadruple the square of B. I say that the side A is double the side B. For since the ratio of the squares, which is assumed to be quadruple, is the duplicate of the ratio of the corresponding sides (as has been said), the corresponding sides A and B will have a double ratio; for a quadruple ratio is the duplicate of a double ratio, as is clear in the example already brought forward.

And so, if the ratio of side AB to side FG in the polygons we described in the proposition is expressed in numbers — say, as 5 to 4 — we shall also come to know, by this Proposition 20, in numbers, what ratio polygon ABCDE has to polygon FGHIK. For if the ratio 5 to 4 is continued through three numbers, in this

way — 25, 20, 16 — polygon will be to polygon as 25 to 16. This ratio has a denominator [i.e. quotient] of $1 \frac{9}{16}$. For since the ratio 25 to 16 is the duplicate of the ratio 25 to 20, or 5 to 4, which the corresponding sides AB, FG are assumed to have, and since it has been demonstrated in this theorem that the polygons too have the duplicate ratio of that which their corresponding sides have, polygon will be to polygon as 25 to 16. The same denominator of the ratio of the polygons is found if the denominator of the ratio of the corresponding sides — namely $1 \frac{1}{4}$ — is multiplied into itself; for the number produced is $\frac{25}{16}$, that is, $1 \frac{9}{16}$, which will be the denominator of the ratio said to be the duplicate of that which the corresponding sides have (from what we wrote in Definition 10 of Book V). And accordingly the denominator of the ratio of the polygons, since it too is the duplicate of the same ratio of the corresponding sides.

So too, if the corresponding sides had a tenfold ratio, the polygons would have a hundredfold ratio, since this is the duplicate of that, as is clear here: 100, 10, 1. Or again, because the denominator 10 of the tenfold ratio, multiplied into itself, produces the denominator 100 of the hundredfold ratio, which is called the duplicate of the tenfold.

Diagram. Two squares side by side illustrating the numerical example, the larger about twice the linear size of the smaller.

- B: the smaller square (right)

THEOR. 15. PROPOS. 21.

Figures that are similar to the same rectilinear figure are also similar to one another.

Let the rectilinear figures ABC and DEF be similar to the rectilinear figure GHI. I say that they are also similar to one another. For since, by reason of their similarity, the angles of figure ABC are equal to the angles of figure GHI, and for the same reason the angles of figure DEF are equal to the angles of the same figure GHI, [Margin: a — Common Notion 1 (I, pron. 1)] the angles of figure ABC will therefore be equal to the angles of figure DEF. Again, since by the same similarity the sides of figure ABC are proportional to the sides of figure GHI — namely those about the equal angles — and likewise, for the same reason, the sides of figure DEF are proportional to the sides of the same figure GHI, [Margin: b — V.11] the sides of figure ABC will also be proportional to the sides of figure DEF, namely those which contain equal angles. And so, by the definition, figures

ABC and DEF are similar. Therefore figures that are similar to the same rectilinear figure are also similar to one another. Which was to be shown.

[Margin: xx.]

Diagram. Three triangles standing on a common baseline: a large triangle on the left, a small triangle in the middle, and a triangle on the right. Figures ABC and DEF are each similar to the middle figure GHI.

- A: apex of the large left triangle
- B: bottom-left vertex of the large triangle
- C: bottom-right vertex of the large triangle
- G: apex of the small middle triangle
- H: bottom-left vertex of the middle triangle
- I: bottom-right vertex of the middle triangle
- D: apex of the right triangle
- E: bottom-left vertex of the right triangle
- F: bottom-right vertex of the right triangle

THEOR. 16. PROPOS. 22.

If four straight lines are proportional, the rectilinear figures similar and similarly described upon them will also be proportional. And if the rectilinear figures similar and similarly described upon the straight lines are proportional, the straight lines themselves will also be proportional.

Let there first be four straight lines AB, CD, EF, GH that are proportional, so that as AB is to CD, so is EF to GH. Upon AB and CD let there be constructed any two similar and similarly described rectilinear figures ABI, CDK; and likewise upon EF, GH two others, any similar and similarly described rectilinear figures EFML, GHON. I say that these figures too are proportional, so that as ABI is to CDK, so is EM [EFML] to GO [GHON].

[Margin: a — VI.11] For let a third proportional P be found to the straight lines AB, CD, and a third proportional Q to the straight lines EF, GH. Then as AB is to P, so is EF to Q. But as AB is to P, so is the rectilinear figure ABI to the rectilinear figure CDK — since they are similar and similarly described — by the corollary of Proposition 20 of this book, or, if they are triangles, by the corollary of Proposition 19. [Margin: b — V.22] And it will be, by equality [*ex aequo*], that as the figure ABI is to the figure CDK, so is the figure EM to the figure GO. By the

same reasoning, as EF is to Q, so is EM to GO. [Margin: c — V.11] Therefore, as ABI is to CDK, so is EM to GO. Which is what was proposed.

Next, let ABI, CDK, EM, GO be proportional rectilinear figures. I say that the four straight lines AB, CD, EF, GH are also proportional, so that as AB is to CD, so is EF to GH. [Margin: d — VI.12] For let a fourth proportional RS be found to the three straight lines AB, CD, EF, and upon it let a rectilinear figure RSVT be described, similar and similarly placed to the figure EM. [Margin: e — VI.21] Since, then, as AB is to CD, so is EF to RS, it will also be — as has already been shown — that as ABI is to CDK, so is EM to RV [RSVT]. But as ABI is to CDK, so too is EM to GO by hypothesis. [Margin: f — V.11] Therefore as EM is to RV, so is EM to GO; and consequently RV and GO are equal. Since these are similar and similarly placed, they will necessarily stand — as we shall show presently — upon equal straight lines RS and GH. [Margin: g — V.9] Hence RV and GO are equal. [Margin: h — V.7] Therefore as EF is to RS, so is EF to GH. But EF was set as to RS in the ratio of AB to CD. [Margin: i — V.11] Therefore it will also be that as AB is to CD, so is EF to GH. Wherefore, if the four straight lines are proportional, etc. Which was to be demonstrated.

[Margin: xxi.]

Diagram. A compound figure illustrating Proposition 22. Four straight line-segments each carry a similar figure: triangles ABI and CDK are described on segments AB and CD; four-sided figures EFML and GHON are described on segments EF and GH. Third proportionals P (to AB, CD) and Q (to EF, GH) are drawn as short segments, and a fourth proportional RS bears the four-sided figure RSVT.

- A, B: endpoints of segment AB (base of triangle ABI)
- I: apex of triangle ABI
- P: third-proportional segment (of AB, CD)
- C, D: endpoints of segment CD (base of triangle CDK)
- K: apex of triangle CDK
- Q: third-proportional segment (of EF, GH)
- E, F: bottom vertices of the four-sided figure on EF
- L, M: top vertices of that figure (L left, M right)
- G, H: bottom vertices of the four-sided figure on GH
- N, O: top vertices of that figure (N left, O right)
- R, S: endpoints of the fourth-proportional segment RS
- T, V: top vertices of the four-sided figure RSVT (T left, V right)

LEMMA.

That equal rectilinear figures, similar and similarly described — such as GO and RV — stand upon equal straight lines is shown thus. For if the straight lines GH, RS are unequal, let GH be the greater. Since, then, on account of the similarity of the figures, GH is to HO as RS is to SV, and since GH is set greater than RS, HO will also be greater than SV; and therefore the rectilinear figure GO will be greater than the rectilinear figure RV, seeing that the latter can be placed within the former — which is absurd, since it is contrary to the hypothesis. Therefore the straight lines GH, RS are not unequal. Which is what was proposed.

Otherwise. Let there be two rectilinear figures ABC, DEF, equal and similar and similarly placed. I say that the corresponding sides — such as the straight lines AB, DE — are equal. For if they be not believed equal, let AB be greater than DE, and let a third proportional G be found to the straight lines AB, DE. Since, then, as AB is to DE, so is DE to G, and AB is greater than DE, DE will also be greater than G, and therefore AB much greater than G. But as AB is to G, so is the rectilinear figure ABC to the rectilinear figure DEF, by the corollary of Proposition 19 or 20 of this book. Since, then, AB is greater than G, the rectilinear figure ABC will also be greater than the rectilinear figure DEF — which is absurd, since it was assumed equal. Therefore AB is not a greater straight line than DE. Neither will it be less, by the same reasoning; for then the rectilinear figure ABC would be shown less than the rectilinear figure DEF, which is contrary to the hypothesis. Therefore the straight lines AB, DE are equal.

Diagram. Two similar house-shaped (pentagonal) rectilinear figures side by side, with a separate horizontal segment G drawn above them (the third proportional).

- G: the separate segment above the figures
- A: bottom-left vertex of the left figure
- B: bottom-right vertex of the left figure
- C: upper vertex of the left figure
- D: bottom-left vertex of the right figure
- E: bottom-right vertex of the right figure
- F: upper vertex of the right figure

SCHOLIVM.

In the same way, if there are three proportional straight lines, the rectilinear figures similar and similarly described upon them will also be proportional, and so on. For if the middle line is taken, and its figure taken twice, there will be four

proportional straight lines, and hence four proportional rectilinear figures, as Euclid here demonstrated. Since, then, what is described upon the second line is equal to what is described upon the third — indeed, it is the very same — what is proposed is manifest.

Diagram. A row of similar triangles illustrating the three-proportionals case: a triangle on the first line, the figure of the middle line drawn twice, and a triangle on the third line.

- A, B: base of the first triangle
- G [?]: apex of the first triangle (apex letter at the resolution floor)
- C, D: base of the two middle triangles (each drawn on line CD)
- N: apex of each of the two middle triangles
- E, F: base of the last triangle
- I: apex of the last triangle

A shorter proof. This whole proposition will be demonstrated more expeditiously in this way. Let it first be posited that as AB is to CD, so is EF to GH. I say that it is also as ABI is to CDK, so is EM to GO. [Margin: a — VI.19 or 20] For since the ratio of figure ABC to CDK is the duplicate of the ratio AB to CD, and likewise the ratio of figure EM to figure GO is the duplicate of the ratio EF to GH, [Margin: d] the ratios ABI to CDK and EM to GO will be equal, seeing that they are the duplicates of equal ratios AB to CD and EF to GH. Which is the first point.

Let it next be posited that as ABI is to CDK, so is EM to GO. I say that it is also as AB is to CD, so is EF to GH. [Margin: b — VI.19 or 20] For since the ratio ABI to CDK is the duplicate of the ratio AB to CD, and likewise the ratio EM to GO the duplicate of the ratio EF to GH, the ratios AB to CD and EF to GH will be equal, seeing that their duplicates — ABI to CDK and EM to GO — are set equal. Which is the second point.

Diagram. The reconstruction of the Proposition-22 figure for the shorter proof: triangles ABI and CDK with a segment P; four-sided figures on EF and GH with top vertices L, M and N, O; the square RSVT with top vertices T, V; and a segment Q.

- I: apex of triangle ABI; A, B: its base
- P: segment

THEOR. 17. PROPOS. 23.

Equiangular parallelograms have to one another the ratio compounded of the ratios of their sides.

Let AC and CF be equiangular parallelograms, having the angles BCD, ECG equal. I say that their ratio is compounded of the two ratios which the two sides of the one about the equal angle have to the two sides of the other about the equal angle — the antecedents of the ratios being in the one parallelogram and the consequents in the other. That is, the ratio of parallelogram AC to parallelogram CF is compounded of the ratios of side BC to CG and of side DC to CE; or else of the ratios of side BC to CE and of side DC to CG. That is, if three straight lines I,

K, L are taken, such that I is to K as side BC is to side CG, and K to L as side DC is to side CE, then the parallelogram AC will be to the parallelogram CF as the straight line I is to the straight line L. And accordingly, since the ratio of AC to CF is said to be compounded of the ratios I to K and K to L, that is, of the ratios BC to CG and DC to CE.

For let the parallelograms be joined so as to be about equal angles, so that BC and CG make one straight line. Then, since the angles BCD, ECG are equal, DC and CE will also be one straight line, as we proved above (at Proposition 15 of Book I, from Proclus [Proclus]). Let AD, FG then be produced until they meet at H. Taking any straight line I, [Margin: a — VI.11] let a fourth proportional K be found to the three lines BC, CG, and I; and likewise a fourth proportional L to the three lines DC, CE, and K. Since, then, [Margin: b — VI.1] as BC is to CG, so is AC to CH, and as BC is to CG, so is I set to K, [Margin: c — V.11] it will also be that as AC is to CH, so is I to K. And by the same argument you will show that as HC is to CF, so is K to L; for as DC is to CE, [Margin: d — VI.1] so is HC to CF. Since, then, K has been set to L as DC to CE, HC will also be to CF as K to L. [Margin: e — V.22] Therefore, by equality, it will be that as AC is to CF, so is I to L. But the ratio I to L, by Definition 5 of this book, is compounded of the ratios BC to CG and DC to CE. Out of these same ratios, therefore, will the ratio of parallelogram AC to parallelogram CF also be compounded. By the same reasoning we shall show that the ratio of AC to CF is compounded of the ratios BC to CE and DC to CG — provided the parallelograms are so joined about the equal angles that BC, CE make one straight line, and so on. Therefore equiangular parallelograms have to one another the ratio, etc. Which was to be shown.

Diagram. Two equiangular parallelograms AC and CF joined at the common vertex C, with AD and FG produced to meet at H; three auxiliary segments I, K, L are drawn below.

- A: top-left vertex
- D: top-middle vertex
- H: top-right vertex (meeting-point of produced lines)
- B: mid-left vertex
- C: central common vertex
- G: mid-right vertex
- E: lower vertex (below C)
- F: bottom-right vertex
- I, K, L: the three auxiliary segments below the figure

SCHOLIUM.

The same will be demonstrated more readily in this way. Let the parallelograms be joined as before. [Margin: f — VI.1] Since it is as AC is to CH, so is BC to CG, and as CH is to CF, so is DC to CE, and since the ratio of AC to CF is compounded, by the definition, of the intermediate ratios AC to CH and CH to CF, the same ratio of AC to CF will also be compounded of the ratios BC to CG and DC to CE, which are equal to those intermediates. Which is what was proposed.

Euclid also demonstrates this proposition arithmetically in Book VIII, Proposition 5.

And so, if the ratios of the sides — namely BC to CG and DC to CE — are known in numbers, we shall likewise come, from this Proposition 23, to the knowledge in numbers of the ratio of parallelogram AC to parallelogram CF, in this way.

[Margin: g — VI.23] Let the ratio BC to CG be the same as 11 to 5, and the ratio DC to CE the same as 7 to 11; and let these two ratios be continued in three numbers, 77, 35, 55, so that 77 is to 35 as 11 is to 5, and 35 is to 55 as 7 is to 11. And since the ratio 77 to 35, together with 35 to 55 — that is, the ratio compounded of the ratios of the sides — gives that as 77 is to 55, so is parallelogram AC to parallelogram CF (because the ratio of the parallelograms is likewise compounded of the same ratios of the sides), the ratio of the parallelograms will have a denominator [quotient] of $1 \frac{2}{5}$.

Now the two given ratios will be continued in three numbers either by those which are demonstrated at Proposition 4 of Book VIII, or else in this way. Given the former ratio, 11 to 5, let it be made that, as 7 is to 11 (which is the latter ratio),

so is 5 to another; and there will be found the number $7\frac{6}{7}$ [?]. Thus there will stand three numbers having those two ratios: 11, 5, $7\frac{6}{7}$ [?]. And if the third be reduced to that single [improper] fraction, $55/7$, and the other two numbers be multiplied by the denominator 7, there will be the two products 77, 35 and the numerator 55 — three whole numbers in the same ratios.

So too, if the ratios of the sides be as 4 to 2 and 3 to 3, these two ratios will be continued in these three numbers, 4, 2, 2; or in these least numbers, 2, 1, 1. And since the first is to the third as double, the ratio of the parallelograms will likewise be double. This is evident from the figure. For if the side BC is divided into 4 equal parts, and CG into 2, but DC into 3 and CE into 3, so that BC has to CG a double ratio, but DC to CE a ratio of equality, as was posited — then, if through the points of division lines are drawn parallel to the sides, the parallelogram AC will contain 12 equal rhombi, but CF only 6; and thus the parallelogram AC will have to the parallelogram CF a double ratio, as was said.

Diagram. The joined parallelograms AC and CF (as before), here subdivided by lines drawn parallel to the sides through the points of division: parallelogram AC is cut into 12 equal rhombi, parallelogram CF into 6.

- A: top-left vertex
- D: top-middle vertex
- H: top-right vertex
- B: mid-left vertex
- C: central common vertex
- G: mid-right vertex
- E: lower vertex
- F: bottom-right vertex

It is also evident that one of the ratios that compose the compound ratio can be greater than the compound ratio itself, and also equal to it. For in the former example the ratio of side BC to CG is as 11 to 5 — that is, one whose denominator is $2\frac{1}{5}$ — which is greater than the ratio of the parallelograms, since the denominator of that is $1\frac{2}{5}$. But in the latter example the ratio of side BC to CG is double, just as the ratio of the parallelograms also is. From this, therefore, it can further be established that this composition of ratios is not an addition, as some interpreters would have it; and likewise that a ratio of greater inequality can be compounded both out of a ratio of lesser inequality and out of a ratio of equality — which those same interpreters deny. For in the former example the ratio of

side DC to CE is one of lesser inequality, but in the latter one of equality. But on this matter we shall write more at the end of Book IX.

In this place Federico Commandino [Federico Commandino] demonstrates certain other things which pertain either to the composition of ratios or are demonstrated from it — matters not without use, which we too have resolved to bring forward, though with the demonstrations somewhat altered. They are as follows.

1.

Triangles which have one angle equal to one angle have to one another the ratio compounded of the sides which contain the equal angle.

Let there be triangles ABC and DEF having angle C equal to angle F. I say that the ratio of triangle ABC to triangle DEF is compounded of the sides — that is, of the ratio of BC to EF together with the ratio of AC to DF; or else of the ratio of BC to DF together with the ratio of AC to EF. For when the parallelograms CG and FH are completed, they will be equiangular, [Margin: a — Elements VI.23] and therefore their ratio will be compounded of the sides. Since, then, the triangles ABC and DEF have the same ratio to those [parallelograms] [Margin: b — Elements I.34] of which they are the halves, [Margin: c — Elements V.15] the ratio of triangle ABC to triangle DEF will likewise be compounded of the ratios of the sides BC, AC to the sides EF, DF.

Diagram. Two parallelograms, each with its diagonals drawn, illustrating the completion of the two triangles into parallelograms CG and FH.

- Left parallelogram (CG, completing triangle ABC): G (top-left), A (top-right), B (bottom-left), C (bottom-right); the diagonal from B to A and a further diagonal are drawn.
- Right parallelogram (FH, completing triangle DEF): H (top-left), D (top-right), E (bottom-left), F (bottom-right), with the point I marked near the base at F; diagonals drawn.

II.

To compound one ratio out of two ratios, or out of several.

How this is done is easily gathered from the demonstration of Proposition 23 of this book. For let there be three ratios — A to B, C to D, and E to F — set out in lines. It is now required to compound a single ratio out of them. [Margin: d — Elements VI.12] Let it be arranged that as A is to B, so G is to H; and as C is to D, so

H is to I; and as E is to F, so I is to K. I say that the ratio of G to K is compounded of the three given ratios. For since it is compounded of the ratios G to H, H to I, and I to K — by Definition 5 of this book — it will also be compounded of the ratios A to B, C to D, and E to F, because these are respectively equal to those.

Diagram. A row of ten vertical straight-line segments of varying lengths, representing the magnitudes named in the demonstration, labelled left to right: A, B, C, D, E, F, G, H, I, K.

III.

To subtract a lesser ratio from a greater.

Let A to B be the lesser ratio, to be subtracted from the greater ratio C to D.
 [Margin: e — Elements VI.12] Let it be arranged that as A is to B, so C is to E; and let E be established as a mean term between C and D. I say that the ratio A to B has been taken away from the ratio C to D, and that the remaining ratio is E to D. For since the ratio C to D is compounded of the ratios C to E and E to D, if the ratio C to E — that is, A to B — is taken away, the ratio E to D will be left.

But this compounding and removal of ratios is not, properly speaking, addition and subtraction; for otherwise the whole would be equal to a part, and less, and a greater ratio could be subtracted from a lesser — as we shall show at the end of Book 9.

Diagram. A column of five horizontal straight-line segments of varying lengths, representing the magnitudes of the demonstration, labelled top to bottom: A, B, C, E, D.

IV.

Triangles which have one angle equal to one angle have the same ratio as the rectangles contained by the sides comprehending the equal angle.

Let there be triangles ABC and DEF having angle A equal to angle D. I say that triangle ABC is to triangle DEF as the rectangle contained by AB, AC is to the rectangle contained by DE, DF. For when the perpendiculars BG and EH are drawn to AC and DF, the triangles ABG and DEH will be equiangular, as is clear from the corollary to Proposition 32 of Book 1, since the two angles A and AGB are equal to the two angles D and DHE. [Margin: f — Elements VI.4] Therefore, as GB is to BA, so HE is to ED. But as GB is to BA, [Margin: g — Elements VI.1] so is the rectangle contained by BG, AC to the rectangle contained by AB, AC (for if GB and BA are taken as bases, they will have the same altitude AC). And by the same

reasoning, as HE is to ED, so is the rectangle contained by EH, DF to the rectangle contained by DE, DF. [Margin: h — Elements V.11] The rectangle contained by BG, AC is therefore to the rectangle contained by AB, AC as the rectangle contained by EH, DF is to the rectangle contained by DE, DF; and, alternately, the rectangle contained by BG, AC is to the rectangle contained by EH, DF as the rectangle contained by AB, AC is to the rectangle contained by DE, DF. But as the rectangle contained by BG, AC is to the rectangle contained by EH, DF, [Margin: i — Elements V.15] so is triangle ABC to triangle DEF, [Margin: k — Elements I.41] because these triangles are the halves of those rectangles (for they have the same bases AC, DF as those rectangles, and the same altitudes BG, EH, and hence are set up between the same parallels as they). Therefore triangle ABC will also be to triangle DEF as the rectangle contained by AB, AC is to the rectangle contained by DE, DF. Which was proposed.

ANOTHER WAY, and more easily. From the first theorem of this scholium, the ratio of triangle ABC to triangle DEF is compounded of the ratios AB to DE and AC to DF. [Margin: l — Elements VI.23] But the ratio of the rectangle contained by AB, AC to the rectangle contained by DE, DF is likewise compounded of the same ratios AB to DE and AC to DF. Therefore triangle ABC will be to triangle DEF as the rectangle contained by AB, AC is to the rectangle contained by DE, DF. Which was proposed.

Diagram. Two triangles, each with a cevian drawn from a base vertex to the foot of a perpendicular on the opposite side.

- Left triangle ABC: A (apex), B (bottom-left), C (bottom-right); G marked on side AC (the foot of the perpendicular BG), with the segment from B to G drawn.
- Right triangle DEF: D (apex), E (bottom-left); the bottom-right vertex and the interior foot-point are labelled F and H, with a segment drawn from E. [The printed placement of the labels F and H appears transposed relative to the demonstration, in which H is the foot of the perpendicular EH on DF and F is a vertex.] [?]

V.

Parallelograms equiangular to one another have the same ratio as the rectangles contained by the sides of them comprehending the equal angle.

Let ABCD and EFGH be parallelograms equiangular to one another, whose angles B and F are equal. I say that as parallelogram BD is to parallelogram FH, so is the

rectangle contained by AB, BC to the rectangle contained by EF, FG. For when the diagonals AC and EG are drawn, subtending the equal angles B and F, the triangles ABC and EFG will have angle B equal to angle F. Therefore, as we have already demonstrated, as triangle ABC is to triangle EFG, so is the rectangle contained by AB, BC to the rectangle contained by EF, FG. [Margin: m — Elements V.15] Since, then, the parallelograms BD and FH have the same ratio as the triangles ABC and EFG — [Margin: n — Elements I.34] because these are the halves of them — [Margin: o — Elements V.11] it will also follow that as parallelogram BD is to parallelogram FH, so is the rectangle contained by AB, BC to the rectangle contained by EF, FG. Which was proposed.

Diagram. Two equiangular parallelograms, each with a diagonal drawn to form the triangles ABC and EFG.

- Left parallelogram ABCD: A (top-left), D (top-right), B (bottom-left) [?], C (bottom-right); diagonal AC drawn.
- Right parallelogram EFGH: F (top-left), H (top-right), E (bottom-left) [?], G (bottom-right) [?]; diagonal EG drawn.

VI.

Triangles and parallelograms have to one another a ratio compounded of the ratio of the bases and the ratio of the altitudes.

Let there be triangles ABC and DEF and parallelograms CG and EH, whose altitudes are AI and DK. I say that their ratio is compounded of the ratio of the base BC to the base EF and the ratio of the altitude AI to the altitude DK. First let the altitudes be equal, but the bases either equal or unequal. Let it be arranged that as BC is to EF, so L is to M; and as AI is to DK, so M is to N. This being done, M will be equal to N, since AI too is assumed equal to DK. [Margin: p — Elements V.7 (?)] And accordingly L will be to N as L is to M — that is, as BC is to EF. [Margin: q — Elements VI.1] But as BC is to EF, so is triangle ABC to triangle DEF, and parallelogram CG to parallelogram EH. [Margin: r — Elements V.11] Therefore it will also follow that as L is to N, so is triangle ABC to triangle DEF, and parallelogram CG to parallelogram EH. But the ratio of L to N is compounded of the ratio L to M — that is, of the ratio of the base BC to the base EF — and of the ratio M to N — that is, of the ratio of the altitude AI to the altitude DK. The ratio, therefore, of triangle ABC to triangle DEF, and of parallelogram CG to parallelogram EH, is compounded of the same ratios. Which was proposed.

Diagram. A compound figure for the first case (equal altitudes): the parallelogram CG with its inscribed triangle ABC (altitude AI, foot I on base BC),

and the parallelogram EH with its inscribed triangle DEF (altitude DK, foot K on base EF); to the right, three vertical auxiliary segments labelled L, M, N.

- Left group: G (top-left), A (apex of triangle), B (bottom-left), I (foot of altitude AI), C (bottom-right).
- Right group: D (apex), H (top-right), E (bottom-left), K (foot of altitude DK) [?], F (bottom-right).
- Auxiliary segments: L, M, N.

Now let the altitudes AI and DK be unequal, with AI the greater; and the bases BC, EF either equal or unequal. Let it be arranged that as AI is to DK, so O is to P; and as BC is to EF, so P is to Q. Then, cutting off IL equal to DK, draw through L the line LM parallel to BC, cutting AC in N, and join the straight line BN. Since, then, triangle ABC is to triangle NBC, and parallelogram CG to parallelogram CM, as the altitude AI is to the altitude IL — or to DK, which is equal to IL — that is, as O is to P, by what we showed from Commandino [Federico Commandino] at Proposition 1 of this book (since the triangles and parallelograms have the same base BC); and since triangle NBC is to triangle DEF, and parallelogram CM to parallelogram EH, [Margin: s — Elements VI.1] as the base BC is to the base EF (the altitude being the same) — that is, as P is to Q — [Margin: t — Elements V.22] it will follow *ex aequo* that ABC is to DEF, and CG to EH, as O is to Q. Therefore, since the ratio O to Q is compounded of the ratio O to P — that is, of the ratio of the altitude AI to the altitude DK — and of the ratio P to Q — that is, of the ratio of the base BC to the base EF — the ratio of triangle ABC to triangle DEF, and of parallelogram CG to parallelogram EH, will be compounded of the same ratios. Which was proposed.

In the same way it will be shown that the ratio of triangle DEF, whose altitude is the less, to triangle ABC, and of parallelogram EH to parallelogram CG, is compounded of the ratio of the base EF to the base BC and the ratio of the altitude DK to the altitude AI. For if it be arranged that as EF is to BC, so Q is to P; and as DK is to AI, so P is to O; and the rest be done as before, [Margin: u — Elements VI.1] then triangle DEF will be to triangle NBC, and parallelogram EH to parallelogram CM, as EF is to BC — that is, as Q is to P. Likewise triangle NBC will be to triangle ABC, and parallelogram CM to parallelogram CG, as LI (or DK) is to AI — that is, as P is to O — from what we demonstrated from Commandino at Proposition 1 of this book. [Margin: x — Elements V.22] Therefore *ex aequo* it will follow that as DEF is to ABC, and EH to CG, so Q is to O. Wherefore, since the ratio Q to O is compounded of the ratio Q to P — that is, of the ratio of the base EF to the base CB — and of the ratio P to O — that is, of the ratio of the altitude DK to

the altitude AI — the ratio of DEF to ABC, and of EH to CG, will also be compounded of the same ratios. Which was proposed.

Diagram. A compound figure for the second and third cases (unequal altitudes): the parallelogram CG with triangle ABC and the inscribed line LM (cutting AC in N, with BN joined), and the parallelogram EH with triangle DEF; to the right, three vertical auxiliary segments O, P, Q.

- Left group: G (top-left), A (apex), L, N (on AC), M; B (bottom-left), I, C (base).
- Right group: D (apex), H (top-right); E, K, F along the base.
- Auxiliary segments: O, P, Q.

[Several small vertex-letters in this crowded figure are at the resolution floor]

THEOR. 18. PROPOS. 24.

[Margin: xxii.]

In every parallelogram, the parallelograms about the diameter are similar both to the whole and to one another.

Let ABCD be a parallelogram, in which the diameter AC is drawn, and through any point I of it let two straight lines EF, GH be drawn parallel to the sides of the parallelogram. I say that the parallelograms EG [?] and FH about the diameter are similar both to the whole parallelogram and to one another. That they are equiangular with the whole is easily shown. For angle GAE is the same as angle BAD; [Margin: a — Elements I.29] and the exterior angle AEI is equal to the interior ADC; and the exterior angle AGI to the interior BFI; and this exterior to the interior BCD. Therefore parallelogram EG is equiangular with parallelogram BD; and by the same reasoning FH will be equiangular with BD. That the sides about the equal angles are proportional to the sides of the whole we shall demonstrate as follows. Since triangle AGI is equiangular with triangle

triangle ABC, and triangle AEI with triangle ADC, as is evident from Proposition 29 of Book 1, or also from the corollary to Proposition 4 of this book, [Margin: b — Elements VI.4] it will follow that as AB is to BC, so AG is to GI, and thus the sides about the equal angles B and G are proportional. Again, [Margin: c — Elements VI.4] it will follow that as BC is to CA, so GI is to IA; likewise as CA is to CD, so IA is to IE. [Margin: d — Elements V.22] Therefore *ex aequo*, as BC is to CD, so is GI to IE, and hence the sides about the equal angles BCD, GIE are proportional. In no other way will it be demonstrated that the sides about the remaining equal angles are proportional. Therefore, by the definition, parallelogram EG will be similar to

the whole parallelogram BD. By the same technique you will show that parallelogram FH is similar to the same parallelogram BD; [Margin: e — Elements VI.21] and thus they will also be similar to one another. Therefore in every parallelogram the parallelograms about the diameter are [similar], etc. Which was to be demonstrated.

Diagram. A parallelogram with diameter and two internal lines forming the parallelograms about the diameter.

- A (top-left), E (top-middle), D (top-right).
- G (left-middle), I (centre, on the diameter), H (right-middle).
- B (bottom-left), F (bottom-middle), C (bottom-right).
- The diameter runs from A (top-left) to C (bottom-right); the line EF runs vertically (E to F) and GH horizontally (G to H), crossing at the point I on the diameter.

SCHOLIUM.

It must be understood, however, that the parallelograms about the diameter of the whole are such as have one angle in common with the whole parallelogram, as is manifest from the form of the demonstration.

Now if, about the produced diameter of some parallelogram, another parallelogram stands — such that two of its sides form straight lines with two sides of the other, or at least are parallel to them — it will be shown by nearly the same means that this is similar to that. For let BD be the diameter of parallelogram ABCD, produced to F, and about it let there stand a parallelogram DEFG whose two sides DE, DG form straight lines with AD, DC, the sides of parallelogram AC. I say that parallelogram GE is similar to parallelogram AC. That the two are equiangular with each other is easily shown. [Margin: f — Elements I.29] For since angle A is equal to the alternate angle ADG, and to this the alternate angle G is likewise equal, the angles A and G will be equal. [Margin: g — Elements I.34] Wherefore their opposites C and E will also be equal. [Margin: h — Elements I.15] Again, since the angles ADC, GDE at the vertex are equal, [Margin: i — Elements I.34] their opposites ABC, GFE will also be equal to these. Therefore the parallelograms GE, AC are equiangular. That the sides about the equal angles are proportional will be made clear as follows. Since triangle BAD is equiangular with triangle DGF, and triangle BCD with triangle DEF, [Margin: k — Elements VI.4] it will follow that as BA is to AD, so DG is to GF. Again, as AD is to DB, so GF is to FD; and as DB is to DC, so FD is to FE; [Margin: l — Elements V.22] and therefore *ex aequo*, as AD is to DC, so GF is to FE. The sides about the angles A,

ADC are therefore proportional to the sides about the angles G, GFE, which are equal to them. In the same way you will show that the remaining sides about the equal angles are proportional. Therefore the parallelograms AC, GE are similar.

And if about the same diameter there stands a parallelogram HIKF having its sides parallel to the sides of parallelogram AC, the same will be demonstrated. For when AD, CD are produced until they meet the straight lines FK, FH produced in E and G, HK will be similar to GE, [Margin: m — Elements VI.24] as Euclid demonstrated; but AC too is similar to the same GE, as we have just shown. [Margin: n — Elements VI.21 (?)] Therefore HK and AC are also similar to one another. Which was proposed.

But let us also, following Peletier [Jacques Peletier], dispatch the following problem.

Diagram. The scholium's figure for the two joined parallelograms DEFG standing about the produced diameter BD of ABCD. Readable labels include A, B, C, D (parallelogram ABCD), the produced diameter through the vertex region, and the outer parallelogram vertices E, F, G. [Small vertex-letters at the resolution floor]

Given two equiangular but dissimilar parallelograms: from either of them to cut off one similar to the other.

Let ABCD and CEFG be two equiangular but dissimilar parallelograms, and from ABCD let a parallelogram similar to CEFG be cut off. Let the two be joined at the equal angles BCD, ECG, so that BCG is one straight line, and consequently — as was demonstrated at Proposition 15 of Book 1 — ECD is likewise one straight line. Then, the diameter FC having been drawn, let it be produced until at H it cuts either side AD or side AB (for it will not fall on the point A, since AC would then be similar to CF, as has been demonstrated, which is contrary to the hypothesis); and through H let HI be drawn parallel to AB or to AD. I say that the parallelogram HC cut off is similar to CF. For if the whole parallelogram KL be completed, HC and CF will be about the diameter. Therefore they will be similar to one another, as Euclid demonstrated in this proposition.

By nearly the same technique either of them can also be enlarged so as to become similar to the other. For let ABCD be enlarged so as to become similar to CEFG: let it be joined as before, and let the diameter FC be extended until at H it cuts either side BA produced or side DA produced (for it will not fall on the point A, since AC would then be similar to CF, as has been demonstrated, which is not the case supposed). Then through H let HI be drawn parallel to AD or to AB, until it cuts either side CD produced or CB produced in I. I say that the enlarged

parallelogram HC is similar to parallelogram CF. For if the whole parallelogram KL be completed, HC and CF will stand about the diameter; [Margin: o — Elements VI.24] wherefore they will be similar to one another.

Diagram. Two pairs of parallelogram figures for the Peletier problem — the first pair illustrating the cutting-off (abscission) construction, the second the enlargement (augmentation). Readable labels across the figures include A, B, C, D, E, F, G, H, I, K, L, with the diameter FC drawn and the completed parallelogram KL indicated. [Many small vertex-letters at the resolution floor]

Euclid, *Elements* Book VI (Clavius's commentary) — continued

(Continuing the scholium appended to Proposition 24: the Peletier problem of cutting off or enlarging a parallelogram similar to a given one.)

It is clear, both from Euclid's demonstration of this theorem and from the proof of the theorem we proposed in this scholium, that parallelograms about the same diameter are not only similar but also similarly situated. Therefore, given any parallelogram ABCD, if a larger one is to be described similar to it and similarly situated, one side must be extended — namely BC. Then, from E (any point beyond C), draw EF parallel to CD, cutting the diameter BD (extended) at F; and through F draw FG parallel to AD, meeting the line BA (extended) at G. [Margin: p — *Elements* VI.24] For the parallelogram GE will then be similar and similarly situated to AC, and larger than it. But if a smaller one is to be described, the point E must instead be taken on the near side of C, and the rest carried out as before, as the figure indicates.

Diagram. A parallelogram with one side extended, illustrating both the enlargement and the reduction of a given parallelogram similar to itself. A diagonal runs from the lower-left corner B upward to the outer corner F at the upper right; the original parallelogram lies inside, the enlarged one outside.

- G (upper left): outer corner of the enlarged parallelogram
- F (upper right): outer corner, on the extended diagonal
- A (left, below G): upper-left corner of the original ABCD
- D (upper middle): upper-right corner of the original
- F (interior, on the diagonal), G (interior, lower-left corner): printed duplicate letters (as in the source), marking the reduction case

- B (lower left): base corner
- E (lower, between B and C): the point taken short of C (reduction case)
- C (lower middle): corner of the original
- E (lower right): the point taken beyond C (enlargement case)

PROBL. 7. PROPOS. 25. [Margin: xxv.]

Given a rectilinear figure, to construct another that is similar and similarly situated to it, and equal to a second given figure.

Let two rectilinear figures A and B be given, and let another rectilinear figure be constructed that is similar to A but equal to B. On CD, one side of the figure to which the new one is to be made similar, [Margin: a — *Elements* I.44 or 45] construct a parallelogram CE, at any angle, equal to the rectilinear figure A. And on the straight line DE, at the angle EDG (which is equal to angle DCF), [Margin: b — *Elements* VI.13] construct a parallelogram DH equal to B; then both CDG and FEH will each form a single straight line, as was demonstrated in Proposition 45 of Book I. Now let IK be found as the mean proportional between the straight lines CD and DG, [Margin: c — *Elements* VI.18] and on IK construct a rectilinear figure L similar and similarly situated to A. I say that L is equal to the other figure B.

For since the three straight lines CD, IK, DG are proportional, by the corollary of Proposition 19 or 20 of this book, as CD (the first) is to DG (the third), so is A — the figure described on the first side CD — to L, the figure similarly described on the second, IK. [Margin: d — *Elements* VI.1] But as CD is to DG, so is the parallelogram CE to the parallelogram DH, since they have the same height. [Margin: e — *Elements* V.11] Therefore as CE is to DH, so is A to L. [Margin: f — *Elements* V.7] But as CE is to DH, so is A to B, since the parallelogram CE was constructed equal to the figure A, and the parallelogram DH equal to the figure B. [Margin: g — *Elements* V.11] Therefore as A is to B, so is A to L; [Margin: h — *Elements* V.9] and consequently the figures B and L are equal. But L is also, by construction, similar and similarly situated to A. Therefore, given a rectilinear figure, we have constructed another similar and similarly situated to it and equal to a second given figure. Which was to be done.

Diagram. The construction for Proposition 25. At the upper left is the given pentagon A standing on the base line through C, D and G; to its right is the given triangle B. Below is the pair of parallelograms CE and DH set on the straight line CDG with FEH along their base; at the lower centre is the constructed pentagon L standing on the mean proportional IK.

- A (upper-left pentagon): the given figure to which the new one is made similar
- B (upper-right triangle): the second given figure, to which L is made equal
- C, D, G (along the upper base line): the joined bases of the parallelograms CE, DH
- F, E, H (along the lower base line): the far corners of parallelograms CE and DH
- L (lower-centre pentagon): the constructed figure, similar to A and equal to B
- I, K (base of pentagon L): the segment IK, the mean proportional between CD and DG

THEOR. 19. PROPOS. 26. [Margin: xxiii.]

If from a parallelogram a parallelogram is taken away that is similar to the whole and similarly situated, having a common angle with it, then it lies about the same diameter as the whole.

From the parallelogram BD let a parallelogram EG be cut off, similar to it and similarly situated, having the common angle EAG with it. I say that EG lies about the diameter of the whole BD.

For let the straight lines AF and CF be drawn. If these form a single straight line, it is clear — since AF is the diameter of EG and AC the diameter of BD — that the parallelogram EG lies about the diameter AFC of the whole parallelogram. But if AF and CF are said not to form a straight line, draw AC, the diameter of the whole parallelogram, cutting the side EF at the point H; and through H draw HI parallel to FG. Now since the parallelograms BD and EI lie about the same diameter AHC, [Margin: a — *Elements* VI.24] they are similar and similarly situated. [Margin: b — *Elements* VI, def. 1] Therefore as BA is to AD, so is EA to AI. But as BA is to AD, so also is EA to AG, since the parallelograms BD and EG are likewise assumed to be similar and similarly situated. [Margin: c — *Elements* V.11] Therefore as EA is to AI, so is EA to AG; [Margin: d — *Elements* V.9] and consequently the lines AI and AG are equal — the part and the whole — which is absurd.

But if AHC is said to cut the other side FG, then, when HI is drawn parallel to EF, [Margin: e — *Elements* VI.24] the parallelograms BD and IG are again similar and similarly situated. [Margin: f — *Elements* VI, def. 1] Therefore as DA is to AB, so is GA to AI. But as DA is to AB, so also is GA to AE, because of the similarity of the parallelograms BD and EG. [Margin: g — *Elements* V.11] Therefore as GA is to AI, so is GA to AE; [Margin: h — *Elements* V.9] and consequently the lines AI and AE

are equal — the part and the whole — which is absurd. Therefore the lines AF and FC form a single straight line; that is, the diameter AC, when drawn, passes through the point F, and the diameter AF, when drawn, falls on the point C. And so, if from a parallelogram a parallelogram is taken away, and so on. Which was to be demonstrated.

Diagram. First figure for Proposition 26 — the parallelogram BD with the cut-off parallelogram EG, the diameter AC cutting the side EF at H.

- B (upper left), C (upper right): two corners of the whole parallelogram BD
- A (lower left), D (lower right): the remaining corners; AC is the diameter
- H (interior, on the diameter): where AC meets EF
- F (interior, right of H): corner of the cut-off parallelogram EG
- I (lower, between A and G): foot of HI
- G (lower middle): corner on the base AD

Diagram. Second figure for Proposition 26 — the case in which AHC cuts the side FG.

- B (upper left), C (upper right): corners of the whole parallelogram
- A (lower left), D (lower right): remaining corners; AC is the diameter
- E (left side): corner of the cut-off parallelogram
- I (left side, below E): foot of HI
- F (interior, upper): corner of EG
- H (interior, lower): where the diameter meets FG
- G (lower middle): point on the base

SCHOLIUM

We shall demonstrate the same theorem in another way, directly, as follows. Let the sides AB and BC be bisected at the points H and I — whether the point H falls on the point E, or above it, or below it — and draw the straight lines HI and AE. Now since, because of the similarity of the parallelograms, as AB is to BC so is AE to EF; [Margin: i — *Elements* V.15] and since, as the whole AB is to the whole BC, so is the half HB to the half BI, [Margin: k — *Elements* V.11] it follows that as HB is to BI, so is AE to EF. Therefore the triangles HBI and AEF — since about the equal angles B and E (which are equal because of the similarity of the parallelograms BD and EG; [Margin: l — *Elements* I.30] or because the one is interior and the other exterior with respect to the parallels BC and EF, which are parallel since

each is parallel to AD) they have proportional sides — [Margin: m — *Elements* VI.6] will be equiangular, and will have the angles BHI and EAF equal, the exterior and the interior between the lines HI and AF. [Margin: n — *Elements* I.28] Therefore the lines HI and AF are parallel. But the straight line conceived as drawn from the point A to the point C [Margin: o — *Elements* VI.2] is also parallel to HI, because the sides AB and BC of the triangle ABC then constructed would be cut proportionally at H and I, being bisected; and it passes through the point F, since from the point A only one line can be drawn parallel to HI, as is evident. Therefore the parallelograms BD and EG, similar and similarly situated, lie about the same diameter AFC. Which is what was proposed.

Diagram. Three small parallelograms (printed rotated 90°) illustrating the three cases of the ostensive proof — the bisection-point H falling on E, above E, or below E. Each shows the whole parallelogram BD with its diagonal, the cut-off parallelogram EG, and the auxiliary lines HI and AE.

- A, B, C, D: the corners of the whole parallelogram (diagonal AC)
- E, F, G: the cut-off parallelogram EG with inner corner F
- H (on AB), I (on BC): the bisection points; HI joins them
- (The three figures repeat these labels for the three positions of H relative to E.) [?]

But if two similar and similarly situated parallelograms do not have a common angle, but one lies outside the other — yet connected to each other along two of their equal angles in such a way that two sides of the one form two straight lines with two sides of the other — we shall demonstrate, by almost the same means, that they lie about the same diameter. Let there be two similar and similarly situated parallelograms BD and EG, joined at the equal angles BCD and GCE so that the lines BC and CG lie in one straight line; and for this reason, by what we showed at Proposition 15 of Book I, the lines DC and CE also form a single straight line. I say that the parallelograms BD and EG lie about the same diameter — that is, that the diameter AC together with the diameter FC forms one straight line.

For if AC and FC do not form one straight line, draw from A to F a straight line cutting BC at the point H, and through H draw HI parallel to CD, meeting the line FE (extended) at K. Now since the parallelograms BI and KG lie about the same diameter AHF (extended), and the two lines BH, HI together with the two lines HG, HK form two straight lines, they are similar and similarly situated, by what we demonstrated at Proposition 24 of this book. Therefore as HB is to BA, so is FK to KH. [Margin: p — *Elements* V.8] But CB, the greater, has to BA a greater ratio than HB, the lesser, has to the same BA; and as CB is to BA, so is FE to EC, since the

parallelograms BD and EG are assumed similar and similarly described. Therefore FE also has to EC — that is, to KH, which is equal to it — a greater ratio than HB has to BA, that is, than FK has to KH. Consequently, if FE has to KH a greater ratio than FK has to the same KH, [Margin: q — *Elements* V.10] then EF will be greater than FK — the part greater than the whole. Which is absurd.

Diagram. The two similar parallelograms BD and EG joined at C, one outside the other, with the lines BC, CG collinear. A tall rectangle with two diagonals drawn from A upward.

- K (upper left), F (upper middle), F (upper right): the top edge, the two F's a printed duplicate (as in the source), the far F at the tip of the extended diagonal AHF
- B (left), H (interior), C (interior right), G (right): the middle line, BC–CG collinear
- A (lower left), I (lower middle), D (lower right): the base

Diagram. The companion case in which the line AHF cuts the side CD. A cross-shaped configuration of two parallelograms meeting at C.

- B (upper left), C (upper centre), D (upper right): tops of the two joined parallelograms
- I (left), H (centre), K (right): the line HI extended to K
- A (lower left), D (lower right): base corners

But if someone says that the line AHF cuts the side CD, then, drawing through H a line parallel to BC — namely HI, meeting the line FG (extended) at K — the parallelograms ID and EK are again similar and similarly situated, by what we showed at Proposition 24 of this book. Therefore as HD is to DA, so is FK to KH. [Margin: r — *Elements* V.8] But CD has to DA a greater ratio than HD has to DA; and as CD is to DA, so is FG to GC, since the parallelograms BD and EG were granted to be similar and similarly situated. Therefore FG also has to GC — that is, to KH, which is equal to it — a greater ratio than FK has to KH; [Margin: s — *Elements* V.10] and therefore FG will be greater than FK — the part greater than the whole — which is absurd.

The same will be shown directly by this reasoning. Since, because of the similarity of the parallelograms BD and EG, the angles B and E are equal, and as AB is to BC so is CE to EF, the triangles ABC and CEF will have proportional sides about the equal angles B and E; [Margin: t — *Elements* VI.6] and therefore they will be equiangular, and will have the angles BCA and EFC equal. Therefore,

adding the common angle BCF, the two angles BCA and BCF will be equal to the two angles EFC and BCF. [Margin: u — *Elements* I.29] But these, lying between the parallels BC and EF, are equal to two right angles. Therefore BCA and BCF too will be equal to two right angles; [Margin: x — *Elements* I.14] and consequently AC and FC form a single straight line. Which is what was proposed.

Diagram. The figure for the ostensive proof of the previous paragraph — two similar parallelograms BD, EG meeting at C, with the diagonal AC through F.

- E (upper left), F (upper right): top of the upper parallelogram
- B (left), C (centre), G (right): the middle line
- A (lower left), D (lower right): base corners; A–C–F lies along the diagonal

Euclid was right, in his theorem, to require that the parallelogram cut off from the whole be not only similar to the whole but also similarly situated, so that it may be shown to lie about the same diameter as the whole. For if from BD, on its longer side, a longer piece EG is cut off, lying about the same diameter as the whole, [Margin: x — *Elements* VI.24] then EG will be similar and similarly situated. But if, in a rectangle IL that is equilateral and equiangular to BD, one takes HM equal to EF and MN equal to AE, and so on, then the rectangle MO will indeed be equal and similar to the rectangle EG — because of the equality of the sides and of the angles, which are right — and for that reason similar to the rectangle IL; yet, because it is not similarly situated, it will not lie about the same diameter as the whole rectangle IL.

The same thing is also seen here in similar rectangles, one of which lies outside the other, yet connected to each other along their angles in such a way that two sides of the one lie in a straight line with two sides of the other — such as the rectangular parallelograms BD and EG, and IL and MO. Of these, EG lies about the same diameter as the rectangle BD, since it is similarly situated; but MO by no means lies about the same diameter as the rectangle IL, because it is not similarly situated, although it is similar to it — being indeed exactly equal to EG. For KM is equal to EF, and MN to FC, and so on.

Diagram. Rectangle BD with the similarly-situated rectangle EG about its diameter.

THEOR. 20. PROPOS. 27. [Margin: xxvi.]

Of all the parallelograms applied to the same straight line and deficient by parallelogrammic figures similar and similarly situated to that described on the half of the line, the greatest is the one applied to the half — the deficient parallelogram being similar to the defect.

Let a straight line AB be given, bisected at C; and on its half BC construct any parallelogram CDEB, whose diameter is BD. Then, if the whole parallelogram ABEH is completed, the parallelogram AD, standing on the half AC, will be applied along AB, deficient by the parallelogram CE, and will be similar to the defect CE. I say that the parallelogram AD, applied to the half AC and deficient by the parallelogram CE, is the greatest of all those applied along AB and deficient by parallelograms similar and similarly situated to CE.

For take any point G on the diameter BD, and through G draw the lines FGI and KG parallel to AB and BE. Then the parallelogram FK, applied along AB, is deficient by the parallelogram KI, [Margin: a — *Elements* VI.24] which is similar to CE and similarly situated, since it lies about the same diameter as CE. [Margin:

b — *Elements* I.43] Now since the complements CG and GE are equal, if the common KI is added, CI and KE will also be equal. [Margin: c — *Elements* I.36] But CI is equal to CF, because the bases AC and CB are equal. Therefore CF and KE are also equal; and when the common CG is added, the parallelogram AG and the gnomon LM will be equal. Therefore, since CE is greater than the gnomon LM — for CE contains, besides the gnomon, the parallelogram DG as well — AD too, being equal to CE because of the equal bases AC and CB, [Margin: d — *Elements* I.36] will be greater than the parallelogram AG by that same parallelogram DG. And in the same way it will be shown that AD is greater than all parallelograms applied along the line AB in such a way that the point G lies between the points B and D — that is, those which occupy a line greater than the half AC and have a smaller height than AD — provided their defects are similar to CE.

The same — that AD is greater than the parallelogram AG — will be demonstrated another way, as follows. [Margin: c — *Elements* I.36] The parallelograms FD and DI are equal, since the bases HD and DE are equal. But DI is greater than GE — that is, than the complement CG [Margin: f — *Elements* I.43] (which is equal to GE) — by the parallelogram DG. Therefore FD too is greater than CG by that same parallelogram DG. And accordingly, when the common CF is added, AD will be greater than AG by that same parallelogram DG.

Diagram. The principal figure for Proposition 27. The parallelogram ABEH stands on AB (bisected at C); the parallelogram AD is applied to the half AC, deficient by CE; the arbitrary parallelogram FK is deficient by KI about the diameter BD. A small arc (semicircle) is drawn about the point G near L.

- H (upper left), D (upper middle), E (upper right): top edge of the whole ABEH
- F (left side), M, G, I (interior middle row): F on the left, then M, the point G with L just above it, and I toward the right
- L (interior, above G): apex of the drawn arc
- A (lower left), C (lower middle), K, B (lower right): the base line AB, bisected at C
- (gnomon LM and parallelograms AG, DG, CE, FK as described in the text)

But if the point G is taken on the diameter BD extended beyond the parallelogram CE, then, drawing through G the line HM parallel to AB (meeting the lines AK and BE, extended, at H and M) and likewise drawing GF parallel to AH, the parallelogram AG will be applied along AB, deficient by the parallelogram FM, [Margin: g — *Elements* VI.4] which is similar and similarly situated to CE, since it

lies about the same diameter as CE. I say that AD is still greater than AG. For, CD being extended to L, the lines HL and LM will be equal, [Margin: h — *Elements* I.34] since they are equal to the equals AC and CB; [Margin: i — *Elements* I.36] and therefore the parallelograms HD and DM are equal. [Margin: k — *Elements* I.43] Since, then, DM is equal to the complement DF, HD too will be equal to DF. But HD is greater than HI by the parallelogram IL. Therefore DF too is greater than HI by that same parallelogram IL. And accordingly, when the common AI is added, AD will be greater than AG by that same parallelogram IL. By the same arguments you will conclude that AD is greater than any parallelogram so applied along the line AB that the point G lies beyond D on the diameter BD extended — that is, one that occupies a line less than the half AC and has a greater height than AD — provided its defect is similar to the parallelogram CE. And so, of all parallelograms applied to the same straight line, and so on. Which was to be demonstrated.

Diagram. The figure for the case in which G falls beyond D on the extended diameter. The applied parallelogram AG is deficient by FM.

- H (upper left), G (upper), L (upper), M (upper right): top edge, with HM parallel to AB
- K (left), I (interior left), D (centre), E (right): middle line
- A (lower left), F (lower), C (lower middle), B (lower right): the base line AB

Euclid, *Elements*, Book VI (Clavius's commentary)

Scholium (to Proposition 27, continued)

Moreover, it is clear that the line to which the deficient parallelogram is applied is either greater than the half AC — as AK is, in the former figure — or less than it — as AF is, in the latter figure — according as the point G is taken either on the diameter BD or on its extension toward D.

PROBL. 8. PROPOS. 28.

[Margin: xxvii.]

To a given straight line to apply a parallelogram equal to a given rectilinear figure and deficient by a parallelogrammic figure that is similar to another given parallelogram. But the given rectilinear figure, to which the parallelogram to be applied is to be equal, must not be greater than the parallelogram that is applied to the half of the line,

when the defects are similar — that is, not greater than both the parallelogram applied to the half and the parallelogram to which the defect must be similar.

Demonstration. Let it be required to apply to the given straight line AB a parallelogram equal to the given rectilinear figure C and deficient by a parallelogram similar to the other given parallelogram D. Bisect AB at E, and [Margin: a — *Elements* VI.18] on the half EB describe the parallelogram EFGB similar to D and similarly placed; then complete the whole parallelogram AHGB. Now if AF is equal to C, then — since it has been applied to AB, deficient by the parallelogram EG similar to D — what is required is done.

But suppose AF is greater than C. (It cannot be less: for since, by the preceding proposition, AF is the greatest of all figures applied to the half — provided the defects are similar — no figure equal to C could be applied to AB, but all would be smaller. This is why Euclid added the clause, "but the given rectilinear figure must not be greater," etc.) Then EG, being equal to AF, will likewise be greater than C. Let it exceed by the rectilinear figure I. (How the excess of two rectilinear figures is to be found, we taught at Proposition 45 of Book 1.) [Margin: b — *Elements* VI.25] Now construct the parallelogram KLMN, similar and similarly placed to D (that is, to EG), but equal to the excess I that was found; so that EG is equal to the rectilinear figure C together with the parallelogram KM, and on that account greater than KM.

Since, then, by the similarity, EF is to FG as NK is to KL, the sides EF, FG will also be greater than the sides NK, KL. For if these were equal to or less than those, EG too would be equal to or less than NL, as is evident. Therefore cut off the straight lines FO, FQ equal to KN, KL, and complete the parallelogram FQPO; this will be equal to LN, and similar and similarly placed to it, and therefore to EG as well. [Margin: c — *Elements* VI.26] And so it will lie about the same diameter as EG — namely BF. Then, when the straight lines QP, OP have been produced, [Margin: d — *Elements* VI.24] the parallelogram AP, applied to the straight line AB and deficient by the parallelogram PB, will be the figure sought — for PB is similar to EG and similarly placed, and therefore similar to D.

I say, then, that AP is equal to the rectilinear figure C. [Margin: e — *Elements* I.43] For since PG is equal to the complement PE, if the common PE is added, BQ will be equal to ER — that is, to ES [?] — [Margin: f — *Elements* I.36] because the bases EA, EB are equal. Therefore, if the common EP is added to the equals AO, BQ, AP will become equal to the gnomon TV. But the gnomon TV is equal to the rectilinear figure C. (For since EG is equal to the figure C together with LN, if the

equals QO, LN are taken away, the gnomon TV will remain equal to C.) Therefore AP too will be equal to C. To the given straight line AB, then, has been applied the parallelogram AP, deficient by the parallelogram PB — which is similar to the given parallelogram D — and equal to the given rectilinear figure C. Which was to be done.

Diagram. The construction for Proposition 28 (application of a parallelogram deficient by one similar to a given figure). At upper left stand two auxiliary triangles — the larger labelled **C** and a smaller one at the right labelled **I** — together with a small quadrilateral labelled **D** (the given parallelogram). Below these is the main figure: a large parallelogram/gnomon construction on the base AB. Readable vertex-labels:

- H, F, Q, G (top edge, left to right)
- K, L (short bracketed segment at the right, marking KL / the constructed parallelogram KLMN)
- S, O, V, P, R (interior/middle line; a semicircular arc is drawn about the region near P–R)
- A, F, B, N, M (base edge, left to right)

The diagonal runs from the upper-left toward B (the common diameter BF); the gnomon TV and complements referred to in the text occupy the interior. Several interior and peripheral labels sit at the resolution floor; the reused letter F at both top and base could not be disambiguated with full confidence. (more than two labels uncertain).

Scholium (to Proposition 28)

Jacobus Peletarius [Jacques Peletier] and Nicolaus Tartalea [Niccolò Tartaglia] raise a certain doubt at this point, which has no place in our construction, since upon EB we set up EG as a parallelogram not only similar to D but also similarly placed — which they did not do. On this matter, if you wish, consult their commentaries.

It is also clear that if a parallelogram deficient by a square is applied to a straight line, the applied figure is equal to the rectangle contained by the segments of the line made by the application. Thus, if AC is applied to AB, deficient by the square CB, the applied figure AC will be the rectangle contained by AD and DC. Since, then, DC is equal to DB — because of the square CB — AC will likewise be contained by the segments AD, DB made by the application. Which is what was proposed.

Diagram. A small rectangle illustrating the note on a parallelogram deficient by a square. The base carries the points **A** (bottom left), **D** (midpoint), **B** (bottom right); a vertical line rises from **D** to the point **C** at the top edge, dividing the rectangle into the applied rectangle **AC** (left) and the square **CB** (right).

PROBL. 9. PROPOS. 29.

[Margin: xxviii.]

To a given straight line to apply a parallelogram equal to a given rectilinear figure and exceeding by a parallelogrammic figure that is similar to another given parallelogram.

Demonstration. Let it be required to apply to the given straight line **AB** a parallelogram equal to the given rectilinear figure **C** and exceeding by a parallelogram similar to the other given parallelogram **D**. Bisect **AB** at **E**; [Margin: a — *Elements* VI.18] on the half **EB** construct the parallelogram **EFGB** similar to **D** and similarly placed. [Margin: b — *Elements* II.14] Next construct a square **H** equal to the rectilinear figure **C** and the parallelogram **EG** together; [Margin: c — *Elements* VI.25] and let there be made a parallelogram **IKLM** equal to that square, but similar to **EG** and similarly placed. **IKLM** will therefore be greater than **EFGB**, since it is equal to the rectilinear figure **C** together with the parallelogram **EG**.

Since, then, on account of the similarity of **MK** and **EG**, **MI** is to **IK** as **EF** is to **FG**, the sides **MI**, **IK** will also be greater than the sides **EF**, **FG**. For if those were equal to or less than these, **MK** would likewise be equal to or less than **EG**, as is plain. Therefore produce **FE**, **FG** so that the straight lines **FO**, **FN** are equal to **IM**, **IK**, and complete the parallelogram **ON**; [Margin: d — *Elements* VI.26] this will be similar and similarly placed to **EG**, since it is equal, similar, and similarly placed to **MK**. Consequently **ON** and **EG** lie about the same diameter — let it be **FP**.

Now produce **AB**, **GB** to **Q** and **R**, and **PO**, until it meets **AS** (which is parallel to **FO**) at **S**; then the parallelogram **AP**, applied to the straight line **AB** and exceeding by the parallelogram **QR**, [Margin: c — *Elements* VI.24] is the figure sought — for **QR** is similar to **EG** and therefore to **D**. I say, then, that **AP** is equal to the rectilinear figure **C**. [Margin: f — *Elements* I.36] For since **AO** and **ER** are equal, [Margin: g — *Elements* I.43] and **ER** is equal to the complement **BN**, **AO** too will be equal to **BN**. Adding, then, the common **OQ**, **AP** becomes equal to the gnomon **EPG**. But the gnomon **EPG** is equal to the rectilinear figure **C**. (For since **MK** — that is, **ON** — is equal to the rectilinear figure **C** together with **EG**, if the common **EG** is taken away, the gnomon **EPG** and the rectilinear figure **C** will remain equal.) Therefore

AP too will be equal to the rectilinear figure C. To the given straight line AB, then, has been applied a parallelogram AP equal to the given rectilinear figure C and exceeding by the parallelogram RQ, which is similar to the other given figure D. Which was to be done.

Diagram. The construction for Proposition 29 (application of a parallelogram exceeding by one similar to a given figure). At the left is a square labelled **H** (the constructed square equal to C plus EG); to its right a large parallelogram/gnomon construction with an inscribed diagonal and a semicircular arc. Below-left is a small quadrilateral labelled **D** (the given parallelogram). Readable vertex-labels:

- K, L (top-left region of the parallelogram IKLM)
- I, M (its lower vertices)
- N, G, Q (upper edge, right portion)
- B, P (with a doubled P near the arc and the point B), F, E, O, A (base and interior)

The gnomon EPG and complements named in the proof occupy the interior. Several peripheral labels are at the resolution floor. (more than two labels uncertain).

PROBL. 10. PROPOS. 30.

[Margin: xxix.]

To cut a given finite straight line in extreme and mean ratio.

Demonstration. Let AB be the straight line to be cut in extreme and mean ratio. Describe the square ABC upon it; [Margin: a — *Elements* VI.29] and to the side DA apply the rectangle DF, equal to the square AC and exceeding by a parallelogram AF similar to the square — so that AF too is a square, since only a square is similar to a square. Let the straight line EF cut the straight line AB at H. I say that AB is cut at H in extreme and mean ratio.

For since DF and AC are equal, if the common AE is taken away, the remainders GH, HC will be equal. And since these have equal angles AHF, BHE — right angles, that is — [Margin: b — *Elements* VI.14] the sides about those angles will be reciprocally proportional; that is, EH — that is, AB [?], equal to EH — will be to HF (that is, to AH, equal to HF) as AH is to HB. Therefore, since the whole AB is to the segment AH as the segment AH is to the segment HB, AB has been cut in extreme and mean ratio, by definition. So the given finite straight line, etc. Which was to be done.

Otherwise. We shall also show that AB is cut at H in extreme and mean ratio thus. Since three lines are given — AB, AH, HB — and the rectangle HC, contained by the first AB and the third HB, is equal to the square on the mean AH, [Margin: c — *Elements* VI.17] these will be proportional: as AB, the first, is to AH, the second, so AH, the second, is to HB, the third. Therefore, by the definition, AB has been cut at H in extreme and mean ratio.

Otherwise. We shall carry out the whole problem in another way. [Margin: d — *Elements* II.11] Let AB be divided at C in such a way that the rectangle contained by the whole AB and the segment CB is equal to the square on the other segment AC. I say that AB is cut at C in extreme and mean ratio. [Margin: e — *Elements* VI.17] For here again the three lines AB, AC, CB will be continuously proportional. So the proposition stands.

Diagram. The figure for Proposition 30 (cutting a line in extreme and mean ratio): a large square standing on the base AB with an applied rectangle. Readable labels along the base are **D** (bottom left), **A** (bottom middle), **C** (bottom right); along the top **G** [?] (top left) and **B** (top right); and in the middle band **E**, **H**, **F** [?] (left to right). The square ABC and the rectangles GH, HC named in the proof are formed by the horizontal EH-line and the vertical through H. Two labels are at the resolution floor.

Diagram. A single straight segment for the second "Otherwise": the line **A**——**C**——**B**, marked with a division point (C) between A and B.

Scholium (to Proposition 30)

The practical construction for dividing a straight line in extreme and mean ratio is to be carried out as we set forth at Proposition 11 of Book 2. Moreover, this section of a line in extreme and mean ratio has remarkable uses and properties, as will be evident in the books of Stereometry — so much so that, not without reason, a line so divided is said by very many mathematicians to have, in a manner of speaking, a "divine" proportion, on account of its wonderful power and nature; while others simply call it a "line divided proportionally."

THEOR. 21. PROPOS. 31.

In right-angled triangles, the figure described on the side subtending the right angle is equal to the figures, similar and similarly placed, described on the sides containing the right angle.

Demonstration. Let ABC be a right-angled triangle having the angle BAC a right angle; and on BC let there be described [Margin: a — *Elements* VI.18] any rectilinear figure BCDE, and on AB, AC let figures ABFG, ACIH be set up similar and similarly placed to it. I say that the figure BD is equal to the two figures AF, AI together.

For drop from A the perpendicular AK to BC; then, by the corollary to Proposition 8 of this book, BC is to CA as CA is to CK. Therefore, as BC is to CK (the first line to the third), so is the figure BD on the first to the figure CH on the second, similar and similarly placed, by the corollary to Proposition 19 or 20 of this book. And, converting, as CK is to BC, so is the figure CH to the figure BD. In the same way it will be shown that, as BK is to BC, so is the figure BG to the figure BD — since the three lines BC, BA, BK are likewise proportional, etc.

Now since CK, the first magnitude, is to BC, the second, as CH, the third, is to BD, the fourth; and likewise BK, the fifth magnitude, is to BC, the second, as BG, the sixth, is to BD, the fourth — [Margin: b — *Elements* V.24] it follows that the first CK together with the fifth BK is to the second BC as the third CH together with the sixth BG is to the fourth BD. But CK and BK, the first and fifth together, are equal to the second BC. Therefore CH and BG, the third and sixth together, will also be equal to the fourth BD. Which is the proposition.

Otherwise. [Margin: c — *Elements* VI.8] Since the triangle KAC is similar to the triangle ABC, and their corresponding sides are BC, CA [Margin: d — *Elements* VI.19] (for as BC is to CA in triangle ABC, so is CA to CK in triangle KAC), the triangle KAC will have to the triangle ABC the duplicate ratio of that which CA has to BC. [Margin: e — *Elements* VI.19 or 20] But the figure CH also has to the figure BD the duplicate ratio of CA to BC. [Margin: f — *Elements* V.11] Therefore, as the triangle KAC is to the triangle ABC, so is the figure CH to the figure BD. By the same reasoning it will be shown that, as the triangle KBA is to the triangle ABC, so is the figure BG to the figure BD.

Since, then, again KAC, the first magnitude, is to ABC, the second, as CH, the third, is to BD, the fourth; and likewise KBA, the fifth, is to ABC, the second, as BG, the sixth, is to BD, the fourth — [Margin: g — *Elements* V.24] the first KAC composed with the fifth KBA will be to the second ABC as the third CH composed with the sixth BG is to the fourth BD. But KAC, KBA, the first and fifth together, are equal to the second ABC. Therefore CH, BG, the third and sixth together, will also be equal to the fourth BD. Which is the proposition.

Otherwise. As the square on the line AC, the first magnitude, is to the square on BC, the second, so is the figure CH, the third magnitude, to the figure BD, the fourth — [Margin: i — *Elements* VI.19 or 20] since each pair is in the duplicate ratio of AC to BC. Similarly, as the square on the line AB is to the square on BC, the second magnitude, so is the figure BG, the sixth, to the figure BD. [Margin: i — *Elements* V.24] Wherefore, as the first magnitude together with the fifth — namely the square on AC together with the square on AB — is to the second, that is, to the square on BC, so is the third magnitude together with the sixth — namely the figure CH together with BG — to the fourth, namely to the figure BD. [Margin: k — *Elements* I.47] But the squares on the lines AC, AB together are equal to the square on the line BC. Therefore the figures CH, BG will also be equal to the figure BD. Which is the proposition. So, in right-angled triangles, any figure, etc. Which was to be demonstrated.

Diagram. The figure for Proposition 31 (the generalized Pythagorean theorem): the right triangle ABC with a figure erected on each side. Readable vertex-labels:

- A (apex of the right angle at the top center)
- H (top, above the figure on AC)
- G (upper left, on the figure over AB)
- F (left), B (lower left) — corners of the figure ABFG on side AB
- K (foot of the perpendicular AK on BC), Q (lower right, at vertex C of the base figure) — [the base vertex read as C/Q]
- E (bottom left), D (bottom right) — the figure BCDE on the hypotenuse BC
- I (right, on the figure over AC)

The perpendicular AK falls from A to BC. (*The same construction appears in partial view at the foot of p. 293, where only the labels F, B, E of its left portion are legible.*)

Scholium (to Proposition 31)

You see, then, that this theorem of Euclid's is far more general — since it extends to all similar and similarly described figures — than that discovery of Pythagoras, which embraces squares alone, as we noted at Proposition 47 of Book 1. Yet that theorem, the one we there demonstrated from Pappus, seems in some respect still more general than this one, since it is propounded for every triangle and for parallelograms even when not similar, whereas this one is propounded only for a right-angled triangle and for figures that are similar and similarly placed.

We shall also convert this theorem, following Campanus, in just the same way as the 47th proposition of Book 1, as follows.

If the figure described on one of the sides of a triangle is equal to those described on the remaining sides of the triangle — the figures being similar and similarly placed — then the angle contained by the remaining two sides of the triangle is a right angle.

Let a triangle ABC be given, and let any figure described on the side BC be equal to two figures, similar to it and similarly described, on the remaining sides AB, AC. I say that the angle BAC is a right angle. For draw AD perpendicular to AC, equal to AB, and join the straight line CD. Now since the angle CAD is a right angle, [Margin: l — Elements VI.31] the figure described on CD (similar to the one on BC and similarly placed) will be equal to the figures described on AD, AC that are similar to it and similarly placed. But the figure on AD is equal to the figure on AB, because the sides are equal. Therefore the figure on CD will be equal to the figures on AB, AC together. And since the figure on BC is assumed equal to those same figures on AB, AC, the figures on CD and BC will be equal to one another; and therefore the straight lines CD, BC will be equal, as is clear from the lemma to Proposition 22 of this book. Since, then, the sides AC, AD of triangle ADC are equal to the sides AB, AC of triangle ABC, and the base DC has been shown equal to the base BC, [Margin: m — Elements I.8] the angles DAC, BAC will be equal. Therefore, since DAC is a right angle by construction, BAC will also be a right angle. Which is the proposition.

Diagram. The figure for the converse (Campanus's conversion): a triangle with vertices **D** (top), **A** (upper left, interior/apex region), **B** (lower left), and **C/Q** (lower right) — the constructed perpendicular AD and the joined line CD forming triangle ADC alongside the original triangle ABC.

THEOR. 22. PROPOS. 32.

[Margin: xxx.]

If two triangles that have two sides proportional to two sides be set together at a single angle so that their corresponding sides are also parallel, then the remaining sides of those triangles will be found to lie in a straight line.

Demonstration. Let the triangles ABC, DCE have the sides AB, AC proportional to the sides DC, DE — namely, as AB is to AC, so DC is to DE — and let them be set together at the angle ACD so that the corresponding sides AB, DC, and likewise AC,

DE, are parallel to one another. I say that the two remaining sides BC, CE form a straight line.

For since AB, DC are parallel, [Margin: a — *Elements* I.29] the angle A will be equal to the alternate angle ACD; and for the same reason the angle D will be equal to that same angle ACD; and therefore A and D will also be equal to one another. Now since the triangles ABC, DCE have the sides about the equal angles A, D proportional, [Margin: b — *Elements* VI.6] they will be equiangular with one another and will have the angles B, DCE equal. Therefore, adding the equals A and ACD, the two angles B, A will be equal to the two angles DCE, ACD — that is, to the angle ACE. Again, adding the common angle ACB, the three angles of the triangle ABC will become equal to the two angles ACE, ACB; [Margin: c — *Elements* I.32] but those three are equal to two right angles. Therefore the two angles ACE, ACB will also be equal to two right angles; [Margin: d — *Elements* I.14] and for that reason BC, CE will constitute one straight line. And so, if two triangles that have two sides proportional to two sides, etc. Which was to be demonstrated.

Diagram. The figure for Proposition 32: two triangles set together along the base line. The larger triangle **ABC** has apex **A** (top), base vertices **B** (bottom left) and **C** (bottom middle); the smaller triangle **DCE** has apex **D** (upper right), sharing the vertex region at **C** and reaching **E** (bottom right). The base runs B — C — E in a single straight line.

SCHOLIUM

(Continuation of the scholium to Prop. 32.)

The two aforesaid triangles must be joined at one angle in such a way that each of the angles contained by the proportional sides is *alternate* to the angle at which the triangles are joined — as you see done in the figure of the theorem. For to the angle ACD, at which the triangles are joined, both angle A and angle D are alternate, and each of these is contained by proportional sides. From this it follows that angles A and D are equal, and therefore that the triangles are equiangular; and thus BC and CE form a single straight line, as is clear from the demonstration.

But if each of the angles contained by the proportional sides is *not* alternate to the angle at which the triangles are joined, then — even though the remaining hypotheses of the theorem are preserved — the conclusion does not necessarily follow. For the two triangles ABC and DBE have two sides AB, AC proportional to the two sides DE, DB (namely, as AB is to AC, so is DE to DB), and they are joined

at the angle CBD, so that the corresponding sides AB, DE, as well as AC, DB, are parallel. Nevertheless the remaining two sides CB, BE do *not* form a single straight line, because neither of the angles A and D is alternate to the angle CBD — indeed, neither of them is, as is evident. For this reason the demonstration of the theorem has no place here.

Diagram. The counterexample figure for the scholium: two triangles joined at the vertex B, showing that the remaining sides do not lie in one straight line when the alternate-angle condition fails.

- C (top): apex of the upper triangle
- D (right, below C): apex of the second triangle
- A (upper left): apex of triangle ABC
- B (lower left): the common joining vertex
- E (lower middle/right): far endpoint of side BE
- Straight lines are drawn from B to A, C, D, and E; the triangles ABC and DBE share the vertex B, and sides CB, BE visibly fail to be collinear.

THEOR. 23. PROPOS. 33.

[Margin: xxxij. — proposition number in the outer margin; the middle glyph is ambiguous between *i* and *l*, read here as *xxxij* (32), lagging the body number 33 by one[?]]

In equal circles, the angles have the same ratio as the arcs on which they stand, whether they are constructed at the centres or at the circumferences. Moreover, the sectors do likewise, since they stand at the centres.

Let there be two equal circles ABC, EFG, whose centres are D and H; and let any two arcs whatever, BC and FG, be taken from the circles, on which stand the angles BDC, FHG at the centres, and the angles BAC, EFG at the circumferences. I say that — by the sense of definition 6 of Book 5 — as the arc BC is to the arc FG, so is the angle BDC to the angle FHG, and the angle BAC to the angle FEG; and moreover that the sector BDC, which is contained by the straight lines BD, DC and the arc BC, is to the sector FHG, which the straight lines FH, HG and the arc FG comprehend, in the same ratio.

For draw the straight lines BC, FG, and [Margin: a — *Elements* IV.1] apply to them, within the circles, equal straight lines: CI equal to BC, and GK, KL equal to FG; and draw the straight lines ID, KH, LH. Since, then, the straight lines BC, CI are equal,

[Margin: b — III.28] the arcs BC, CI will also be equal, [Margin: c — III.27] and therefore the angles BDC, CDI will be equal too. By the same reasoning the arcs FG, GK, KL will be equal, and so will the angles FHG, GHK, KHL.

Therefore, whatever multiple the arc BCI is of the arc BC, the angle BDI — that is, the aggregate of the angles near the centre D standing on the arc BCI — is the same multiple of the angle BDC; and whatever multiple the arc FGKL is of the arc FG, the angle FHL is the same multiple of the angle FHG, since the angles BDI, FHL are divided into just as many equal angles as the arcs BCI, FGKL are cut into equal arcs. And since, if the arc BCI is equal to the arc FGKL, [Margin: d — III.27] the angle BDI is necessarily equal to the angle FHL; if the arc BCI is greater than the arc FGKL, the angle BDI is necessarily greater than the angle FHL; and if less, less: therefore the arc BCI and the angle BDI — equimultiples of the first magnitude BC and the third BDC — will, together with the arc FGKL and the angle FHL — equimultiples of the second magnitude FG and the fourth FHG — either together fall short, or together be equal, or together exceed, if those are taken that correspond to one another. [Margin: e — V def. 6] Hence, as the arc BC, the first magnitude, is to the arc FG, the second magnitude, so will the angle BDC, the third magnitude, be to the angle FHG, the fourth magnitude.

Diagram. Two equal circles for the proof of Prop. 33: a left circle with centre D and a right circle with centre H, in each of which equal arcs are stepped off from a common chord and radii are drawn to the circumference, together with the inscribed (circumference) angles. Several small peripheral vertex-letters sit at the resolution floor.

- D (centre, left circle): centre
- A (top of left circle): vertex of the circumference angle BAC
- B (lower left of left circle): endpoint of the base chord
- C (lower right of left circle): common endpoint of the equal arcs BC, CI
- I (upper right of left circle): far endpoint of the stepped-off equal arc CI
- M (bottom of left circle): peripheral point (role at the resolution floor) [?]
- N (interior, right of D): labelled point on/near a radius [?]
- H (centre, right circle): centre
- Top vertex of right circle (the circumference-angle vertex, expected E) [?]
- F, G (lower left / lower right of right circle): endpoints of the base arc FG
- K (upper right of right circle): stepped-off equal-arc point
- L (right of right circle): far endpoint of the stepped-off equal arcs [?]

- Radii DB, DC, DI and HF, HG, HK, HL are drawn, with chords BC, CI and FG, GK, KL.

And this is likewise true of the *regions* [spatia] about the centres — that is, as the arc BAC is to the arc FEG, so is the region at the centre D standing on the arc BAC to the region at the centre H standing on the arc FEG. For these regions too, if they are equal, stand on equal arcs, and if unequal, on unequal arcs, and so on.

Now, since [Margin: f — V.15] as the angle BDC is to the angle FHG, so is the angle BAC to the angle FEG — [Margin: g — III.20] because the former of each pair is the double of the latter — it is evident [Margin: h — V.11] that the angle BAC is likewise to the angle FEG as the arc BC is to the arc FG. This, however, can be demonstrated by the same arguments we used for the angles constructed at the centres, provided the straight lines IA, KE, LE, and so on, are first drawn.

But if angles of this kind, BAC, FEG, are constructed at the circumferences in such a way that the straight lines drawn BD, CD, FH, GH do not form angles at the centres facing the arcs BMC, FG, then one must take the regions BDC, FHG, which are likewise double the angles at the circumferences, by the scholium to Prop. 20 of Book 3.

Now let there be constructed, in the segments BC, CI, the angles BMC, CNI, [Margin: i — III.27] which will be equal, since they stand on the equal arcs BAC, CBAI. Therefore the segments BMC, CNI will be similar, [Margin: k — III.24] and moreover equal to one another, because they stand on the equal straight lines BC, CI. Adding, then, the triangles BDC, CDI, [Margin: l — I.4] which are likewise equal, the sectors BDC, CDI become equal. Hence the sector BDI is the same multiple of the sector BDC as the arc BCI is of the arc BC. In the same way we shall show that the sector FHL is the same multiple of the sector FHG as the arc FGKL is of the arc FG. And since, if the arc BCI is equal to the arc FGKL, the sector BDI is also equal to the sector FHL — as was shown for the sectors BDC, CDI — and if greater, greater, and if less,

less: therefore the arc BCI and the sector BDI — equimultiples of the first magnitude BC and the third BDC — will, together with the arc FGKL and the sector FHL — equimultiples of the second magnitude FG and the fourth FHG — either together fall short, or together be equal, or together exceed, if those are taken that correspond to one another. [Margin: i — V def. 6] Therefore, as the arc BC, the first magnitude, is to the arc FG, the second magnitude, so will the sector BDC, the third magnitude, be to the sector FHG, the fourth magnitude. Therefore,

in equal circles, the angles have the same ratio as the arcs, and so on. Which was to be demonstrated.

Perhaps the demonstration will be set up more conveniently in this way. Take (at least in thought) any number of circles equal to the circle ABC, and in each of them mark off a single arc equal to the arc BC, on which stand angles both at the centres and at the circumferences. For all these angles will be equal to the angles BDC, BAC, because of the equality of the arcs on which they stand; and consequently their aggregates will be the same multiples of the angles BDC, BAC as the aggregate of all the arcs is of the arc BC. Then take likewise any number of circles equal to the circle EFG, and in each mark off a single arc equal to the arc FG, and so on. For in this way one avoids the confusion of lines and angles within the circles ABC, EFG — a confusion that necessarily arises when the arcs BC, FG are large and their multiples have to be taken, as is evident. For if the arcs were BCI, FGL, on which stand the angles BDI, FHL at the centres and BAI, FEL at the circumferences, their multiples could not be taken without confusion, as is plain. But this confusion is avoided if several equal circles are employed, as we have said.

COROLLARY I

From this it is evident that the sector is to the sector as the angle is to the angle. For each of the two ratios is equal to the ratio of the arc to the arc; [Margin: k — V.11] therefore they will also be equal to one another.

COROLLARY II

It is likewise evident that, as an angle at the centre is to four right angles, so is the arc subtended by that angle to the whole circumference; and conversely, as four right angles are to the angle at the centre, so is the whole circumference to the arc subtended by that angle.

For as an angle at the centre is to a right angle at the centre, [Margin: l — VI.33] so is the arc subtended by that angle to the quadrant subtended by the right angle. Hence, as the angle at the centre is to the quadruple of the right angle — that is, to four right angles — so will the arc subtended by that angle be to the quadruple of the quadrant — namely, to the whole circumference — by what we demonstrated at Prop. 22 of Book 5. This is the first point. Since, then, as the angle at the centre is to four right angles, so is the arc subtended by that angle to the whole circumference, it will also follow, by conversion, that as four right angles are to the angle at the centre, so is the whole circumference to the arc subtended by the angle at the centre. This is the second point.

But this will also be demonstrated in the following way. [Margin: m — VI.33]
Since, as a right angle at the centre is to the angle at the centre, so is the quadrant subtended by the right angle to the arc subtended by that angle, it will also follow — by what we showed at Prop. 22 of Book 5 — that as the quadruple of the right angle, namely four right angles, is to the angle at the centre, so is the quadruple of the quadrant — namely, the whole circumference — to the arc subtended by that angle. Which was proposed.

The same is true of the region [spatium] at the centre: that is, as the region at the centre is to four right angles, so is the arc subtended by that region to the whole circumference, and so on, as is clear from the demonstration.

SCHOLIUM

Moreover, from this theorem it is gathered, more clearly than daylight, that an angle standing on some arc must be referred to the arc that is the *base* of the angle, and not to the arc *in which it lies*. For the ratio of angle to angle is not the same as that of arc to arc if one takes the arcs in which the angles lie, as Euclid intends in the present theorem. For let there be equal circles ABC, DEF, in which the inscribed angles B, E are constructed, B being the greater and E the lesser. On this supposition, the arc AC will be greater than the arc DF, by the scholium to Prop. 26 of Book 3, and therefore the remaining arc ABC will be less than the remaining arc DEF. Hence the ratio of angle B to angle E is one of greater inequality, whereas the ratio of arc ABC to arc DEF is one of lesser inequality. Therefore the ratio of angle to angle is not the same as the ratio of arc to arc. But if we take the arcs on which the angles stand — namely, the arcs AC, DF — then at last angle B will be to angle E as arc AC is to arc DF, as Euclid rightly demonstrated. And so, when we say an angle *is in* a segment, we must understand something different from when we say an angle *stands on* a segment or arc. This we pointed out in the exposition of definition 8 of Book 3.

Diagram. Two equal circles illustrating the scholium: in each, an inscribed angle stands on a chord, the angle at B being greater than the angle at E.

- B (top of left circle): vertex of the inscribed angle, standing on chord AC
- A (lower left of left circle): endpoint of the base chord AC
- C (lower right of left circle): endpoint of the base chord AC
- E (top of right circle): vertex of the inscribed angle, standing on chord DF
- D (lower left of right circle): endpoint of the base chord DF
- F (lower right of right circle): endpoint of the base chord DF

It can also be demonstrated, and not obscurely, from this theorem, that the similarity of segments in similar circles — which Euclid, in definition 10 of Book 3, defined by means of the equal angles existing within those segments — consists in this: that the segments, or the similar arcs, have the same ratio to the whole circumferences of the circles; and therefore, when the segments are commensurable with the whole circles, whatever part one arc is of its whole circumference, such a part likewise is the other similar arc of its whole circumference — as we taught in the exposition of the aforesaid definition. For let there first be two equal circles ABC, DEF, in which equal angles BAC, EDF are constructed at the circumferences. On this supposition, the segments BAC, EDF will be called similar, according to Euclid's aforesaid definition. Now it is evident that their arcs have the same ratio to the whole circumferences of the circles. For since, because of the equality of the circles, [Margin: n — III.28] the arcs BC, EF, on which the equal angles stand, are equal, it follows that the remaining arcs BAC, EDF are also equal. Therefore, in relation to the whole circumferences — which are also assumed equal — [Margin: o — V.7] they will have the same ratio; and accordingly, whatever part the arc BAC is of the whole circumference ABCA, the same part will the arc EDF be of the whole circumference DEFD.

Diagram. Two equal circles, each with an inscribed triangle, illustrating similar segments defined by equal inscribed angles.

- A (top of left circle): vertex of the inscribed angle BAC
- B (lower left of left circle): base vertex
- C (lower right of left circle): base vertex
- D (top of right circle): vertex of the inscribed angle EDF
- E (lower left of right circle): base vertex
- F (lower right of right circle): base vertex

Next, let there be two *unequal* circles ABC, DEF, in which equal angles BAC, EDF are constructed at the circumferences. On this supposition, the segments BAC, EDF will be called similar, according to Euclid's view. I say again that the arcs BAC, EDF have the same ratio to their whole circumferences. For draw to the centres G, H the straight lines BG, CG, EH, FH. Since, then, the angles A and D are assumed equal, the angles G and H at the centres will also be equal, [Margin: p — III.20] since these are the doubles of those; or else the regions [spatia] at the centres will be equal, since these too are double the angles at the circumferences, by the scholium to Prop. 20 of Book 3. [Margin: q — V.7] Therefore four right angles will have the same ratio to the angle (or region) G as to the angle (or region) H. But as four right angles are to the angle or region G, so is the whole

circumference ABCA to the arc BC; and as four right angles are to the angle or region H, so is the whole circumference DEFD to the arc EF, by Corollary 2 of this Proposition 33. [Margin: r — V.11] Therefore, as the whole circumference ABCA is to the arc BC, so will the whole circumference DEFD be to the arc EF. Hence, by conversion of the ratio, it will also follow that as the whole circumference ABCA is to the arc BAC, so is the whole circumference DEFD to the arc EDF. And, inverting, as the arc BAC is to the whole circumference ABCA, so is the arc EDF to the whole circumference DEFD. And so, whatever part the arc BAC is of the whole circumference ABCA, the same part will the arc EDF be of the whole circumference DEFD. Which was proposed.

Diagram. Two *unequal* circles, each with an inscribed triangle and radii drawn to the centre, illustrating similar segments in unequal circles.

- A (top of left circle): vertex of the inscribed angle
- G (centre of left circle): centre, with radii GB, GC drawn
- B (lower left of left circle): base vertex
- C (lower right of left circle): base vertex
- D (top of right circle): vertex of the inscribed angle
- H (centre of right circle): centre, with radii HE, HF drawn
- E (lower left of right circle): base vertex
- F (lower right of right circle): base vertex

It is therefore established that Euclid rightly called those segments of circles *similar* in which the angles existing are equal to one another, since segments of this kind have the same ratio to their whole circles.

From these results that theorem will easily be demonstrated which we showed, without proportions, both at the end of chapter 1 on the sphere and at Prop. 22 of Book 3 — namely:

If two or more circles are described about the same centre, and from the centre two or more straight lines are drawn, the arcs intercepted between any two of the lines will be similar.

Let two circles ABCD, EFGH be described about the same centre I. If, then, two straight lines IB, ID go out from the centre I forming a single straight line BD, it is evident that the arcs BAD, FEH are similar, since they are semicircles. Again, if two straight lines IA, ID go out from I forming the right angle AID, it is likewise clear that the arcs AD, EH are similar, since — by the scholium to Prop. 27 of Book 3 — they are quadrants of their circles. Now let two straight lines ID, IK be drawn

from I, making any non-right angle DIK. I say that even so the arcs DK, HL are similar — that is, that the arc DK is to the whole circumference ABCD as the arc HL is to the whole circumference EFGH. For since, as the angle DIK is to four right angles, so — by the corollary of this proposition — is both the arc DK to the whole circumference ABCD and the arc HL to the whole circumference EFGH, [Margin: s — V.11] it will follow that as the arc DK is to the whole circumference ABCD, so is the arc HL to the whole circumference EFGH; and therefore the arcs DK, HL will be similar. Which was proposed.

Diagram. Two concentric circles about the common centre I: the outer circle ABCD and the inner circle EFGH, with two diameters and the radii ID, IK cutting off the arcs DK (outer) and HL (inner).

- I (centre): common centre
- A (top, outer circle); E (top, inner circle, on radius IA)
- B (left, outer circle); F (left, inner circle, on radius IB)
- C (bottom, outer circle); G (bottom, inner circle)
- D (right, outer circle); H (right, inner circle, on the horizontal diameter)
- K (upper right, outer circle): endpoint of the oblique radius IK
- L (upper right, inner circle, on radius IK): where the oblique radius meets the inner circle

The same will be confirmed more briefly in this way. Since on the arcs DK, HL there stand, at the centre I, equal angles — indeed the very same angle — the arcs DK, HL are similar, by the scholium to Prop. 22 of Book 3; and consequently they will have the same ratio to the whole circumferences, as was shown a little earlier.

By the same reasoning we shall show that the arcs BAK, FEL are similar — that is, that they have the same ratio to the whole circumferences.

But it is fitting to demonstrate here also the lemma that we set forth at Prop. 6 of Book 3 of Theodosius, since it is useful for many other purposes. It runs as follows.

Equal straight lines cut off unequal arcs from unequal circles, and the arc of the smaller circle is greater than would make it similar to the arc of the larger circle.

Let there be unequal circles AB, CD described about the same centre E. Draw from E two arbitrary straight lines EA, EB, cutting the circles at the points A, B and C, D; the arcs AB, CD will be similar, as we demonstrated just now. And since

the straight lines EA, EB are cut proportionally at C, D — because EA, EB are equal to one another — [Margin: t — VI.2] the drawn straight lines AB, CD will be parallel; and therefore the triangles EAB, ECD will be similar, by the corollary to Prop. 4 of this book. [Margin: u — VI.4] Therefore, as EA is to AB, so is EC to CD. [Margin: x — V.14] But EA is greater than EC; therefore AB will also be greater than CD. So fit to CD, within the circle AB, an equal straight line BF; and by the scholium to Prop. 28 of Book 3, the arc AB will be greater than the arc FB. Hence, since the arc CD is similar to the arc AB, the arc CD will be greater than would make it similar to FB itself. Therefore the equal straight lines CD, BF cut off unequal arcs from the unequal circles AB, CD, and the arc of the smaller circle is greater than would make it similar to the arc FB of the larger circle. Which was proposed.

Diagram. Two concentric circles about the centre E: the larger circle (through A, B) and the smaller circle (through C, D), with radii EA, EB cutting the smaller circle at C, D, and the chord BF equal to CD fitted into the larger circle.

- E (centre/lower): common centre, from which the radii EA, EB are drawn
- A (upper left): point where radius EA meets the larger circle
- B (upper right): point where radius EB meets the larger circle
- F (top, between A and B): endpoint of the chord BF (equal to CD) on the larger circle
- C (inner left): point where radius EA cuts the smaller circle
- D (inner right): point where radius EB cuts the smaller circle
- Chords AB, CD (parallel) and BF are drawn.

Hence it is evident that, all the more, a greater line cuts off from the smaller circle an arc greater than would make it similar to the one that a smaller line cuts off from the larger circle. For since the straight line CD, equal to BF, cuts off an arc CD greater than would make it similar to the arc FB, much more will a line greater than CD cut off a greater arc than would make it similar to the arc FB, since that line cuts off a greater arc than CD does, as we showed in the scholium to Prop. 28 of Book 3.

But this demonstration establishes the proposition only when the arcs cut off, BF and CD, are less than a semicircle, as is clear from the demonstration itself. For otherwise no angle would be formed at E, the common centre — which is nevertheless required for the demonstration. Yet it will nonetheless be true that, if an arc of the smaller circle less than a semicircle is greater than would make it similar to an arc of the larger circle less than a semicircle, then an arc of the

smaller circle greater than a semicircle is much greater than would make it similar to an arc of the larger circle less than a semicircle. And if it should ever happen that the straight line CD cuts off a semicircle from the smaller circle — as when it is the diameter of the circle — it is plainly established that the semicircle of the smaller circle is greater than would make it similar to an arc of the larger circle less than a semicircle; and then there will be no need of any other demonstration.

Hence too we shall show, with no trouble, that equal straight lines cut off from unequal circles arcs that are unqualifiedly and absolutely unequal — so that the arc of the smaller circle is simply greater than the arc of the larger circle, and not merely greater than would make it similar. For let the straight lines CD, BF be equal, and let CD cut off the arc CED of the smaller circle, and FB the arc FGB of the larger circle. I say that the arc CED is simply greater than the arc FGB. For when the straight line CD is made to coincide with the straight line FB, the arc CED will necessarily fall

will necessarily fall outside the arc FGB; and therefore arc CED will be greater than arc FGB, since the latter is contained wholly within the former — provided that both arcs are concave toward the same side and have the same endpoints, as Archimedes holds in the postulates prefixed to Book I of *On the Sphere and Cylinder*. Nor indeed will arc CED coincide with arc FGB or fall within it. For if it were said to coincide, then the whole circumference of circle CED would also coincide with the whole circumference of circle FGB, and so the circles would be equal — which is absurd, since they were posited unequal. But if arc CED be said to fall within arc FGB — of which kind is arc CAD — then, since (as we showed just above) arc CED, that is CAD, is too great to be similar to arc FGB, let arc BFH be taken similar to arc CAD, and therefore greater than arc FGB. Now, taking any point A whatever on arc CAD, let the straight lines AF, AB be drawn; and, the straight line FA being produced until it cuts arc FGB at G, let the straight lines GH, GB be drawn. Then, since arcs CAD and HFB are similar, the angles CAD and HGB standing in those segments will be equal. [Margin: Elements I.16] But since angle CAD is greater than angle CGB — an exterior angle greater than an interior one — and angle CGB is likewise greater than angle HGB (the whole greater than the part), angle CAD will be very much greater than angle HGB, which is absurd; for it was shown to be equal. Therefore arc CED will not fall within arc FGB; nor does it coincide with it, as was demonstrated. It will therefore fall outside; and so arc CED will be greater than arc FGB, as was stated. Which was the thing proposed.

From this it is plainly established that a greater line drawn from a smaller circle cuts off an unqualifiedly greater arc than the arc which a smaller line cuts off from a larger circle.

Diagram. Two figures accompany the lemma. The upper figure shows two unequal circular arcs sharing the same endpoints C and D (at left and right), the smaller arc lying inside the larger. Several straight lines (chords and radii) are drawn across them, meeting at interior points, and a lower point H is joined by lines to the upper region. The separate lower figure is a semicircle on the chord CD with apex E.

Upper figure:

- E (top apex): highest point on the outer arc
- G (upper, right of centre): point where the produced line FA meets arc FGB
- A (centre): point taken on arc CAD
- C (far left): left endpoint / left extremity of the chords
- F (left, just below C): point on the arcs near C
- I (centre-low): interior intersection of the drawn lines
- B (right): right endpoint
- D (right, near B): endpoint of the inner arc
- H (lower left): point joined to G and B

Lower figure (semicircle):

- C (left): left end of the chord
- E (top): apex of the semicircle
- D (right): right end of the chord

Since Euclid said much about the finding of proportional lines but nothing about the investigation of proportional surfaces or plane figures, I think it not out of place to append to this sixth book — as a kind of appendix — some problems and theorems, many of which turn on the finding of proportional surfaces and are not unpleasant to know. These I draw partly from skilled geometers, partly from my own discoveries, inasmuch as they are readily deduced from what Euclid has demonstrated. Here, then, we shall make our beginning.

I.

From a given rectilinear figure to cut off a required part, in such a way that both what is cut off and what remains are similar to a given rectilinear figure and similarly placed.

Let the third part be that which is to be cut off from the rectilinear figure A — a part similar and similarly placed to the figure B — and let there remain a rectilinear figure likewise similar to B and similarly placed. [Margin a: Elements VI.25] Construct a rectilinear figure CD equal to A, but similar and similarly placed to B; and on one side of it, CE, [Margin b: Elements VI.6] let a semicircle CFE be described. Then, the third part GE — namely the required part — having been cut off from CE, let GF be drawn perpendicular to CE, and let the straight lines CF, EF be joined; [Margin c: Elements VI.18] upon which let the rectilinear figures FH, FI be constructed, similar and similarly placed to CD. I say, then, that what is required has been done. [Margin d: Elements III.31] For since angle CFE is right — being an angle in a semicircle — [Margin e: Elements VI.31] the figure CD will be equal to the figures HF, FI together; and so, if the figure FI (similar and similarly placed to B) be cut off from the figure CD — that is, from A, its equal — there will remain the figure HF, likewise similar to B and similarly placed. That the figure FI cut off is a third part of the figure CD is shown thus. [Margin f: Elements VI.4] Since CG is to GF as CF is to FE, [Margin g: Elements VI.8] because triangles CGF, CFE are similar, and CG has to GE the ratio duplicate of the ratio of CG to GF (seeing that the three lines CG, GF, GE are proportional, by the corollary to Proposition 8 of this book), [Margin h: Elements VI.19 or 20] the figure HF likewise has to the figure FI the ratio duplicate of the ratio of the homologous sides CF, FE. Therefore, as CG is to GE, so is the figure HF to the figure FI, since these are the duplicates of two equal ratios. Compounding, then, as CE is to GE, so are the two figures HF, FI together — that is, the figure CD, which is equal to them — to the figure FI. But CE is triple GE, by construction. Therefore the figure CD is also triple the figure FI; and consequently FI is a third part of CD. Which was the thing proposed.

And if the required part — namely a third — is to be cut off without further qualification, it will be done most briefly by this method. [Margin i: Elements I.45] Let the given rectilinear figure A be reduced to an equal parallelogram GD; and from its side BD let DE, the required third part, be cut off; and through E let EF be drawn parallel to BG. I say that DF is a third part of DG — that is, of the given rectilinear figure A. [Margin k: Elements VI.1] For since DE is to DB as DF is to DG, and, by construction, DE is a third part of DB, DF too will be a third part of DG. Which was the thing proposed.

II.

Given two rectilinear figures, to find a third proportional.

Let two rectilinear figures A and BCD be given, of which a third proportional is to be found. [Margin l: Elements VI.25] Construct a rectilinear figure EFG equal to A, but similar and similarly placed to BCD. Then, on the homologous sides EF, BC, [Margin m: Elements VI.11] let a third proportional line HI be found; [Margin n: Elements VI.18] and upon HI let a rectilinear figure HIK be constructed, similar and similarly placed to EFG and BCD. I say that HIK is the third proportional. For since [Margin o: Elements VI.22] the lines EF, BC, HI are proportional, the figures EFG, BCD, HIK described upon them (being similar and similarly placed) will also be proportional. And since EFG was constructed equal to A, the figures A, BCD, HIK will also be proportional. Which was the thing proposed.

III.

Given three rectilinear figures, to find a fourth proportional.

Let three rectilinear figures A, BCDE, FGH be given, of which a fourth proportional is to be found. [Margin a: Elements VI.25] Construct a rectilinear figure IKLM equal to A, but similar and similarly placed to BCDE. Then, of the three lines IK, BC, FG, [Margin b: Elements VI.12] let a fourth proportional NO be found; [Margin c: Elements VI.18] and upon NO let a rectilinear figure NOP be constructed, similar and similarly placed to FGH. I say that the figure NOP is the fourth proportional. For since the four lines IK, BC, FG, NO are proportional, [Margin d: Elements VI.22] the similar and similarly placed figures described upon them — IL, BD, FGH, NOP — will also be proportional. And since IL was constructed equal to A, the four figures A, BD, FGH, NOP will also be proportional. Which was the thing proposed.

Diagram. The figures for Proposition III: the three given figures (a triangle A, a quadrilateral BCDE, and a triangle FGH) and the two constructed figures (a parallelogram IKLM and a triangle NOP).

- A: a triangle (the first given figure)
- B (lower left), C (lower right), D (upper right), E (upper left): the quadrilateral BCDE
- H (apex), F (lower left), G (lower right): the triangle FGH
- M (upper left), L (upper right), I (lower left) [?], K (lower right): the constructed parallelogram IKLM (lower-left vertex printed in an I/J form)
- P (apex), N (lower left), O (lower right): the constructed triangle NOP

IV.

Given two rectilinear figures, to find a mean proportional.

Let two rectilinear figures A, BCD be given, of which a mean proportional is to be found. [Margin a: Elements VI.25] Construct a rectilinear figure EFG equal to A, and similar and similarly placed to BCD. Then, of the two lines EF, BC, [Margin b: Elements VI.13] let a mean proportional HI be found; [Margin c: Elements VI.22] and upon HI let a rectilinear figure HIK be constructed, similar and similarly placed to EFG and BCD. I say that HIK is the mean proportional sought. For since the three lines EF, HI, BC are proportional, [Margin d: Elements VI.22] the figures described upon them — EFG, HIK, BCD — will also be proportional, being similar and similarly placed. Since, then, EFG was constructed equal to A, the figures A, HIK, BCD will also be proportional; that is, as A is to HIK, so is HIK to BCD; and consequently HIK is the mean proportional between A and BCD. Which was the thing proposed.

Another method. Let a mean proportional again be sought between the rectilinear figures A and B. [Margin e: Elements I.45] Construct any parallelogram CDEF equal to A, [Margin f: Elements VI.25] and a parallelogram EFGH equal to B but similar and similarly placed to CDEF. Let these parallelograms be joined at equal angles, so that DE, EI make one straight line; and consequently — by what we demonstrated at Proposition 15 of Book I — let FE, EG likewise form one straight line, and let the whole parallelogram KL be completed. I say that either EK or EL is a mean proportional between DF and GI — that is, between A and B. For since DF, GI are similar and similarly placed, DE is to EF as GH is to HI, that is, as EI is to EG, [Margin g: Elements I.34] because the lines EI, EG are equal to the lines GH, HI. Alternating, then, DE is to EI as FE is to EG. [Margin h: Elements VI.1] But DE is to EI as DF is to EK, and FE is to EG as EK is to GI. Therefore DF is to EK as EK is to GI; and consequently EK is a mean proportional between DF and GI — that is, between A and B. Which was the thing proposed.

This can also be confirmed in the following way. Since DE, GI are similar and similarly placed, [Margin i: Elements VI.26] they stand about the same diameter. Hence the complements EK, EL will be equal. But DF is to EK as EL is to GI, [Margin k: Elements VI.1] because each ratio is the same as the ratio of DE to EI. Therefore DF is to EK as EK is to GI. Which was the thing proposed.

Diagram. The figures for the first construction of Proposition IV: a triangle A (the first given figure), a triangle BCD, a triangle EFG, and the constructed triangle HIK.

- A: a right-angled triangle (the given figure A)
- D (apex), B (lower left), C (lower right): triangle BCD
- G (apex), E (lower left), F (lower right): triangle EFG

- K (apex), H (lower left), I (lower right): the constructed triangle HIK

Diagram. The figures for the alternative (parallelogram) construction of Proposition IV: a right triangle A, a triangle B, and the joined parallelograms CDEF and ECHI completed into the parallelogram KL.

- A: a right triangle
- B: a small triangle
- C (upper left), F (upper, centre), K (upper right): upper vertices of the joined parallelograms
- D (middle left), E (middle, centre), I (middle right): the middle row (DE, EI forming one straight line)
- L (lower left), G (lower, centre), H (lower right): lower vertices

V.

On a given rectilinear figure, to construct two rectilinear figures equal to it, which are similar and similarly described to any given rectilinear figure whatever, and which have between themselves any proposed ratio.

Let a rectilinear figure A be given, and a ratio of the line B to C; and let it be required to construct two rectilinear figures which are equal to A, which have the ratio of B to C, and which are similar and similarly placed to any given figure D. [Margin a: Elements VI.25] Construct a rectilinear figure EFGH equal to A, and similar and similarly placed to D. Then, its side EH being divided at I in the ratio of B to C — by the method we demonstrated at Proposition 10 of this book — let a semicircle EKH be described about EH; and from I let the perpendicular IK be drawn to EH, and the straight lines EK, HK be joined. [Margin b: Elements VI.18] Now upon EK, KH let the rectilinear figures EKLM, KHNO be described, similar and similarly placed to EG (or to D); which figures I say are also equal to EG (or to A) and have the given ratio B to C. [Margin c: Elements III.31] For since angle EKH, standing in a semicircle, is right, [Margin d: Elements VI.31] the figures EL, HO will be equal to the figure EG, being similar to each other and similarly described. [Margin e: Elements VI.4] And since EI is to IK as EK is to KH — the triangles EIK, EKH being similar — while EI is to IH in the ratio duplicate of the ratio of EI to IK (because the three lines EI, IK, IH are proportional, by the corollary to Proposition 8 of this book), [Margin f: Elements VI.19 or 20] and likewise EL is to HO in the ratio duplicate of that which the side EK has to the homologous side KH, therefore, as EI is to IH — that is, as B is to C — so is EL to HO. Given, then, the rectilinear figure A, we have exhibited two figures at once

equal to it, EL and HO, which are similar and similarly placed to the given figure D, and which have between themselves the given ratio of B to C. Which was the thing proposed.

Diagram. The figure for Proposition V: a square EFGH with a semicircle EKH described on its upper side EH, the perpendicular IK, and the two rectilinear figures EKLM and KHNO described on EK and KH. Two line-segments B and C, and a rectangle D, are shown separately at the left.

- E (upper left of the square), H (upper right): endpoints of the diameter EH
- F (lower left), G (lower right): lower vertices of the square EFGH
- I (on EH, between E and H): point dividing EH; foot of the perpendicular
- K (apex of the semicircle): point where the perpendicular IK meets the semicircle
- L, M: the further vertices of the figure EKLM on EK
- N, O: the further vertices of the figure KHNO on KH
- B, C: two separate straight-line segments (the given ratio)
- D: a separate rectangle (the figure to which the constructions are similar)

VI.

On a given rectilinear figure, to exhibit two rectilinear figures equal to it, which are similar and similarly described to any given rectilinear figure, and whose homologous sides have a given ratio to one another.

Let a rectilinear figure A be given, and a ratio of the line B to the line C; and let it be required to construct two rectilinear figures equal to A, and similar and similarly placed to a given figure D, whose homologous sides have the ratio of B to C. [Margin a: Elements VI.11] Let a third proportional E be found to B and C; [Margin b: Elements VI.25] and let a rectilinear figure FGH be made equal to A, and similar and similarly placed to D. Then, the side FH being divided at I in the ratio of B to E — as we showed at Proposition 10 of this book — let a semicircle FKH be described about FH; and from I let the perpendicular IK be drawn to FH, and the straight lines FK, HK be joined. [Margin c: Elements VI.18] Now upon FK, HK let the rectilinear figures FKL, HKM be described, similar and similarly placed to FGH (or to D). I say that these figures are equal to FGH (or to A), and that their homologous sides FK, HK have the given ratio of the line B to the line C. [Margin d: Elements III.31] For since angle EKH [recte FKH] is right in a semicircle, [Margin e: Elements VI.31] the figures FKL, HKM will be equal to the figure FGH, and therefore to A. [Margin f: Elements VI.4] And since FI is to IK as FK is to HK, on account of the similarity of the triangles FIK, FKH — while FI is to IH in the

ratio duplicate of the doubling of FI to IK (because the three lines FI, IK, IH are proportional, by the corollary to Proposition 8 of this book) — FI is therefore to IH in the ratio duplicate of the ratio of the homologous sides FK, HK. Likewise the ratio of B to E (equal to the ratio of FI to IH, by construction) is the duplicate of the ratio of B to C, by definition. Therefore the ratio of FK to HK will be the same as that of B to C, since the duplicates of these ratios — that of FI to IH and that of B to E — are equal. The proposition therefore stands established.

Diagram. The figure for Proposition VI: a rectangle A, a triangle D, and the semicircle FKH described on FH, with the perpendicular IK, the joined lines FK, HK, and the figures FKL, HKM described on them. Three line-segments B, C, E are shown at the lower left.

- A: a rectangle (the given figure)
- D: a triangle (the figure to which the constructions are similar)
- F (lower left of the semicircle), H (lower right): endpoints of the diameter FH
- I (on FH between F and H): point dividing FH; foot of the perpendicular
- K (apex): point where the perpendicular meets the semicircle
- L (upper left), M (upper right): the further vertices of the figures FKL and HKM
- G (lower point below FH): apex of the figure FGH
- B, C, E: three separate straight-line segments

VII.

Given two rectilinear figures, to construct a rectilinear figure equal to them, which is similar and similarly placed to any given rectilinear figure.

Let two rectilinear figures A and B be given, to which an equal figure is to be constructed, similar and similarly placed to a figure C. [Margin a: Elements VI.25] Let DEF be made equal to A, but similar and similarly placed to C; and likewise let GFH be constructed equal to B, but similar to the same C and similarly placed. Then let the figures DEF, GFH be so joined together that their homologous sides EF, FH [?] form a right angle EFH, subtended by the straight line EH; [Margin b: Elements VI.18] upon which let a rectilinear figure IHE be described, similar and similarly placed to DEF and GFH — that is, to C. [Margin c: Elements VI.31] It is then evident that EHI is equal to the two figures DEF, GFH together, and therefore to the two figures A and B. Which was the thing proposed.

A shorter method. Construct a parallelogram equal to the two rectilinear figures A and B, by the method we taught at Proposition 45 of Book I. [Margin d: Elements VI.25] For if to this parallelogram we construct an equal rectilinear figure EHI, which is similar and similarly placed to the other given figure C, then the constructed figure EHI will be equal to the two figures A, B, and similar and similarly placed to the figure C. Which was to be done.

Diagram. The figure for Proposition VII: three separate triangles A, B, C, and the joined construction below — triangles DEF and GFH set at the right angle EFH, with the figure IHE described on the subtending line EH.

- A: a triangle (first given figure)
- B: a triangle (second given figure)
- C: a triangle (the figure to which the construction is similar)
- D (upper left), F (upper centre), G (upper right): upper vertices of the joined triangles DEF, GFH
- E (lower left), H (lower right): endpoints of the subtending line EH
- I (lowest point): apex of the figure IHE described on EH

VIII.

If in a circle two straight lines cut one another, the segments of the one will be reciprocal to the segments of the other.

In the circle ABCD let the straight lines AC, BD cut one another at E. I say that the segments AE, EC are reciprocal to the segments BE, ED: that is, that as AE is to BE, so is ED to EC; or as AE is to ED, so is BE to EC. [Margin a: Elements III.25 [?] — expected III.35 (rectangle under segments of intersecting chords); printed digit uncertain] For since the rectangle contained by AE, EC is equal to the rectangle contained by BE, ED, [Margin b: Elements VI.14] the sides about equal angles will be reciprocal. Which was the thing proposed.

Diagram. The figure for Proposition VIII: a circle ABCD in which the two chords AC and BD cross at the interior point E.

- A (top): endpoint of chord AC
- B (left): endpoint of chord BD
- C (bottom): endpoint of chord AC
- D (right): endpoint of chord BD
- E (centre): the point where the chords AC, BD intersect
- M (interior, upper): an additional marked point on the arc

IX.

If some point be taken outside a circle, and from it two straight lines fall upon the circle cutting it: the whole lines, together with the segments outside the circle, will be reciprocal. And if from the same point a line be drawn to touch the circle, this will be a mean proportional between any line that cuts the circle and its exterior segment.

IX. (demonstration)

Outside the circle ABCD let a point E be taken, from which the straight lines EC, ED fall, cutting the circle at A and B. I say that the lines EC, EB are reciprocal to the lines ED, EA — that is, that as EC is to ED, so EA is to EB; and likewise, as EC is to EA, so ED is to EB. For when the line EF is drawn tangent to the circle at F, [Margin: 36. tertij → Elements III.36 (secant/tangent)] the rectangle under EC, EB will be equal to the square on EF; and likewise the rectangle under ED, EA will be equal to that same square on EF. Therefore the rectangles under EC, EB and under ED, EA will be equal. [Margin: 14. sexti → Elements VI.14] Hence their sides about the equal angles are reciprocal. [Margin: 36. tertij → Elements III.36] Now since the square on EF is equal both to the rectangle under EC, EB and to the rectangle under ED, EA, [Margin: 17. sexti → Elements VI.17] the three lines EC, EF, EB will be proportional, and so too the three ED, EF, EA; and thus EF is a mean proportional between any line that cuts the circle and its exterior segment. Which was the thing proposed.

Diagram. A circle (ABCD) with an external point E at the upper right, from which two secants and one tangent are drawn.

- E (upper right, outside the circle): the external point from which the lines are drawn
- F (upper left, on the circle): point of tangency of the tangent EF
- A (right, near intersection on the circle): nearer point where the secant EAC meets the circle
- B (right, near intersection, just below A): nearer point where the secant EBD meets the circle
- C (left, on the circle): farther intersection of the first secant
- D (bottom, on the circle): farther intersection of the second secant

X.

If two straight lines cut one another, and from two of their endpoints perpendiculars are dropped each onto the other line, there will be two

lines — one lying between one of the endpoints and the intersection, the other between the intersection and the perpendicular drawn from the assumed endpoint of the former line — which are reciprocally proportional to two others enclosed in the same way.

Let two straight lines AB, CB cut one another at B, and from the endpoints A, C let perpendiculars be dropped onto them: AD onto CB, and CE onto AB. These perpendiculars will fall on AB, CB extended beyond B if the angle ABC is obtuse, but inward upon the lines themselves if that angle is acute, as the figures show. I say that the lines AB, BE (the former of which lies between the endpoint A and the intersection B, the latter between the intersection B and the perpendicular CE, which of course is drawn to the assumed line AB) are reciprocal to the two lines CB, BD (which are enclosed between corresponding endpoints) — that is, that as AB is to BC, so is BD to BE; and likewise, as AB is to BD, so is BC to BE. For since the angles ABD, ADB of triangle ABD are equal to the angles CEB, of triangle CBE — for ADB and CEB are right angles; [Margin: 15. primi → Elements I.15] and ABD, CBE are equal, being vertical in the first figure, while in the second figure they are one and the same angle — the triangles ABD, CBE will be equiangular. [Margin: 4. sexti → Elements VI.4] Therefore, as AB is to BD, so is CB to BE; and hence, by alternation also, as AB is to BC, so is BD to BE. Which was the thing proposed.

Moreover, by the same reasoning the segments of the perpendiculars AD, CE, cutting one another at F in the second figure, will be reciprocal. For since the triangles AFE, CFD are equiangular, [Margin: 4. sexti → Elements VI.4] as AF is to FE, so will CF be to FD; and by alternation also, as AF is to CF, so is FE to FD. Which was the thing proposed.

Diagram. The first (obtuse-angle) figure for Proposition X: two straight lines crossing in an X, with perpendiculars falling outside.

- A (upper left): endpoint of one line
- C (upper right): endpoint of the other line
- B (center): the intersection of the two lines
- D (lower left): foot of the perpendicular from A
- E (lower right): foot of the perpendicular from C

Diagram. The second (acute-angle) figure for Proposition X, with the perpendiculars falling inward and meeting at F.

- A (upper left): endpoint of one line

- C (right): endpoint of the other line
- F (center): intersection of the two perpendiculars AD, CE
- D (right of F): foot of one perpendicular
- E (lower left): foot of the other perpendicular
- B (bottom): the intersection of the two original lines

XI.

In a parallelogram, two straight lines parallel to the sides and cutting one another divide the parallelogram into four proportional parallelograms.

In the parallelogram ABCD let two straight lines EF, GH, parallel to the sides AD, DC, cut one another at I. I say that the four parallelograms EG, GF, BI, IC are proportional. [Margin: 1. sexti → Elements VI.1] For since, as EI is to IF, so is EG to GF; and likewise, as EI is to IF, so is BI to IC; [Margin: 11. quinti → Elements V.11] it will also be that, as EG is to GF, so is BI to IC. Which was the thing proposed.

Diagram. A parallelogram divided into four smaller parallelograms by two lines parallel to the sides.

- A (top left), G (top center), D (top right): the top side, with G where the line GH meets it
- E (middle left), I (center), F (middle right): the line EF, meeting GH at the center I
- B (bottom left), H (bottom center), C (bottom right): the bottom side, with H where GH meets it

XII.

Every quadrilateral is divided by two diagonals cutting one another into four proportional triangles.

Let the diagonals AC, BD, cutting one another at E, divide the quadrilateral ABCD. I say that the four triangles AED, CED, AEB, CEB are proportional. [Margin: 1. sexti → Elements VI.1] For, as AE is to EC, so is triangle AED to triangle CED, and triangle AEB to triangle CEB. [Margin: 11. quinti → Elements V.11] Hence, as triangle AED is to triangle CED, so is triangle AEB to triangle CEB. By the same reasoning you will show that, as BEA is to DEA, so is BEC to DEC, [Margin: 1. sexti → Elements VI.1] since each ratio is the same as the ratio of BE to ED. The thing proposed is therefore established.

Diagram. A quadrilateral with its two diagonals meeting at an interior point.

- B (bottom left), C (bottom right): the other two vertices
- E (center): the intersection of the diagonals AC and BD

XIII.

In a right triangle in which the perpendicular dropped from the right angle cuts the base in extreme and mean ratio, the three sides are continuously proportional. And if the three sides of a right triangle are continuously proportional, the perpendicular dropped to the base from the right angle cuts the base in extreme and mean ratio.

In the right triangle ABC, let the perpendicular AD dropped from the right angle A cut the base BC at D in extreme and mean ratio, the greater segment being BD; and hence, by the ninth theorem appended to Proposition 47 of Book I, the side AB is greater than the side AC. I say that the three sides BC, BA, AC are continuously proportional. For since by hypothesis, as BC is to BD, so is BD to DC, [Margin: 17. sexti → Elements VI.17] the square on BD will be equal to the rectangle under BC, CD. Again, since by the corollary to Proposition 8 of this book AC is a mean proportional between BC and CD, [Margin: 17. sexti → Elements VI.17] the square on AC will likewise be equal to that same rectangle under BC, CD. Therefore the squares on BD and AC will be equal to one another, and consequently the lines themselves will also be equal. But by the corollary to Proposition 8 of this book, AB is a mean proportional between BC and BD. Therefore that same AB will be a mean proportional between BC and AC — that is, as BC is to AB, so is AB to AC. Which was the thing proposed.

Diagram. A right triangle inscribed in a semicircle, with the perpendicular from the right-angle vertex to the base.

- A (apex, on the semicircle): the right-angle vertex
- B (bottom left): one end of the base and diameter
- D (base, between B and C): foot of the perpendicular AD
- C (bottom right): the other end of the base and diameter
- (a dotted semicircle stands on BC as diameter)

Next, in the right triangle ABC let the three sides BC, AB, AC be continuously proportional — that is, let BC be to AB as AB is to AC — and let the perpendicular AD be dropped to the base BC. I say that BC is cut at D in extreme and mean ratio. For since, as BC is to AB, so is AB to AC; and also, as BC is to AB, so is AB to BD (because AB is a mean proportional between BC and BD, by the corollary to

Proposition 8 of this book), [Margin: 11. quinti → Elements V.11] it will be that, as AB is to AC, so is AB to BD; [Margin: 9. quinti → Elements V.9] and consequently AC and BD will be equal. [Margin: 7. quinti → Elements V.7] Therefore, as AC is to CD, so will BD be to CD. But as AC is to CD, so is BC to AC — since, by the corollary to Proposition 8 of this book, AC is a mean proportional between BC and CD. [Margin: 11. quinti → Elements V.11] Therefore it will also be that, as BC is to AC (that is, to BD), so is AC (that is, BD) to CD; and on that account BC is cut at D in extreme and mean ratio. Which was the thing proposed.

And so, if upon a given straight line BC a right triangle is to be constructed whose three sides are continuously proportional, the given line BC must be cut in extreme and mean ratio at D. Then, a semicircle BAC having been described about this same given line BC, the perpendicular DA must be erected upon BC, and the lines BA, CA joined. For the triangle ABC will be right-angled, [Margin: 31. tertij → Elements III.31] since the angle BAC in the semicircle is a right angle; and hence, since the perpendicular AD cuts the base in extreme and mean ratio, the three sides will be continuously proportional, as was just demonstrated.

XIV.

From a given point on the side of a triangle, to draw a straight line that divides the triangle into two parts according to a given ratio.

Let there be a triangle ABC, and let it be required from a given point D on its side BC to draw a straight line that cuts the triangle into two parts according to the given ratio of E to F. Let BC be divided at G in the ratio of E to F, and let the point G fall first upon the given point D, as in the first figure, and let the line DA be drawn. [Margin: 1. sexti → Elements VI.1] Since, then, as BD is to DC, so is triangle BDA to triangle CDA, the line DA will cut the given triangle in the given ratio of BG to GC — that is, of E to F. Which was to be done.

Diagram. The first figure for Proposition XIV: the dividing point coincides with the point of division of the base.

- A (apex): the top vertex
- H (interior, right of center): auxiliary point
- B (bottom left): base vertex
- D (base): the given point, here coinciding with G
- G (base, near D): point dividing BC in the given ratio
- C (bottom right): base vertex

Next, let the point G fall between C and D, as in the second figure. Let the line DA then be drawn, and through G let GH be drawn parallel to it, and the line DH joined. I say that the line DH cuts the given triangle in the given ratio — that is, that the trapezium BDHA is to the triangle CDH as E is to F, or as BG is to GC. For when the line is drawn, [Margin: 37. primi → Elements I.37] the triangles HGA, GHD will be equal, since they stand on the same base GH and between the same parallels GH, DA. Adding, then, the common triangle CGH, the triangles CGA, CDH become equal; [Margin: 7. quinti → Elements V.7] and hence the triangle ABC will have the same ratio to CGA as to CDH. [Margin: 17. quinti → Elements V.17] Therefore, by separation, as triangle BGA is to triangle CGA, so is the trapezium BDHA to the triangle CDH. [Margin: 1. sexti → Elements VI.1] But BGA is to CGA as BG is to GC. Therefore the trapezium BDHA will also be to the triangle CDH as BG is to GC — that is, as E is to F. Which was the thing proposed.

Diagram. The second figure for Proposition XIV, where G falls between C and D and the line DH is drawn.

- A (apex): the top vertex
- E (upper right): endpoint marking the given ratio
- F (upper right, below E): endpoint marking the given ratio
- B (bottom left): base vertex
- D (base): the given point
- G (base, between D and C): point dividing BC in the given ratio
- C (bottom right): base vertex

Let the point G fall, thirdly, between B and D, and let the line DA be drawn, through which again a parallel GH is drawn through G. I say once more that the line DH, when drawn, cuts the triangle ABC in the given ratio of E to F — that is, that the triangle BDH is to the trapezium CDHA as E is to F. For when the line GA is drawn, [Margin: 37. primi → Elements I.37] the triangles HGA, GHD will, as before, be equal; and, the common triangle BGH being added, BGA and BDH become equal. [Margin: 7. quinti → Elements V.7] Hence ABC is to BGA as it is to BDH. [Margin: 17. quinti → Elements V.17] Therefore, by separation, as CGA is to BGA, so is the trapezium CDHA to the triangle BDH; and by conversion, as BGA is to CGA, so is BDH to the trapezium CDHA. [Margin: 1. sexti → Elements VI.1] But BGA is to CGA as BG is to GC. Therefore BDH will also be to the trapezium CDHA as BG is to GC — that is, as E is to F. Which was the thing proposed.

Diagram. The third figure for Proposition XIV, where G falls between B and D.

- A (apex): the top vertex

- H (on the left side AB): where the parallel GH meets side AB
- B (bottom left): base vertex
- G (base, between B and D): point dividing BC in the given ratio
- D (base, right of G): the given point
- C (bottom right): base vertex

From this it is clear in what way a required part is to be cut off from a triangle by a straight line drawn from any given point on a side. For if, by a straight line drawn from a given point, the triangle is divided in a multiple ratio whose denominator is smaller by a unit than the denominator of the required part — for instance, in the triple ratio if a fourth part is required, and so on — then what is commanded will be done, as is evident. For the whole triangle will then have to the segment cut off a multiple ratio whose denominator is equal to the denominator of the required part, since to the earlier denominator of the assumed multiple ratio is added the unit that was previously lacking.

XV.

Given a rectilinear figure, to describe a rectilinear figure similar and similarly situated to it, greater or smaller according to a given ratio.

Let A be a given rectilinear figure, to which a greater figure, similar and similarly situated, is to be described according to the given ratio of B to C. Given three straight lines B, C, and DE (let DE be any one side of the given rectilinear figure), [Margin: 12. sexti → Elements VI.12] let a fourth proportional F be found. Then, given the two lines DE and F, [Margin: 13. sexti → Elements VI.13] let a mean proportional GH be found; [Margin: 18. sexti → Elements VI.18] upon which, let a rectilinear figure I be described, similar and similarly situated to A. I say that I is greater than A according to the given ratio of B to C. For since the three lines DE, GH, and F are proportional, then by the corollary to Proposition 19 or 20 of this book, as DE, the first, is to F, the third — that is, by construction, as B is to C — so is the rectilinear figure A, upon the first, to the rectilinear figure I, upon the second, which is similar and similarly situated to it. Which was to be done.

In no other way, given the rectilinear figure A, shall we describe a smaller figure I, similar and similarly situated to it, according to the given ratio of B to C. You see it done, just so, in this figure; for the construction and demonstration are altogether the same.

Easily, then, from these we shall double, triple, or quadruple any square or other rectilinear figure, and so on; and we shall likewise construct another figure that

is its half, or its third part, or its fourth, or its fifth, and so on — the similarity of the rectilinear figures being nonetheless always kept the same, just as the similarity of squares remains the same. For if the ratio of B to C is taken as 1 to 2, or 1 to 3, or 1 to 4, and so on; or again as 2 to 1, or 3 to 1, or 4 to 1, and so on; and the rest is carried out as before — then a similar and similarly described figure will be obtained, which will be the double of the proposed rectilinear figure, or its triple, or its quadruple, and so on; or which will be its half, or its third part, or its fourth, and so on, of that which is proposed.

Diagram. The construction for enlarging a figure: three marked segments above a smaller and a larger similar triangle.

- F (top segment, divided into parts): the fourth proportional line
- C (segment below F): one of the given lines
- B (short segment): one of the given lines
- A (smaller triangle) on base D–E: the given figure
- I (larger triangle) on base G–H: the figure to be described, similar to A

Diagram. The construction for reducing a figure: marked segments above a larger and a smaller similar triangle.

- B (top segment, divided): given line
- C (short segment): given line
- A (larger triangle) on base D–E: the given figure
- I (smaller triangle) on base G–H: the figure to be described, similar to A

Nor does it seem right to omit the method of Albrecht Dürer [Alberti Dureri], by which he easily doubles, triples, quadruples, and so on, any given square or parallelogram. For from this we shall likewise construct, for any given rectilinear figure, a similar and similarly described figure, greater or smaller according to any given ratio. And although Dürer offers no reasoning for this method but simply proposes it, still his demonstration does not differ much from the preceding one, as we shall shortly show.

Let the square ABCD, then, be one to be made fivefold. Let the side AB be extended toward B by any amount, and from the point B, beginning there, let five parts equal to AB be taken up to E, so that BE is five times AB. Then, the whole line AE being bisected at F, let a semicircle AGE be described from F with radius FA (or FE), and let the side BC be extended to the circumference at G. I say that the square BGHI, described on BG, is fivefold the square ABCD. For by the corollary to Proposition 13 of this book, BG is a mean proportional between EB

and BA. Therefore, as EB, the first, is to BA, the third, so is BH, the square on the second, to AC, the square on the third, by the corollary to Proposition 20 of this book. But EB, by construction, is five times AB. Therefore the square BH will also be five times the square AC. Which was the thing proposed.

And if the line BE is taken six times the side AB, the square on the line BG will also be sixfold the square ABCD. But if BE is a third part of AB, the square BH will also be a third part of the square AC. In short, in whatever ratio BE is taken to AB, the square BH will have the same ratio to the square AC.

Diagram. Dürer's construction for multiplying a square: a semicircle on AE, with the original square ABCD at the right and the larger square BGHI erected on BG.

- E (left end of the baseline): endpoint of the extended line AE
- I (baseline, left of F): corner of the larger square BGHI
- F (baseline, center): midpoint of AE and center of the semicircle
- B (baseline, right of center): shared corner of both squares
- A (right end of the baseline): corner of the original square
- H (upper left): corner of the larger square
- G (upper right, on the semicircle): where BC extended meets the circle
- C (middle, above B): corner of the original square ABCD
- D (middle, above A): corner of the original square ABCD

Again, let there be a rectangle ABCD, to which a similar and similarly situated figure, its double, is to be found. From the side AB extended let BE be taken, double AB. Then the whole line AE being bisected at F, and a semicircle described from F as before, and CB extended to G, then BG will be one side of the required rectangle. Therefore if AH is cut off equal to BG, and through H a line HI is drawn parallel to BC, meeting the diagonal AC extended at I, and the parallelogram H is completed, [Margin: 24. sexti → Elements VI.24] then HK will be similar and similarly situated to BD; and I also affirm that it is the double of BD. For since the three lines EB, BG, BA are proportional, by the corollary to Proposition 13 of this book, it will be, as before, that as EB, the first, is to BA, the third, so is the rectangle HK, upon AH, the second (for AH was taken equal to BG, the second), to the rectangle BD, upon the third AB, which is similar and similarly described. Which was the thing proposed.

In the same way, if upon AB any rectilinear figure whatever has been constructed, the figure described from BG similar and similarly situated to it will be its double. And in this way the figure from BG will always have to the similar

figure from AB the same ratio that the line EB is set to have to the line BA, by construction.

It is evident that this method, together with its demonstration, does not differ from the one we set forth earlier, except that this one at the same time furnishes the finding of the mean proportional line. For this reason Dürer joins the lines EB, BA into one straight and continuous line, since they have the given ratio, so that at once, by a single operation, he may obtain the mean proportional, and so on.

Diagram. Dürer's construction for doubling a rectangle: a semicircle on the baseline with the rectangle BD at the right and the constructed rectangle at the lower left.

- G (top, on the semicircle): where CB extended meets the circle
- E (left end of the baseline): endpoint of the extended line
- F (baseline, center): midpoint and center of the semicircle
- H (baseline, right of F): point where AH is cut off equal to BG
- B (baseline, right of H): shared corner
- A (right end of the baseline): corner of the original rectangle
- C (middle): corner of the original rectangle ABCD
- D (middle right): corner of the original rectangle ABCD
- I (bottom left): where HI meets the extended diagonal
- K (bottom right): corner of the completed parallelogram

XVI.

In any given triangle, to describe a square:

(Continuation of the construction of appended Proposition XVI, "In any given triangle, to describe [inscribe] a square." The enunciation and catchword "SIT" stood at the end of the preceding page; Clavius's construction and proof follow.)

Let ABC be the given triangle, acute-angled. From any vertex A drop the perpendicular AD to BC; by the scholium to Proposition 13 of Book 2 [Elem. II.13] it falls inside the triangle. Cut this perpendicular at E — by the method we taught in the scholium to Proposition 10 of this book [Elem. VI.10] — so that AE is to ED as AD is to BC. Next, through E draw FG parallel to BC. Finally, from F and G draw FH and GI parallel to DE. I say that the rectilinear figure FGIH, inscribed in triangle ABC, is a square.

For since FG is parallel to BC, then by the scholium to Proposition 4 of this book [Elem. VI.4] BD is to DC as FE is to EG; and, *componendo*, BC is to DC as FG is to EG.

[Margin: a — 4.sex. (Elem. VI.4)] But DC is to AD as EG is to AE, because, by the corollary to Proposition 4 of this book [Elem. VI.4], the triangles ADC and AEG are similar. [Margin: b — 22.quin. (Elem. V.22)] Therefore, *ex aequali*, BC is to AD as FG is to AE. And since by construction AD is to BC as AE is to ED, [Margin: c — 22.quin. (Elem. V.22)] then again, *ex aequali*, BC is to BC as FG is to ED. But BC is equal to BC — indeed it is the very same line. Therefore FG is also equal to ED.

[Margin: d — 34.pri. (Elem. I.34)] Hence, since FG is equal to HI, and ED is equal to EH and GI, the four sides FG, GI, IH, HF will be equal to one another. [Margin: e — 29.pri. (Elem. I.29)] And since the angles EDH and FHD together equal two right angles — and EDH is right by construction — FHD will also be right. Therefore, by what we demonstrated at Definition 1 of Book 2 [Elem. II, def. 1], the remaining angles HFG, FGI, GIH of the parallelogram FGIH are also right; and consequently the figure FGIH [text: "FI"] is a square. Which is what was proposed.

We shall solve the same problem in exactly the same way if the given triangle is right-angled or obtuse-angled, provided we drop the perpendicular from the right or the obtuse angle, as appears in the latter two figures. For in that way the perpendicular AD will always fall inside the triangle, by the scholium to Proposition 13 of Book 2 [Elem. II.13].

Diagram. An acute triangle with an inscribed square, illustrating Proposition XVI.

- A (apex): vertex from which the perpendicular AD is dropped
- B (bottom-left): base vertex
- C (bottom-right): base vertex
- F (upper-left): top-left corner of the inscribed square, on side AB
- E (top-middle): point on FG where the perpendicular AD crosses
- G (upper-right): top-right corner of the inscribed square, on side AC
- H (base): foot of the square's left side, on BC
- D (base): foot of the perpendicular AD, on BC
- I (base): foot of the square's right side, on BC
- The inscribed square is FGIH (with FH and GI its vertical sides)

Diagram. A second triangle with an inscribed square (one of the "latter two triangles" — the right/obtuse cases of Prop. XVI).

- A (apex), B (bottom-left), C (bottom-right): triangle vertices
- F (upper-left), E (top-middle), G (upper-right): top edge of the inscribed square

- H, D, I (on the base BC): feet of the square's sides and of the perpendicular AD

Diagram. A third triangle with an inscribed square, the perpendicular still falling within it. Printed caption beneath: "semper cadet perpendicularis AD, intra triangulum, ex scholio propos. 13. lib. 2." — "the perpendicular AD always falls inside the triangle, by the scholium to Proposition 13 of Book 2."

- A (apex), B (bottom-left), C (bottom-right): triangle vertices
- F (upper-left), E (top-middle), G (upper-right): top edge of the inscribed square
- P (far bottom-left), H, D, I (on the base): the base points, with P marking the extension of the base beyond the triangle

Now if one wishes to describe the square in a right triangle so that two of its sides rest on the two sides of the triangle about the right angle: we divide the perpendicular AB at D so that AD is to DB as AB is to BC; through D we draw DE parallel to BC, and through E another parallel EF to AB.

[Margin: f — 4.sex. (Elem. VI.4)] Since, then, BC is to AB as DE is to AD — because the triangles ABC and ADE are similar, by the corollary to Proposition 4 of this book [Elem. VI.4] — and since by construction AB is to BC as AD is to DB, [Margin: g — 22.quin. (Elem. V.22)] it follows *ex aequali* that BC is to BC as DE is to DB. But BC is equal to itself — indeed it is the same line. Therefore DE is also equal to DB; and hence, as before, DEFB is a square. Which is what was proposed.

But more ingenious than this problem of Commandino's [Federico Commandino] is the one that follows.

Diagram. A right triangle with an inscribed square resting on the two legs about the right angle.

- A (top): apex
- B (bottom-left): the right angle
- C (bottom-right): base vertex
- D (on side AB, left): upper-left corner of the square
- E (on hypotenuse AC, right): interior corner of the square
- F (on base BC): lower corner of the square
- The inscribed square is DEFB

XVII.

Within a given square, to describe another square in a given ratio of greater inequality. But the given ratio must not be greater than double [2:1].

Let ABCD be the square within which another square is to be described, such that the square ABCD has to it the same ratio of greater inequality that the line E has to the line F — whatever that ratio may be, provided it is not greater than double. For if the sides of the square are bisected and the points of division joined by straight lines, a square will be inscribed within the other, having the same center as it, as we demonstrated at the end of Book 4.

And since the circle inscribed in the square ABCD is circumscribed about that inscribed square — as is clear in this figure — the square ABCD will be double the inscribed square, by the scholium to Proposition 9 of Book 4 [Elem. IV.9]. Since, then, no smaller square can be described within the square ABCD than the one whose circumscribed circle touches the sides of ABCD — as is evident — it clearly follows that the square ABCD can have to no inscribed square a ratio greater than double.

Let the given ratio E to F, then, be less than double — namely sesquialterate [3:2]. By Proposition 15 of this scholium find a square to which the given square ABCD has the given ratio E to F. Its semidiameter will be greater than the semidiameter of the square whose circumscribed circle touches the sides of ABCD (which square, as we said, is half of ABCD), but less than the semidiameter of the square ABCD.

Diagram. A small square containing an inscribed circle, and within the circle a second (diagonal) inscribed square, with the diagonals drawn — illustrating that the outer square is double the inner. No vertex letters are printed on this figure.

Therefore, if from the center G of the given square a circle is described equal to the one described about the square just found, it will cut the sides of the square ABCD at the points H, I, K, L, M, N, O, P. Join the straight lines HK, KM, MO, OH, leaving the four points I, L, N, P in the middle. I say that HKMO is a square described in the circle HIKLMNOP, and hence equal to the one that was found — so that the square ABCD has to the square HKMO [text: "HK, MO"] the given ratio E to F.

For, a circle having been described about the given square ABCD from the center G, and perpendiculars GQ, GR drawn from G to the sides AD, AB: [Margin: a —

3.ter. (Elem. III.3)] both the straight lines AD, AB and the straight lines HI, OP will be bisected at Q, R. And since AD, AB are equal, [Margin: b — 14.ter. (Elem. III.14)] they are equally distant from the center G, and therefore HI, OP are likewise equally distant from the same center. [Margin: c — 14.ter. (Elem. III.14)] Hence HI, OP will be equal, and consequently

their halves QH, QI, RO, RP will be equal to one another. Moreover the halves QA, QD, RA, RB of the equal sides are also equal. Therefore, if the former are subtracted from the latter, the remainders HA, ID, PA, OB will be equal. By the same reasoning, if other perpendiculars are drawn to the sides BC, CD, the lines NB, MC, LC, KD will be shown equal both to one another and to those four HA, ID, PA, OB.

Again, since HI, OP are equal, if the equals ID, PA are added, the wholes HD, AO become equal. And for the same reason BM, KC will be equal, both to one another and to those two HD, AO. And so, since the two sides AO, AH are equal to the two sides DH, DK, and contain equal angles — namely right angles — [Margin: d — 4.pri. (Elem. I.4)] the bases HK, HO will also be equal. In the same way KM, MO will be shown equal both to one another and to the two HK, HO. Therefore the figure HKMO is equilateral. I say it is also right-angled.

For since the sides HK, KM, MO, OH are equal, [Margin: e — 28.tertij (Elem. III.28)] the four arcs they subtend will also be equal, and hence will be quadrants. Therefore OHK, HKM, KMO, MOH are semicircles, [Margin: f — 31.ter. (Elem. III.31)] and so the four angles H, K, M, O in those semicircles will be right. Therefore HKMO is a square, and hence equal to the square that was found, since the same circle circumscribes both. For the circle HKMO was described with a radius equal to the semidiameter of the circle circumscribed about the square that was found. Which is what was proposed.

Diagram. Above the circle stand the two given lines: F (the shorter segment) and E (the longer, tick-marked segment) — the terms of the ratio $E : F$. Below them, a circle with two inscribed squares (illustrating Proposition XVII): the axis-aligned square ABCD and the rotated square HKMO, with center G and the feet Q, R of perpendiculars from G.

- A (top-left), D (top-right), C (bottom-right), B (bottom-left): corners of the axis-aligned inscribed square ABCD
- H, K, M, O: corners of the rotated inscribed square HKMO (H top, K right, M bottom, O left)

- I (top, between H and D), L (right, between K and C), N (bottom, between M and B), P (left, between O and A): the four intermediate points left "in the middle"
- Q (upper interior): foot of perpendicular from G to AD
- R (left interior): foot of perpendicular from G to AB
- G (center): center of the square and circle

XVIII.

If at the endpoints of a circle's diameter two perpendiculars are erected, and from those same endpoints, through one and the same point of the circumference, two other straight lines are drawn cutting the circle and meeting the two perpendiculars: then the rectangle contained by either of the secants and its interior segment will be equal to the square on the diameter.

This proposition is Cardano's [Girolamo Cardano], from Book 16 of *De Subtilitate*, chapter 1 — as is the one that follows. Both were demonstrated by Giovanni Battista Benedetti [Io. Baptista Benedictus]. Let ABC be a circle whose diameter is BC. At B and C erect two perpendiculars BD, CE; and through any point A taken on the circumference, let the lines BA, CA — drawn from those same points B, C — cut the perpendiculars at E and D. I say that both the rectangle under EB, BA and the rectangle under DC, CA are equal to the square on the diameter BC.

For since in the right triangle BCE the perpendicular CA has been dropped from the right angle C to the base BE — [Margin: a — 31.ter. (Elem. III.31)] because the angle BAC, being in a semicircle, is right — then by the corollary to Proposition 8 of this book [Elem. VI.8] BC is the mean proportional between EB and BA.

[Margin: b — 17.sexti (Elem. VI.17)] Hence the rectangle under the extremes EB, BA will be equal to the square on the mean BC. By the same reasoning the rectangle under DC, CA will be equal to the same square, because BC is also the mean proportional between DC and CA, by the same corollary to Proposition 8 of this book [Elem. VI.8]. Thus what is proposed is established.

Diagram. A circle on diameter BC with perpendiculars erected at its ends, illustrating Proposition XVIII.

- B (bottom-left): endpoint of the diameter
- C (bottom-right): endpoint of the diameter (the right angle of triangle BCE)
- A (on the upper circumference): the assumed point

- D (upper-left): where line CA meets the perpendicular BD (top of the perpendicular at B)
- E (upper-right, tall): where line BA meets the perpendicular CE (top of the perpendicular at C)

XIX.

If in a circle two diameters cut each other at right angles, and from the endpoint of one of them a straight line is drawn cutting the circumference at will and cutting the other diameter — whether that diameter is produced or not — then the rectangle contained by the two segments of this drawn line (one segment lying between the endpoint of the first diameter and the second diameter, the other between that same endpoint and the circumference) will be equal to the square described within the circle.

In the circle ABCD with center E, let the two diameters AC, BD cut each other at right angles, and from the point D draw a line DF at will, cutting the diameter AC at F and the circumference at G. I say that the rectangle under FD, DG is equal to the square described within the circle.

For when the lines DC, CG are drawn, the triangles DCF and DCG will be equiangular with each other. For the angle CDF is common, and the angle DCF is equal to the angle DGC; [Margin: a — 32.pri. (Elem. I.32)] and hence the remaining angle DFC is equal to the remaining angle DCG. That the angles DCF, DGC are equal we shall show thus. If the point F is inside the circle, [Margin: b — 27.ter. (Elem. III.27)] the angles DCF, DGC, standing on the equal quadrants AD, DC, will be equal. But if the point F is outside the circle, then, the line AD having been drawn, [Margin: c — 27.ter. (Elem. III.27)] the angles DAC, DCA, standing on quadrants, will be equal. [Margin: d — 22.ter. (Elem. III.22)] But both DAC and DGC, [Margin: e — 13.pri. (Elem. I.13)] and likewise DCA and DCF, are equal to two right angles; therefore, when the equals DAC, DCA are taken away, the remainders DGC, DCF will also be equal.

For this reason, since the triangles DCF, DCG are equiangular, [Margin: f — 4.sexti (Elem. VI.4)] DF will be to DC as DC is to DG — that is, the three lines DF, DC, DG will be in continued proportion. [Margin: g — 17.sexti (Elem. VI.17)] Therefore the rectangle under the extremes DF, DG is equal to the square on the mean DC — that is, to the square described within the circle, since DC is the side of the square inscribed in the circle, as is evident from Proposition 6 of Book 4 [Elem. IV.6]. Which is what was proposed.

Alternatively. Draw the line BG. [Margin: h — 31.ter. (Elem. III.31)] The angle BGD, being in a semicircle, will be right; and therefore the two triangles BGD, DEF — since they have the right angles BGD, DEF and share the common angle BDG (or EDF) — [Margin: i — 32.pri. (Elem. I.32)] will be equiangular. [Margin: k — 4.sex. (Elem. VI.4)] Therefore DF is to DE as DB is to DG; [Margin: l — 16.sex. (Elem. VI.16)] so the rectangle under DF, DG will be equal to the rectangle under DB, DE. [Margin: m — 17.sex. (Elem. VI.17)] But equal to the rectangle under DB, DE

is the square on the line AD — that is, the square inscribed in the circle — because, by the corollary to Proposition 8 of this book [Elem. VI.8], AD is the mean proportional between DB and DE, as is evident if the line AB is drawn. [Margin: n — 31.ter. (Elem. III.31)] For a right triangle BAD will be formed, and from the right angle the perpendicular AE will be dropped. Therefore the rectangle under DF, DG will also be equal to that same square on the line AD. Which is what was proposed.

Diagram. A circle with two diameters meeting at right angles at the center, illustrating Proposition XIX and its alternative proof. Because two demonstrations share the figure, the auxiliary points F and G each appear at two positions (one for the main proof, one for the *Aliter*).

- A (top): endpoint of the vertical diameter
- C (bottom): endpoint of the vertical diameter
- B (left): endpoint of the horizontal diameter
- D (right): endpoint of the horizontal diameter (source of line DF)
- E (center): intersection of the diameters
- F (interior, below E; and a second position lower down): where the drawn line cuts diameter AC
- G (left, on the circumference; and a second position lower): where the drawn line cuts the circumference

More universally, this may be stated as follows:

If in a circle a perpendicular is erected to the diameter from any point of the diameter, and to this perpendicular two straight lines are drawn from one of the endpoints of the diameter — one to the perpendicular's intersection with the circumference, the other at will, cutting the circumference at another point — then the rectangle under the segments of this latter line (of which one lies between the said endpoint and the perpendicular, the other between the same endpoint and the

circumference) will be equal to the square on the former line, intercepted between the same endpoint and the circumference (or the perpendicular).

In the circle ABCD, let EF be perpendicular to the diameter BD, cutting the circumference at C; and join the lines DC, DF, the latter of which cuts the perpendicular EF at F and the circumference at G. I say that the rectangle under DF, DG is equal to the square on DC. For when the line BG is drawn, the triangles BGD, FDE will be equiangular, because of the right angles at G and E and the common angle FDE. [Margin: o — 4.sex. (Elem. VI.4)] Therefore FD is to DE as BD is to DG. [Margin: p — 16.sex. (Elem. VI.16)] Hence the rectangle under FD, DG will be equal to the rectangle under DE, BD. [Margin: q — 17.sex. (Elem. VI.17)] But this is equal to the square on DC, since — by the corollary to Proposition 8 of this book [Elem. VI.8] — DC is the mean proportional between BD and DE, because, the line BC being drawn, [Margin: r — 31.tertij (Elem. III.31)] the angle BCD would be right, being in a semicircle. Therefore the rectangle under FD, DG will also be equal to the square on DC. Which is what was proposed.

Diagram. A circle with the diameter BD, a perpendicular EF, and the lines DC, DF, illustrating the universal version of the theorem.

- A (top of circle): endpoint of the vertical diameter
- B (left): endpoint of the diameter BD
- D (right): endpoint of the diameter BD
- E (on BD, interior): foot of the perpendicular on the diameter
- C (lower-left, on the circumference): where the perpendicular meets the circumference
- F (interior, on the perpendicular EF): where line DF cuts the perpendicular
- G (lower, on the circumference): where line DF cuts the circumference

COROLLARIVM.

Hence it follows that the former line DC is the mean proportional between the segments FD, DG of the latter line — one of which lies between the endpoint D and the perpendicular, the other between the same endpoint and the circumference.

XX.

Given a circle and two points — whether outside the circle or inside, provided neither lies on the circumference — to draw through these two

points two straight lines to some one point of the circumference, in such a way that the straight line joining the two points at which those two lines cut the circumference is parallel to the straight line connecting the two given points.

This problem — no less subtle than curious — Pappus [Pappus of Alexandria] distributed among three propositions; reducing it to one, we shall demonstrate it much more clearly. Let ABCD be the circle, and first let the two given points E, F be outside the circle, joined by the straight line EF. If, then, straight lines are to be drawn from E and F to some point of the concave (near) circumference, and so on, we shall proceed thus.

From E draw the line EB tangent to the circle at B, and find a third proportional to the two lines EF, EB; let EG be equal to it. Let the point G fall first between E and F — which happens when EF is greater than EB. Then draw GC tangent to the circle at C, on the side toward the earlier tangent EB; from E, through C, draw a line cutting the concave circumference at A; and join AF, cutting the circumference at D. I say that the drawn line CD is parallel to EF.

For since the three lines EF, EB, EG are in continued proportion, [Margin: a — 17.sex. (Elem. VI.17)] the rectangle under EF, EG will be equal to the square on EB. [Margin: b — 36.ter. (Elem. III.36)] But equal to the same square on EB is the rectangle under EA, EC; therefore the rectangle under EF, EG will be equal to the rectangle under EA, EC. And consequently, by the scholium to Proposition 36 of Book 3 [Elem. III.36], a circle can be described through the four points A, C, G, F. [Margin: c — 22.ter. (Elem. III.22)] Therefore the two opposite angles CAF, CGF of the quadrilateral ACGF, described within that circle, are equal to two right angles; [Margin: d — 13.pri. (Elem. I.13)] and the angles CGF, CGE are likewise equal to two right angles. So, taking away the common angle CGF, the remaining angle CGE will be equal to the remaining angle A [i.e., CAF]. [Margin: e — 32.ter. (Elem. III.32)] Moreover the angle DCG is equal to the angle A in the alternate segment. Therefore the angles DCG, CGE will be equal to each other; and since they are alternate angles, [Margin: f — 27.pri. (Elem. I.27)] the lines CD, EF will be parallel. Which is what was proposed.

Diagram. A circle ABCD with two external points E, F and the tangent/secant construction, illustrating the first case of Proposition XX (G between E and F).

- A (top, on the circumference): where the secant from E cuts the far circumference
- B (left, on the circumference): tangent point of EB

- C (interior-left, on the circumference): tangent point of GC
- D (right, on the circumference): where AF cuts the circumference
- E (bottom-left, external): given point
- G (bottom-center, on line EF): third-proportional point
- F (bottom-right, external): given point

Next, let the point G fall on the point F — which happens when EF is equal to BE. Then again draw GC tangent to the circle at C, on the side toward the earlier tangent EB; from E, through C, draw a line cutting the concave circumference at A; and join AF, cutting the circumference at D. Again I say that the drawn line CD is parallel to EF.

For since EB, EF are equal, [Margin: g — 36.ter. (Elem. III.36)] and the rectangle under AE, EC is equal to the square on EB, this same rectangle will also be equal to the square on EF. Hence [Margin: h — 5.quar. (Elem. IV.5)] if a circle is described about the triangle ACF — since the line EA cuts it, while the line EF is applied to it — [Margin: i — 37.ter. (Elem. III.37)] the line EF will be tangent to that circle. [Margin: k — 32.ter. (Elem. III.32)] Therefore the angle EFC will be equal to the angle A in the alternate segment of that circle; [Margin: l — 32.ter. (Elem. III.32)] and the angle FCD is likewise equal to that same angle A in the alternate segment of the circle ABCD. Therefore the angles EFC, FCD will be equal to each other; and since they are alternate, [Margin: m — 27.pri. (Elem. I.27)] the lines CD, EF will be parallel. Which is what was proposed.

Diagram. A circle ABCD with two external points E, F and the tangent/secant construction, illustrating the further cases of Proposition XX (G coinciding with F, and G beyond F).

- A (top, on the circumference): where the secant from E cuts the far circumference
- B (left, on the circumference): tangent point of EB
- C (interior-center, on the circumference): tangent point of GC
- D (right, on the circumference): where AF cuts the circumference
- E (bottom-left, external): given point
- G (bottom, near F): third-proportional point
- F (bottom-right, external): given point

Thirdly, let the point G fall beyond F — which occurs when EF is less than EB. With the same construction made, since the three lines EF, EB, EG are in continued proportion, [Margin: n — 17.sex. (Elem. VI.17)] the rectangle under EF,

EG will be equal to the square on EB. [Margin: o — 36.ter. (Elem. III.36)] But equal to the same square on EB is the rectangle under AE, EC. Therefore the rectangle under EF, EG — that is, under EG, EF — will be equal to the rectangle under EA, EC; and consequently, by the scholium to Proposition 36 of Book 3 [Elem. III.36], a circle can be described through the four points A, C, F, G. [Margin: p — 21.ter. (Elem. III.21)] Therefore the two angles A, G, in the same segment CAGF of that circle (whose chord would be the drawn line CF), [are equal] to each other...

will be equal to one another. [Margin: q — Elements III.32] And the angle GCD equals the angle A, which lies in the alternate segment of the given circle ABCD. Therefore the angle GCD will also equal the angle G; and since these two are alternate angles, [Margin: r — Elements I.27] CD and EF will be parallel. Which was to be proved.

But if from the very start a line tangent to the circle had been drawn from the point F, and the rest were carried out as before, the very same point A would be found — for no other point can solve the problem. To see this, imagine any other point H near A, between A and D. (If you mark that point H in ink, the demonstration will be easier; and let the same be understood of other points H to be conceived mentally, and likewise of the point I in the last figure.) Then the line FH will cut the circle above D, whereas the line EH will cut it below C; and so the straight line joining the two points of section will cut CD. Produced, therefore, it will also cut the line parallel to CD, namely EF — and hence it cannot be parallel to EF itself. The contrary happens if the point H is taken between A and C: for then the line FH falls below D, and EH above C, and so on.

But suppose that from the same given points E and F two straight lines are to be drawn to some point on the convex circumference, such that, when produced, they cut the concave part of the circumference in two points, and so that the line passing through those two points is parallel to the line joining E and F. We shall proceed as follows. Draw EB tangent to the circle at B, and to the two lines EF and EB find a third proportional EG; let the point G first fall between E and F. Then from G draw GD tangent to the circle at D — but not on the side toward the earlier tangent EB — and draw ED, cutting the circumference at the point C; through C project a line from F, cutting the circumference at A. I say that the line AD so drawn is parallel to EF. For since the three lines EF, EB, EG are in continued proportion, [Margin: s — Elements VI.17] the rectangle under EF, EG equals the square on EB. But the rectangle under ED, EC also equals that same square on EB. [Margin: t — Elements III.36] Therefore the rectangles under EF, EG and under ED, EC are equal to one another; and consequently, by the scholium to III.36, a

circle can be described through the four points C, D, F, G. [Margin: u — Elements III.21] So the two angles CDG and F, lying in the same segment CDFG of that circle (whose chord would be the line GC), are equal to one another. But the angle CDG equals the angle A, in the alternate segment of the given circle ABCD. [Margin: x — Elements III.32] Therefore the angle F too will equal the angle A alternately, [Margin: y — Elements I.27] and so AD and EF are parallel. Which was to be proved.

Next, let the point G fall on F. Again draw GD tangent to the circle at D — not, however, on the side toward the earlier tangent EB — and draw ED, cutting the circumference at the point C; through C let a line drawn from F cut the circumference at A. I say that the line AD so drawn is parallel to EF. For since EB and EF are equal — which comes about because EF is to EB as EB is to EF [that is, to EG] — the squares on them will be equal. But the rectangle under ED, EC equals the square on EB, and therefore also the square on EF. So, since [Margin: z — Elements IV.5] if a circle be circumscribed about the triangle CDF the line ED cuts it, while EF is applied to it, [Margin: a — Elements III.37] EF will be tangent to that circle. [Margin: b — Elements III.32] Therefore the angle EFC equals the angle FDE, in the alternate segment of that circle. But the angle FDE equals the angle A, in the alternate segment of the circle ABCD. [Margin: c — Elements III.32] Therefore the angle EFC too will equal that same angle A alternately; hence AD and EF are parallel. [Margin: d — Elements I.27] Which was to be proved.

Thirdly, let the point G fall beyond F. With the same construction made, since the three lines EF, EB, EG are in continued proportion, [Margin: e — Elements VI.17] the rectangle under EF, EG (or under EG, EF) equals the square on EB. But the rectangle under ED, EC is also equal to that same square. [Margin: f — Elements III.36] Therefore the rectangle under EG, EF equals the rectangle under ED, EC; and so, by the scholium to III.36, a circle can be described through the four points C, D, G, F. [Margin: g — Elements III.22] So the two angles EDG and CFG, opposite in the quadrilateral CDGF inscribed in that circle, together equal two right angles, and hence equal the two angles at F, [Margin: h — Elements I.13] which likewise equal two right angles. Taking away the common angle CFG, the remaining angle CDG equals the remaining angle CFE. [Margin: i — Elements III.32] But the angle GDC equals the angle A, in the alternate segment of the given circle ABCD. Therefore the angle CFE too will equal that same angle CAD alternately, [Margin: k — Elements I.27] and for that reason AD and EF are parallel. Which was to be proved.

But if from the start a line tangent to the circle were drawn from F, and the rest were carried out as before, the very same point C would be found, since no other point can accomplish the problem. For let there be any other point H near C, conceived in the mind between A and C: then the line FH will fall below A, and the line EH above D. So the straight line joining the points of section will cut AD, and consequently, as was said above, it cannot be parallel to EF itself. If the point H were taken between D and C, the line FH would fall above A, and the line EH below D, and so on.

But now let the points E and F be given inside the circle ABCD. Draw AG through E arbitrarily, and to the three lines EF, EA, EG find a fourth proportional, and let EH equal it (H will necessarily fall outside the circle). [Margin: l — Elements VI.16] For since the rectangle under AE, EG — the second and third — equals the rectangle under EF, EH — the first and fourth — a circle can be described about the four points A, F, G, H, by the scholium to III.35, cutting the circle ABCD at A and G. Then, since the arc of that circle through F lies inside this circle, the other arc, through H, will lie outside; [Margin: m — Elements III.10 [?]] for a circle cuts a circle in only two points, and hence the circle drawn through A, F, G, after the points A and G, falls outside the circle; and so the point H, lying on that circle, will fall outside the circle. Now draw HB tangent to the circle at B.

Diagram. A circle with two points marked on it, and three collinear points on a base line below; secant and tangent lines connect them. Readable labels:

- B (on the circle, left): tangent point
- A (on the circle, upper right): point where the projected secant meets the circumference
- C (lower interior, left of center): a point of section
- D (lower interior, right of center): tangent point
- E (base line, far left)
- F (base line, center-right)
- G (base line, right)

[Positions read on the leaf; the internal line-connections are not all separately resolvable.]

Diagram. Circle with a quadrilateral-and-secants construction (case with G between E and F). Readable labels:

- A (on the circle, upper left)
- D (on the circle, upper right)

- C (center interior)
- E (base line, left)
- G (base line, center)
- F (base line, right)

Diagram. Circle with inscribed lines (case with G falling on F). Readable labels:

- B (on the circle, upper left)
- A (on the circle, left)
- D (on the circle, right)
- C (center interior)
- F (base line, left) [the lower-right base labels read as "F" and "G" together and are not cleanly separable [?]]

Diagram. Circle with inscribed lines (case with G beyond F). Readable labels:

- A (on the circle, upper left; a mark, apparently "P", stands just above it [?])
- D (on the circle, upper right)
- C (center interior)
- E (base line, left)
- F (base line, center)
- G (base line, right)

Diagram. Circle with an interior star of secants (the case where E and F lie inside the circle, with the tangent point H). Readable labels:

- A (on the circle, upper left)
- H (top of the figure)
- E (interior, center)
- F (interior, right of E)
- B (lower left)
- G (base, center-bottom)
- C (lower right)

Diagram. A second circle for the interior-points case, with an external point H at the left. Readable labels:

- A and D (near the top, close together)
- H (far left)
- E and F (upper-center interior)

- B (lower left)
- G (just below B)
- C (lower right)

For draw a line from B through E, cutting the circumference at D, and from D through F a line cutting the circumference at C: I say that the line BC so drawn is parallel to EF. For since EF is to EA as EG is to EH, [Margin: n — Elements VI.16] the rectangle under EF, EH equals the rectangle under EA, EG. But the rectangle under EA, EG equals the rectangle under ED, EB. [Margin: o — Elements III.35] Therefore the rectangle under EF, EH equals that same rectangle under ED, EB; and so, by the scholium to III.35, a circle can be described about the four points B, H, D, F. [Margin: p — Elements III.21] Hence the two angles HBD and DFH, lying in the same segment DFBH of that circle (whose chord would be the line DH), are equal. But the angle HBD equals the angle C, in the alternate segment of the given circle ABCD. [Margin: q — Elements III.32] Therefore the angle DFH too will equal that same angle C — the exterior [equal to] the interior. [Margin: r — Elements I.28] So the lines BC and EF are parallel. Which was to be proved.

But if it happens that the tangent HB falls on the point G, there is no need to draw another line BD; rather AG, drawn at the outset, will conclude the proposition, as is clear in the second figure.

Now if the solution of the problem were to begin from the point F rather than from E, the very same point D would be found — for the problem can be accomplished by no other point. For if any other point I be taken near D, between D and C, the line FI will fall below C and EI above B. So the straight line joining the points of section will cut BC, and therefore, as was said above, it will not be parallel to EF. If the point I were taken between D and B, the line FI would fall above C and EI below B, and so on.

On the Marvelous Nature of a Certain Curved Line, by which a Figure of any Number of Equal Sides is Inscribed in a Circle, the Circle is Squared, and Many Other Things Most Delightful to Know are Accomplished

Perhaps last year I came upon Book 4 of Pappus of Alexandria, where he explains a certain curved line which — as he reports Dinostratus, Nicomedes, and some more recent geometers devised for the squaring of the circle — was for that office called by them τετραγωνίζουσα [Greek: tetragōnizousa, "the squaring [line]"]; for the same reason we shall call it the Quadratrix. Now although the authors just

named try to describe a line of this kind by two imaginary motions of two straight lines — in doing which they beg the very principle at issue, so that Pappus rejects it as useless and as one that cannot be described — we shall nonetheless describe it geometrically, without those motions, by finding as many of the points through which it must pass as we please, just as is customarily done in describing the conic sections. We judged that this discovery should be appended, in place of an epilogue, to this sixth book, because by the help of this line geometrical problems most pleasant to know, and sought after to this very day, are accomplished with the greatest ease. This we had undertaken, at the end of Book 4, to do here, while deferring a fuller treatment of the quadrature to our *Practical Geometry*. So, then, the description of the Quadratrix line will run as follows.

In the square ABCD let the quadrant BD be described. Suppose, as the inventors of the Quadratrix wish, that the radius AD is carried uniformly about the center A, while the topmost side CD likewise descends uniformly, in such a way that, in the same time in which the point D traverses the circumference DB with an ever-uniform motion, the line DC — also descending with uniform motion — reaches the side AB, yet always staying parallel to AB and making right angles with the sides AD and BC. Then the radius, swept round in the circumference DB, and the line DC, carried downward, will continually cut one another in points which will trace the Quadratrix line — that is, through which the Quadratrix will pass; such is the curved line DE. But because these two uniform motions — one along the circumference DB, the other along the straight lines DA, CB — cannot be produced unless the ratio of a circular line to a straight line be known, Pappus rightly finds fault with this description; for that ratio is as yet unknown, and is the very thing proposed to be investigated by means of this line. We shall therefore describe the same Quadratrix line geometrically, in this way. Let the arc BD be divided into any number of equal parts, and each side AD, BC into the same number of equal parts. The division will be easiest if both the arc DB and each side AD, BC be first bisected, then each half bisected again, and each single part bisected again, and so on as far as one pleases. The more divisions there are, the more accurately the Quadratrix line will be drawn. To avoid confusion, we have divided both the arc DB and the two sides AD, BC into 8 equal parts.

Next, let pairs of points on the sides AD, BC that are equally distant from the side DC (or AB) be joined by hidden straight lines, and from the center A let other hidden straight lines be extended to each of the division-points of the quadrant DB. For where these lines cut the former ones — the first the first, the second the second, and so on — through those points the Quadratrix line is to be drawn

smoothly, so that it is not wavy but always advances evenly, making no hump or angle anywhere: such is the curved line DE, cutting the radius AB at E.

But since the point E on the side AB cannot be found geometrically — because there every intersection of straight lines ceases — in order to find it without notable error (one, that is, that would fall under the senses) we shall use this device. We shall repeatedly bisect the lowest part AF of the side AD, if it is not small enough, until the lowest little part is very small; and in the same way we shall repeatedly bisect the lowest part BI of the arc DB, until as many subdivisions are made as were made in the part AF, so that the little part BK is the same fraction of the whole arc DB as AG is of the whole side AD. Then, equal to the little part AG, we shall cut off BL, BN, AM, and we shall draw the hidden lines GL, MN. Drawing from the center A the hidden line AK, which cuts GL at the point H (to be marked most exactly), we shall take MP equal to GH. For if we continue the Quadratrix, drawn up to H, with an even and uniform exten-

Diagram. The construction of the Quadratrix in the square ABCD with the quadrant BD centered at A. The interior shows the family of radial lines from A and horizontal lines descending from side DC, whose intersections trace the curve; several auxiliary division-points cluster near the base for the "device" described in the text. Readable labels:

- D (top left corner) and C (top right corner)
- A (bottom-left corner / center of the quadrant)
- B (bottom-right corner)
- Down the left side toward the base: F, G, then A, and M (lowest)
- Along the base near the center: H, E, P
- Down the right side toward the base: I, K, L, then B, and N

[The dotted radial lines from A and the horizontal dashed lines are the construction lines; individual division-points beyond those lettered are not separately labelled.]

extension as far as P, the Quadratrix line will cut the side AB at E, the point sought. For, because of the small distance between the lines GH, AE, MP, they turn out to be nearly equal — although, geometrically speaking, the line AE is always somewhat greater, however little those lines are apart; but that excess cannot be detected with compasses. The same happens on the circumference of the circle: the lines GL, AB, MN, if they lie little apart, will be judged wholly equal within the circle, although in truth AB is somewhat greater. And so, if those three lines GH, AE, MP have a very small distance between them, there can be no doubt that the

point E — where the Quadratrix line cuts the radius AB — does not differ from the one that truly lies on the Quadratrix there, provided the points H and P have been found exactly and with the greatest diligence.

Furthermore, we shall call the line AD the *side* of the Quadratrix, the line AE its *base*, and finally the point A its *center*.

But we shall find the points of the Quadratrix near the base more reliably, without intersections of lines, in this way. Draw the chord BQ in the quadrant, and bisect it at D. This will be done if from A to C, the midpoint of the quadrant, the line AC be drawn; for by the scholium to III.26 this will bisect the line BQ. Then let AD be taken equal to AE, and joining DE, let it be bisected at F — which will also be done if from A to I, the midpoint of the arc BC, the line AI be drawn; for this (if drawn) would bisect the chord BC, by the scholium to III.27, and consequently also the line DE, by the scholium to Proposition 4 of this [book], [Margin: a — Elements VI.2] since it is parallel to the chord BC — because the sides AB, AC are cut proportionally at D, E, seeing that AB and AC are equal, and so are AE and AD. Again, let AG be taken equal to AF, and joining FG, let it be bisected at H — which will also be done by the line AK drawn to K, the midpoint of the arc BI. And in this way, if AH be taken equal [to AI], and the rest done as before, another point will be found between H and G. And so, one after another, we shall find as many other points as we please nearer to AB, by perpendicular lines and not by oblique sections. [Margin: b — Elements III.3] For AD is perpendicular to QB, AF to DE, AH to FG, and so on. Now all these points found — D, F, H, and so on — lie on the Quadratrix, which I show as follows. Draw DL, FM, HN parallel to AB, cutting DB at O, P. [Margin: c — Elements VI.2] Then, as DB is to DQ, so [will AL be to LQ] [?]; and therefore AQ too will be bisected at L. But the arc BQ is also bisected at C. Therefore, as has been shown, the point D lies on the Quadratrix. Again, since DE is bisected at F, [Margin: d — Elements VI.2] DB too will be bisected at O; [Margin: e — Elements VI.2] and so, as FG is to FD, so is BO to OD. But as BO is to OD, so is AM to ML; and as EF is to FD, so is the arc BI to IC — since in both cases the ratio is one of equality. Therefore also, as AM is to ML, so is BI to IC. So, as we have shown, AI and MO cut one another at a point of the Quadratrix. And the same reasoning holds for the other points found by this art.

Diagram. A quadrant with center A and the auxiliary construction for finding points of the Quadratrix near the base by successive chords and bisections.

Readable labels:

- Q (top of the arc)
- C (on the arc, upper right)

- D (interior, below C; foot of the first chord-bisection)
- I (on the arc, right)
- Down the left side: L, M, N
- Interior, center-low: F, O
- Along the base: A (bottom-left corner), G, E, B (bottom-right); H and P near the center of the base; K to the right, near B

[The dashed lines are the hidden auxiliary lines (chords, radii, and parallels) named in the text.]

It is clear that this curved line DE, described by us point-by-point, is geometrically the very same as the one that Dinostratus and Nicomedes conceived as described by those two imaginary motions. For if the radius AD, about the center A, be moved through the arc DB with uniform motion, in the same time in which the side DC is carried downward, likewise with uniform motion, then when the radius AD has passed over any part whatever of the arc DB, the side DC will have traversed a like part of the sides DA, CB — otherwise either those two motions would not be uniform, or the radius AD and the side DC would not reach the side AB in the same time. Since, then, the lines drawn from the center A through the parts of the arc DB always cut off, from the arc DB and from the sides DA, CB, like parts, by construction, it plainly follows that the points of the curved line DE, found by us geometrically, do not differ from the points that would be found by those two motions. This, then, is the description of the Quadratrix line, which may in a sense be called geometrical — just as the descriptions of the conic sections, which are also made point-by-point, as handed down by Apollonius, are called geometrical, even though they are more liable to error than our description, on account of the finding of the many mean proportional lines needed for those descriptions, of which there is no need in describing the Quadratrix. Therefore, unless one is willing to reject as useless and non-geometrical the whole doctrine of the conic sections — which Apollonius of Perga pursued with such keenness of intellect that for it he was called the Great Geometer (a thing I judge no one will do, since the most excellent geometers have employed the conic sections for their demonstrations; for Menaechmus used the hyperbola and the parabola in finding two mean proportional lines between any two given straight lines, Archimedes himself proved many splendid things about these same conic sections, and finally such sections have a notable use in gnomonics, as appears from our *Gnomonica*) — one will be wholly compelled to admit that this our description of the Quadratrix line is in a sense geometrical. Add to this that the conchoid, by which Nicomedes most acutely investigates two mean proportional lines, is likewise described point-by-point, as we shall say in

our book *On Measurements*. But let us now set out the use of the Quadratrix line in a few propositions.

I.

If from the center, through any points of the Quadratrix line, straight lines be drawn as far as the circumference of the quadrant described from the same center, and from the same points perpendiculars be dropped to the base, and other straight lines be drawn parallel to that base: then the arcs of the quadrant intercepted between the radii will be proportional to the perpendiculars, or to the segments of the radius lying between the parallels.

From the center A, through points F, K taken anywhere on the Quadratrix, draw straight lines meeting the arc of the quadrant at H, L; drop the perpendiculars FG, KM to the base AE; and draw FI, KN parallel to that base AE. I say that as the whole arc DB is to the arc HB, so is the whole side DA to the perpendicular FG, or to the segment IA, and so on. For since the arc DH is the same fraction of the whole arc DB as the line DI is of the whole side DA — as is clear from the description of the Quadratrix line, whether it be thought of as described by those two proportional motions of Dinostratus and Nicomedes, or by the method that we have pre-

that we have prescribed. For in that curve the arc DH always comprehends as many small parts of the whole arc DB as the line DI contains parts of the whole side DA — because the straight lines AH and IF intersect at the point F of the Quadratrix. Nor is this proportionality impaired even if the arc DH is incommensurable with the whole arc DB, and the line DI incommensurable with the whole side DA, since the Quadratrix advances with perpetual uniformity through all its points. For suppose the line DI were *not* such a part of the whole side DA — whether commensurable or incommensurable — as the arc DH is of the whole arc DB. Then, if one imagined such a part, smaller than DI or larger, the parallel drawn through its endpoint would cut the straight line AH either above F or below it, at a point through which the Quadratrix would have to be described; and so the curve would not pass through F — which is absurd and contrary to the hypothesis. Since, I say, the arc DH is the same part of the whole arc DB as the line DI is of the whole side DA, the remaining arc HB will likewise be the same part of the whole arc DB as the remaining line IA is of the whole side DA. Hence it will follow that, as the whole arc DB is to the arc HB, so the whole side DA is to the line IA — that is, to the line

FG, [Margin: a — *Elements* I.34] which is equal to IA. And therefore, both by *dividendo* (separation): as the arc DH is to the arc HB, so is the line DI to the line IA, or FG; and by *convertendo* (conversion): as the arc HB is to the arc DB, so is the line FG, or IA, to the line DA, and so on.

By the same reasoning it will be: as the arc DB is to the arc LB, so is the line DA to the line NA, or to KM, [Margin: b — *Elements* I.34] which is equal to NA. And: as the arc DL is to the arc LB, so is the line DN to the line NA, or KM. And: as the arc LB is to the arc DB, so is the line KM, or NA, to the line DA. Since therefore, as LB is to DB, so KM is to DA; and as DB is to HB, so DA is to FG; it will follow, *ex aequo*: as LB is to HB, so KM is to FG. And by conversion: as HB is to LB, so FG is to KM — that is, so IA is to NA. And by separation: as HL is to LB, so IN is to NA, or FQ is to QG.

Again, since as DH is to HB, so DI is to IA; and as HB is to LB, so IA is to NA; it will follow, *ex aequo*: as DH is to LB, so DI is to NA, or to KM. Therefore the arcs intercepted between the radii are always proportional to the perpendiculars, or to the segments of the radius placed between the parallels. Which was to be proved.

Diagram. The Quadratrix figure: a square with corners D (top left), C (top right), B (bottom right), and A (bottom left), the last being the center. A quadrant arc runs from D to B, and the Quadratrix curve runs from D down to E on the base. Two radii from A meet the arc at H (upper) and L (lower), crossing the Quadratrix at F and K respectively; from F and K the perpendiculars FG and KM drop to the base, and the parallels FI and KN run to the side DA.

- D (top-left corner): upper end of quadratrix and of side DA
- C (top-right corner)
- B (bottom-right corner): far end of quadrant arc
- A (bottom-left corner): center of the quadrant
- H (on the arc, upper): endpoint of radius AH
- F (on the quadratrix, on radius AH): FI parallel to base, FG perpendicular to base
- I (on side DA): foot of parallel FI
- L (on the arc, lower): endpoint of radius AL
- K (on the quadratrix, on radius AL): KN parallel to base, KM perpendicular to base
- N (on side DA): foot of parallel KN

- Q (interior, intersection near center): intersection of FG with the parallel KN
- G (on the base): foot of perpendicular FG
- M (on the base): foot of perpendicular KM
- E (on the base): foot of the quadratrix

II.

To divide a given arc of a circle in a given ratio.

First, let the arc HB in the preceding figure be the one to be divided, in the given ratio of the line O to the line P. Through the point H draw to the center A the straight line HA, cutting the Quadratrix at F, and draw FI parallel to the base AE. Then let the line IA be cut at N — by the scholium of Proposition 10 of this book — so that IN is to NA as O is to P; and, drawing NK parallel to the base AE, cutting the Quadratrix at K, let a straight line be sent out from the center A through K, cutting the arc HB at L. I say that the arc HB has been cut at L in the given ratio of O to P. For since, as we showed in Proposition 1, HL is to LB as IN is to NA; and IN is to NA, by construction, as O is to P; [Margin: a — *Elements* V.11] HL will also be to LB as O is to P.

The three given ratios are represented by these drawn line-segments, with their assigned lengths:

- O ——— 3
- P ——— 2
- R ——— 3
- S ——— 5
- T ——— 8
- V ——— 2

Next, let the whole quadrant DB be cut in the ratio R to S. The radius DA being divided at I so that DI is to IA as R is to S, draw IF parallel to AE, cutting the Quadratrix at F. Then, the straight line AFH being drawn, it will be, by Proposition 1, that DH is to HB as DI is to IA — that is, as R is to S.

Thirdly, let the same quadrant DB be cut into two arcs, so that the whole quadrant has to one of them the given ratio T to V. With the three lines T, V, DA, let a fourth proportional be found, and let AN be cut off equal to it. Then, drawing NK parallel to AE, cutting the Quadratrix at K, draw from A through K the straight

line AKL. I say that the quadrant has been cut at L as proposed. For it is, by Proposition 1, that DB is to LB as DA is to NA — that is, as T is to V.

Fourthly, let the semicircle ABC be divided in a given ratio, namely a triple one. Let each quadrant AB, BC be cut according to the given triple ratio at E and F, and let the arc EG be cut off equal to the arc AE, or BF. Then if from the common arc ABC equal parts are taken away — namely the two arcs AE, BF together, and the arc AG — the remainders will become equal, namely the two arcs EB, FC together, and the arc GC. And since, as AE is to EB, so BF is to FC, [Margin: b — *Elements* V.12] the arcs AE, BF together will be to the arcs EB, FC together — that is, the arc AG to the arc GC — as AE is to EB. But AE has to EB the given triple ratio. Therefore the arc AG will also have to the arc GC the same given ratio.

Fifthly, let the arc ACD, containing three quadrants, be cut in the same ratio. The three quadrants AB, BC, CD being divided in that ratio at E, F, H, let the arc EG be taken equal to BF, and the arc GI equal to CH. Then if from the common arc ACD equal parts are taken away — namely the three arcs AE, BF, CH together, and the arc ABI — the remainders will become equal, namely the three arcs EB, FC, HD together, and the arc ID. And since the three arcs AE, BF, CH have to the three arcs EB, FC, HD the same ratio, [Margin: c — *Elements* V.12] all three together will have to all three together — that is, the arc ABI to the arc ID — the same ratio that the single arc AE has to the single arc EB, namely the given one.

Lastly, let the arc ACK be divided in the same way. The three quadrants being again divided, together with the arc DK, as proposed, at E, F, H, L, let the arc EG be taken equal to BF, the arc GI equal to CH, and the arc IM equal to DL. Then if from the common arc ACK equal parts are taken away — namely the four arcs AE, BF, CH, DL together, and the arc ABM — the remainders will become equal, namely the four arcs EB, FC, HD, LK together, and the arc MK. And since the four arcs AE, BF, CH, DL have to the four arcs EB, FC, HD, LK

the same ratio, [Margin: d — *Elements* V.12] all four together will have to all four together — that is, the arc ABM to the arc MK — the same ratio that the single arc AE has to the single arc EB, namely the one that was given. Therefore what is proposed is established.

COROLLARIVM.

From these results we easily divide any rectilinear angle into two angles having a given ratio, and moreover any arc, and any angle, into any number of equal parts.

For, once an arc has been described from a given angle, and that arc divided as required, if a straight line be drawn from the angle to the point of division, the angle will be divided in the same way as the arc — [Margin: c — *Elements* VI.33] since, as arc is to arc, so is angle to angle at the center.

But if the arc, or the angle, is to be cut into any number of equal parts, it must be divided into two parts having a multiple ratio denominated by the number that is one less than the number of proposed parts. For example, if the arc BC, or the angle BAC, is to be divided into five equal parts, the arc BC must be cut at G in the quadruple ratio. For GC will be the fifth part of the arc BC; and if from the rest four equal parts GF, FE, ED, DB be cut off, the arc BC will be divided into five equal parts. And if from A the straight lines AG, AF, AE, AD be drawn, the angle BAC will likewise be cut into five equal angles. Which was proposed.

Diagram. A fan-shaped figure: from the apex A a bundle of straight lines fans down to an arc at the bottom. The arc runs from B (left end) through the division-points D, E, F, G to C (right end); rays AD, AE, AF, AG divide the angle at A into equal parts.

- A (apex): vertex of the divided angle
- B (left end of arc)
- D, E, F, G (division points along the arc, left to right)
- C (right end of arc)

III.

To construct an isosceles triangle each of whose equal angles has a given ratio to the remaining angle.

Let the given ratio be that of the line AB to the line BC. Let BC be bisected at D, and, a circle FGH of any size being described from a center E with a diameter FG drawn in it, let the semicircumference FHG be cut at H so that the ratio of the arc FH to the arc HG is the same as that of the line AB to the line BD; and let the lines HE, HG, HF be joined. I say that each of the equal angles of the isosceles triangle EGH at the base GH has to the remaining angle GEH the given ratio AB to BC. For since, as AB is to BD, so is the arc FH to the arc HG; and, as the arc FH is to the arc HG, [Margin: a — *Elements* VI.33] so is the angle EGH [?] to the angle GFH; [Margin: b — *Elements* V.11] it will be: as AB is to BD, so the angle FGH to the angle GFH. But as BD is to BC — the double of BD — so is the angle GFH to the angle GEH, [Margin: c — *Elements* III.20 [?]] which [GEH] is double the angle GFH

[?]. Therefore, *ex aequo*, it will be: as AB is to BC, so is the angle EGH to the angle GEH. Which was proposed.

Diagram. A circle with center E and vertical diameter FG (F at top, G at bottom). On the upper diameter, below F, are the tick-marks C, D, B (marking the reference segments AB, BC, BD). The point H lies on the circle at the lower right; the chords HF and HG, together with the diameter, form the isosceles triangle. A is marked near the bottom, below E toward G.

- F (top of circle): top of diameter
- C, D, B (tick-marks on the diameter below F): reference segments [?]
- E (center of circle)
- A (near the bottom, below the center)
- G (bottom of diameter)
- H (on the circle, lower right): apex of the constructed triangle

COROLLARIVM.

Therefore, if isosceles triangles are constructed in which the angles equal at the base have to the remaining angle ratios that are both multiple-sesquialter and multiple in order, then by the former all equilateral figures with an even number of sides will be described, and by the latter all equilateral figures with an odd number of sides, inscribed in a circle, as we showed at the end of Book 4.

We shall accomplish the same thing without triangles of this kind, if we cut the whole circumference into as many equal parts — as we taught in the immediately preceding corollary — as the figure to be inscribed ought to have sides or angles, and so on.

IV.

If the quadrant and the quadratrix have the same center, then the arc of the quadrant, the radius, and the base of the quadratrix are in continued proportion.

Let there be a quadrant, and a quadratrix described from it, as above. I say that the arc BD, the radius DA, and the base AE of the quadratrix are in continued proportion — that is, that BD is to DA as DA is to AE. If not, let it be that BD is to DA as DA is to AF, [where AF is] greater than AE itself or less; and first let AF be greater than AE. A quadrant FG being described from the center A through F, cutting the quadratrix at H, draw through H the radius AHK, and drop the perpendicular HI. Since, then, the arc BD is posited to be to the line DA as DA —

that is, as AB — is to AF; and since, as AB, the radius, is to the radius AF, so is the arc BD to the arc FG (for since, by the demonstrations of Pappus, as we too shall show in our book *On Measurements*, the diameter is to the diameter as the circumference of a circle is to the circumference of a circle, [Margin: a — *Elements* V.15] the radius AB will also be to the radius AF as the same circumference is to the same circumference, [Margin: b — *Elements* V.15] and hence also as the quarter of the circumference to the quarter of the circumference — that is, as the arc BD to the arc FG): [Margin: c — *Elements* V.11] the arc BD will also be to the line DA as the same arc BD is to the arc FG. [Margin: d — *Elements* V.9] And therefore the line DA and the arc FG will be equal. But since, by Theorem 1, as the arc BD is to the arc BK, so is the line DA to the line HI; and as the arc BD is to the arc BK, so is the arc FG to the arc FH — because the arcs BD, BK are similar to the arcs FG, FH, as was shown above in this scholium: [Margin: e — *Elements* V.11] the line DA will also be to the line HI as the arc FG is to the arc FH. Since, then, the line DA has been shown equal to the arc FG, [Margin: f — *Elements* V.14] the line HI will also be equal to the arc FH — which is absurd. For the line HI is less than the arc FH, since it is the half of the chord subtending an arc double of FH [Margin: g — *Elements* III.3] (for the line AF bisects that chord, and hence also the arc, by the scholium of Proposition 27 of Book 3); and a chord is always less than its arc. Therefore the arc BD is not to the radius DA as DA is to a line greater than the base AE of the quadratrix.

Diagram. The Quadratrix figure (first case of Proposition IV): the square D (top left), C (top right), B (bottom right), A (bottom left), with the quadrant arc from D to B and the quadratrix from D to E on the base. A smaller quadrant arc through F is drawn; the radius AHK cuts the quadratrix at H, with the perpendicular from H falling on the base. G lies on the side DA.

- D (top-left corner)
- C (top-right corner)
- G (on side DA): endpoint of the inner arc
- K (on the quadratrix / arc, upper right): end of radius AHK
- H (interior, intersection): where radius crosses the quadratrix
- A (bottom-left corner): center
- I (on the base): foot of the perpendicular HI
- E (on the base): foot of the quadratrix
- F (on the base): foot of the inner quadrant
- B (bottom-right corner)

Next, if it can be done, let AF be less than AE. A quadrant FG being described from the center A through F, erect from F, to AE, the perpendicular FL, cutting the quadratrix at L — a point through which let the radius ALK be drawn, cutting the arc FG at H. We shall then show, as before, that the arc FG is equal to the line DA; and likewise that the arc BD is to the arc BK — that is, the arc FG to the arc FH — as the line DA is to the line LF. Therefore, since the arc FG has been shown equal to the line DA, the arc FH will also be equal to the line LF. Which is absurd. For the line LF is greater than the arc FH. For if from L there were drawn toward G another straight line tangent to the circle FG, just as LF touches the same circle at F, these tangents would be equal, by the scholium of Proposition 36 of Book 3; and the arc intercepted between them would be bisected at H, because, by the scholium of Proposition 37 of Book 3, the angle contained by them would be bisected, [Margin: h — *Elements* I.4 or I.8] and hence also the angle at the center A, if a straight line were joined to the other point of contact; [Margin: i — *Elements* III.26] and therefore also the arcs on which they stand would be equal. Since, then, by Archimedes at the beginning of *On the Sphere and Cylinder*, those two tangents together are greater than the arc contained by them, their half LF will also be greater than the half FH of that arc. Therefore the arc BD is not to the radius DA as DA is to a line less than the base AE of the quadratrix; nor, as was shown, as DA to a greater line. Therefore it is as DA to the base AE itself. Which was proposed.

Diagram. The Quadratrix figure (second case of Proposition IV): the square D (top left), C (top right), B (bottom right), A (bottom left), with the quadrant arc from D to B and the quadratrix. An inner quadrant through F is drawn; the perpendicular FL rises from the base and cuts the quadratrix at L, through which the radius ALK passes, cutting the inner arc at H. G lies on the side DA.

- D (top-left corner)
- C (top-right corner)
- K (on the quadratrix / arc, upper right): end of radius ALK
- G (on side DA): endpoint of the inner arc
- L (interior): where the perpendicular FL cuts the quadratrix
- H (interior, lower): where radius ALK cuts the inner arc
- A (bottom-left corner): center
- F (on the base): foot of the perpendicular FL and of the inner quadrant
- E (on the base): foot of the quadratrix
- B (bottom-right corner)

COROLLARIVM I.

Hence we shall easily find a straight line equal to any arc of a circle whose quadrant is BD, from which the Quadratrix has been described.

For since the arc BD is to DA as DA is to AE, it will be, by conversion, that AE is to DA as DA is to the arc of the quadrant BD. If, then, for the two lines AE, AD a third proportional be found, [Margin: k — *Elements* V.11] AD will be to that third [line] as it is to the arc BD, since each ratio is the same, namely that of AE to AD.

[Margin: l — *Elements* V.9] Therefore that third proportional will be equal to the arc of the quadrant BD; and if it be doubled, a line equal to the semicircumference of the same circle will result; if it be quadrupled, a line equal to the whole circumference. But if a line equal to the arc BK, which is less than a quadrant, is to be found: let it be arranged that, as DA is to the perpendicular LF dropped from L to AB, so that third proportional is to another line; and the fourth line found will be equal to the arc BK. For since, by Theorem 1, as DA is to the perpendicular LF, so is the arc DB to the arc BK, [Margin: m — *Elements* V.11] that third proportional will also be to the fourth line found as the arc DB is to the arc BK. But that third proportional is equal to the arc of the quadrant DB. [Margin: n — *Elements* V.14] Therefore the fourth line found will also be equal to the arc BK. But if a line equal to an arc greater than a quadrant is to be found, one must first find a line equal to a quadrant, or a semicircle, or three quadrants, according as the given arc includes one, or two, or three quadrants; then another line equal to the remaining arc, which is less than a quadrant. For these two lines joined together will be equal to the whole proposed arc.

COROLLARIVM II.

It also follows from these things that, if the base AE of the Quadratrix is set as the radius of some circle, its side AD is equal to the quadrant of that same circle, and the line double the side is equal to the circumference of that circle, and the line quadruple [the side is equal] to the whole circumference.

For since, as we said above from Pappus, the radii are proportional to the circumferences of circles, and hence also to their quadrants, it will be: as DA is to AE — that is, as that third proportional is to DA — so is the quadrant BD to the quadrant of the radius AE. But that third proportional is equal to the quadrant BD, as was shown. [Margin: o — *Elements* V.14] Therefore the line DA is also equal to the quadrant of the radius AE. Therefore the line double DA will be equal to the semicircumference of the circle whose radius is AE, and the quadruple to the whole circumference.

By the same reasoning, if two lines have the same ratio as DA and AE, and the lesser is set as the radius of some circle, the greater will be shown equal to the quadrant of that circle, and so on. For let it be, as DA is to AE, so some line B to a line C. Then, by permutation, as DA is to B, so AE is to C. But as AE is to C, so is the quadrant of the radius AE to the quadrant of the radius C, as was said above from Pappus. Therefore it will also be: as DA is to B, so the quadrant of the radius B to the quadrant of the radius C. Since, then, DA is equal, as was shown, to the quadrant of the radius AE, [Margin: p — *Elements* V.14] B will also be equal to the quadrant of the radius C. Which was proposed.

- B —————
- C —————

But if one wishes to explore by numbers what ratio, more or less, the circumference of a circle has to its diameter from this excellent discovery — or (what is the same) the semicircumference to the radius, [Margin: q — *Elements* V.15] since, as circumference is to diameter, so is semicircumference to radius — we shall do it in this way. Let us conceive the quadrant DB, in the figure in which we described the Quadratrix, to be divided into 90 degrees, and each degree into 60 minutes, so that the whole arc DB comprehends 5400 equal parts. If, then, we conceive the side DA to be divided into just as many equal parts, the parallel drawn from the last part up to the Quadratrix will be almost equal to the base AE, on account of the tiny distance between that parallel and the base AE — since in that figure the parallel GH also, cutting off AG, the sixteenth part, which is $1/16$, much greater than $1/5400$, is scarcely exceeded by the base AE: so that without notable error we may take that parallel for the base. And since that last part of the side DA is the sine of an arc of 1 minute, and that parallel is the sine of the complement, namely of an arc of 89 degrees 59 minutes — as is evident, if AG be set as the last part, and the arc BK as the last minute, and the straight line AH be drawn. For GH will be the sine of the angle GAH, 89 degrees 59 minutes, and hence AG the sine of the angle AHG, 1 minute, the whole sine being set as AH, as we showed in the treatment of Sines. If, then, the whole sine AH be set as 10000000 (for thus the desired ratio will be found more exactly than if the whole sine be set as only 100000), since in this case the sine of 89 degrees 59 minutes...

Diagram. The Quadratrix figure prepared for the numerical computation: the square with corners D (top left), C (top right), B (bottom right), A (bottom left). The side DA is divided into many equal parts, from each of which a dashed parallel runs across toward the quadratrix; dashed radial lines also fan from A to the quadrant arc, so the figure is filled with a fine grid of dashed lines. Near the base,

the last narrow strip is marked by the clustered points. This is a dense figure at the resolution floor; several of the tightly-packed lower labels are uncertain.

- D (top-left corner)
- C (top-right corner)
- G (upper on side DA): endpoint of a parallel GH near the base
- K (on the quadratrix / arc)
- I (on the right side, near B): [?]
- H (interior, low center): on the quadratrix
- F, G, A, M (clustered at the lower left, top to bottom): [?]
- E, B (on the right, near the base)
- N (lower right corner region): [?]
- P (on the lowest parallel, center): [?]

(Continuing Proposition IV, Corollary II — the numerical computation of the ratio of circumference to diameter.)

59), so that it does not differ from the whole sine, AG will be 2909 and GH 9999999. But the whole side DA, in those same parts, will be 15708600, as is established from what we said, namely that AG is 2909. The double of the side DA, therefore, will be 31417200. And since, by Corollary 2 of Proposition IV of this book, the double of the side DA is equal to the semicircumference [of the circle] whose semidiameter is AE, the ratio of that semicircumference to the semidiameter AE will be nearly the same as that of the number 31417200 to 9999999 — a ratio denominated by 3 and $\frac{1417203}{9999999}$, that is, in lowest terms, by 3 and $\frac{157467}{1111111}$. This ratio is smaller than the triple-and-a-seventh ratio [tripla sesquiseptima, $3\frac{1}{7}$], but larger than the triple-with-ten-seventy-first-parts ratio [tripla superdecupartiens septuagesimas primas, $3\frac{10}{71}$]; and the true ratio of the circumference to the diameter lies between these two, as was demonstrated by Archimedes.

Therefore, in order that a straight line equal to the circumference of the circle may be found, it is enough to find the point E, even if the whole Quadratrix line has not been drawn. But in order that an arc, or an angle, may be cut in a given ratio, we do not need the point E, as is plain.

V.

Given a circle, to construct a square equal to it.

Since Archimedes demonstrated that any circle whatever is equal to a right triangle one of whose sides about the right angle is equal to the semidiameter of the circle, while the other is equal to the circle's circumference — and since from this, in Proposition 4 of the *Isoperimetric Figures* in our commentary on the *Sphere*, we showed that the same circle is equal to the rectangle contained by its semidiameter and its semicircumference — it follows that if, by the Corollary of the preceding proposition, a straight line equal to the semicircumference of the given circle is found, and on that line together with the semidiameter [Margin: a — 14. secun. (Elements II.14)] a square is constructed equal [to the rectangle], this same square will be equal to the given circle.

Now a straight line equal to the semicircumference, or to the quadrant, or to the whole circumference, will be found [Margin: b — 12. sexti (Elements VI.12)] if it is made so that as the base of the drawn Quadratrix is to its side, so is the semidiameter of the given circle to a fourth line. For the fourth line so found will be equal to the quadrant of the circle, as we said in Corollary 2 of the preceding proposition; and doubled it will yield a line equal to the semicircumference, while quadrupled it will exhibit a line equal to the whole circumference.

But so that any circle may be squared more expeditiously, two figures most suited to squaring circles are to be constructed in this way. Let a right angle DAE be set up, and let AD be equal to the semidiameter of the Quadrant from which the Quadratrix was drawn, and AE equal to the base of that same Quadratrix; and from center A let a new Quadratrix DE be described, whose side is AD and whose base is AE. When the line DE has been drawn, one instrument most suited to squaring circles will have been constructed. For if the semidiameter of the circle to be squared is equal to the line AE, then the line AD will be equal to the circumference of the Quadrant of that same circle, as is clear from Corollary 2 of the preceding proposition. But if the semidiameter is smaller than AE, we shall cut off AB equal to it, and draw BC parallel to DE. If, finally, the semidiameter is larger than AE, we shall cut off AF equal to it on AE produced, and through F draw FG parallel to DE. For, by Corollary 2 of the preceding proposition, the line AC will be equal to the circumference of the Quadrant whose semidiameter is AB; while the line AG will be equal to the circumference of the Quadrant whose semidiameter is AF [Margin: c — 2. vel 4. sexti (Elements VI.2 or VI.4)], because as AE is to AD, so is both AB to AC and AF to AG.

Next, when a straight line HI of any length whatever has been drawn, let a perpendicular KL of any magnitude be raised upon it; and a second instrument, fitted for squaring circles, will have been prepared.

Diagram. The first instrument: a right triangle with its right angle at A (lower left). From A a vertical leg rises and a horizontal base runs to the right. On the vertical leg, read from the bottom: A, I [?], K [?], C, D, G (G at the top). On the base, from left to right: A, H, L, B, E, F. The line DE is the new Quadratrix, running from D on the vertical leg to E on the base; BC is drawn from B on the base up to C, parallel to DE; FG is drawn from F on the base up to G, parallel to DE. A construction circle (the circle to be squared) is drawn about the interior. Several of the small vertex letters sit at the resolution floor.

- A (lower-left, right-angle vertex): apex of the triangle
- G (top of vertical leg): meets parallel FG
- D (vertical leg): upper terminus of the Quadratrix DE
- C (vertical leg): meets parallel BC
- K [?], I [?] (lower vertical leg): auxiliary points
- H, L, B, E, F (base, left→right): division points; E is the base-terminus of the Quadratrix

Diagram. The second instrument, with the semicircle used in the demonstration. A long horizontal base line carries, from left to right, the points H, S, M, N, K, O [?], R, I. From K a perpendicular KL rises to the point L. A large semicircle, described from center N through H and I, cuts the perpendicular KL at L. Straight lines run from L down to points on the base. Above and to the left is a separate short horizontal segment labelled P (a given line). Point Q lies on one of the lines descending from L. The peripheral labels are small and partly at the resolution floor.

- H, S, M, N (base, left half)
- K, O [?], R, I (base, right half); N is the midpoint of HI
- L (apex, on the perpendicular and on the semicircle)
- Q (on a line from L)
- P (separate horizontal segment, upper left)

Diagram. The result of the quadrature: a square with an inscribed circle touching its four sides, the center marked with radii drawn to the circumference. This illustrates the square constructed equal to the given circle. No vertex letters are clearly legible on the square itself at this resolution.

Through these two instruments we shall square any circle whatever without difficulty, in this manner. Let there be a circle to be squared, whose semidiameter is equal, in the first instrument, to the line AB; and through B let BC be drawn

parallel to DE. But in the second instrument let two lines KM, MH be taken equal to AC, and the line KI equal to the semidiameter AB. Then, the whole line HI having been bisected at N, let a semicircle be described from N with radius NH (or NI), cutting the perpendicular KL at L. I say that the square on KL is equal to the given circle — whose semidiameter is AB in the first instrument, or KI in the second. For since KL is the mean proportional between KH and KI, by the scholium to Proposition 13 of this book, the square on KL will be equal to the rectangle under KH, KI [Margin: d — 17. septimi (?) (likely Elements VI.17, the mean-proportional theorem)]. And since this rectangle is equal to the given circle — as we said at the beginning of this proposition, KH being equal to the semicircumference and KI to the semidiameter — the same square on KL will also be equal to the given circle whose semidiameter is AB (or KI). If, therefore, the square on the line KL is described, and from its center, with radius AB (in the first instrument) or KI (in the second), a circle is drawn, we shall have a square equal to the circle, as appears in the figure set alongside.

Moreover, the division of the line HI into two equal parts, in the second instrument, will be easily made thus. Let the semidiameter KI be bisected at O — for since it is smaller than HI, it will easily be bisected — and let a line KO be taken equal to

MN. For N will be the midpoint of the line HI. For since MN, OI are equal, the common NO being added, NI will be equal to MO. But MO is equal to HN (for since HM, MK are equal, the equal parts MN, KO being added, the wholes HN, MO become equal). Therefore NI too will be equal to HN.

VI.

Given a square, to describe a circle equal to it.

Let a square be given whose side is P. From the perpendicular KL of the second instrument of the preceding proposition, cut off KQ equal to P. Then, for any circle proposed whose semidiameter is KI, let a square equal to it be found by the preceding proposition, whose side is KL. Next, when the line LI has been drawn, let QR be drawn parallel to it. I say that the circle whose semidiameter is KR is equal to the square whose side is KQ (that is, P). For, by the preceding proposition, a line KH has been found equal to the semicircumference of the circle whose semidiameter is KI; and when the line LH has been drawn, let QS be drawn parallel to it. Since therefore, because of the similarity of the triangles, as HK is to KL, so is SK to KQ; and as KL is to KI, so is KQ to KR — it will follow, *ex aequo*, that as HK is to KI, so is SK to KR. Since then HK is equal to the

semidiameter KI [recte: HK is equal to the semicircumference and KI to the semidiameter], it follows also, by Corollary 2 of Proposition 4, that SK is equal to the semicircumference of the circle whose semidiameter is KR. And since KQ, by the Corollary to Proposition 8 of this book, is the mean proportional between SK and KR — because the angle RQS is right [Margin: a — 29. primi (Elements I.29)], seeing that its parts RQK, SQK are equal to the parts ILK, HLK of the right angle HLI (for [Margin: b — 31. tertij (Elements III.31)] the angle HLI is right, being in a semicircle, as is evident from the construction of the preceding proposition, by which KL is found to be the mean proportional between HK and KI) — it follows [Margin: c — 17. sexti (Elements VI.17)] that the square on KQ is equal to the rectangle under SK, KR; that is, to the circle whose semidiameter is KR. That is, the circle of semidiameter KR is equal to the square on the side KQ (that is, P). Which was to be shown.

COROLLARIVM.

From what has been demonstrated we shall construct a circle equal to any rectilinear figure whatever; and conversely, we shall construct, equal to any circle whatever, a rectilinear figure similar to any other given rectilinear figure. For if to a given rectilinear figure [Margin: d — 14. secun. (Elements II.14)] we describe an equal square, and to this square construct an equal circle, then by Proposition 6 this same circle will be equal to the given rectilinear figure.

Again, if by Proposition 5 we construct a square equal to a given circle, and to this square [Margin: e — 25. sexti (Elements VI.25)] construct a rectilinear figure equal [to it] and similar to another given rectilinear figure, then this same rectilinear figure so constructed will be equal to the given circle. Which was to be shown.

VII.

Given a straight line, to find a circumference of a circle equal to it.

By what method a straight line may be found equal to the circumference of a given circle, we taught in Proposition 5; now, so that conversely a circumference of a circle equal to a given straight line may be found, we must proceed thus. Let a straight line A be given, to which a circumference is to be found equal. Any circle BC having been described about center D, let a line E equal to it [that is, to A] be found, which will easily be done thus. In the first instrument of Proposition 5, let AH be taken equal to the semidiameter BD of the described circle, and through H let HI be drawn parallel to DE. For AI, quadrupled, will give a line E equal to the circumference of the circle BC, as we said in Proposition 5. Then, to

the three lines E, A, BD, let a fourth proportional FG be found, and from G, with radius GF, let a circle FH be described. I say that its circumference is equal to the given line A. For since, as E is to A, so is BD to FG — that is [Margin: a — 15. quint. (Elements V.15)], so is the whole diameter of circle BC to the whole diameter of circle FH; and since [Margin: b — 11. quint. (Elements V.11)] as diameter is to diameter, so is the circumference BC to the circumference FH (as Pappus demonstrated) — it follows also that as E is to A, so is the circumference BC to the circumference FH. Since then E has been made equal to the circumference BC, it follows [Margin: c — 14. quint. (Elements V.14)] that the line A too is equal to the circumference FH; that is, the circumference of the circle FH has been found equal to the given line A. Which was to be shown.

Otherwise, and more easily. Take AK equal to the fourth part of the given line A, in the first instrument of Proposition 5, and through K draw KL parallel to DE. For the circumference of the circle whose semidiameter is AL will be equal to the given line A; because the quadrant of that circumference is equal to the line AK, the fourth part of the given line A, as we showed in Proposition 5.

VIII.

Given two unequal circles, and given an arc in one of them, to cut off from the other an arc equal to it. But the arc given in the larger circle must not be greater than the circumference of the smaller circle.

Let there be two unequal circles AB, CD, whose centers are E, F and semidiameters AE, CF, and let AB be the larger and CD the smaller. First let an arc CD be given in the smaller circle, to which an equal arc is to be cut off from the larger. Since the circle AB is larger than the circle CD, the semidiameter AE will also be larger than the semidiameter CF. Let AG then be cut off equal to CF, and let the arc CD be cut at H, by Proposition 2, so that the ratio of arc CH to arc HD is the same as that of the line AG to the line GE; and let there be cut off from AB an arc similar to CH — which will be done easily if, when the line FH has been drawn, the angle AEB is made equal to the angle CFH. I say that the arc AB is equal to the given arc CD. For since, as AG is to GE, so is arc CH to arc HD; and, by inversion, as EG is to AG, so is arc DH to arc CH — it follows, by composition, that as AE is to AG (that is, to CF, which is equal to AG), so is arc CD to arc CH. But as AE, the semidiameter, is to the semidiameter CF [Margin: a — 15. quint. (Elements V.15)], that is, as the whole diameter is to the whole diameter, so — from what Pappus demonstrated — is the circumference of circle AB to the circumference of circle CD, that is, so is arc AB to the similar arc CH. Therefore [Margin: b — 11. quint. (Elements V.11)] it will also follow that as arc CD is to arc CH, so is arc AB to

that same arc CH; and consequently the arcs CD, AB [Margin: c — 9. quinti (Elements V.9)] will be equal to one another. Which was to be shown.

Diagram. The figure for Proposition VII. At the top are two horizontal segments: the upper one, A, divided by tick-marks into four equal parts (the given line); and below it the shorter segment E. Beneath them are two circles: on the left a smaller circle with horizontal diameter B–D (B at the left, D the center) and C marked at the top — this is the circle BC; on the right a larger circle with diameter F–G (F at the left, G the center) and H at the upper right — this is the circle FH.

- A (upper segment): the given line, divided into four parts
- E (lower segment): line found equal to the circumference of circle BC
- B, C, D (left circle): B and C on the circle, D the center
- F, G, H (right circle): F and H on the circle, G the center

Diagram. The figure for Proposition VIII: two unequal circles. On the left, the larger circle AB with center E: A at the left end of a horizontal diameter, G near the center, and B, K, L at the bottom marking the arc AB and its construction. On the right, the smaller circle CD with center F: C at the left, I near the center, and H, D at the bottom marking the arc CD.

- A, G, E (left circle): A on the circle, E the center, G on the diameter AE (with $AG = CF$)
- L, B, K (left circle, bottom): division/construction points of arc AB
- C, F, I (right circle): C on the circle, F the center, I on the diameter
- H, D (right circle, bottom): H the point of section of arc CD, D on the circle

Next let there be given, in the larger circle, an arc AB not greater than the circumference of the smaller circle CD, from which an arc equal to the arc AB is to be cut off. Since the circle AB is larger than the circle CD, the semidiameter AE will also be larger than the semidiameter CF. Let CF then be produced to I, so that CI is equal to AE; let the arc AB be cut at L, by Proposition 2, so that the ratio of AB to BL is the same as that of CF to FI; and to the arc BL let there be taken an equal arc BK, and from the whole arc AK let a similar arc be cut off, so that the angle CFD is made equal to the angle AEK. I say that the arc CD is equal to the given arc AB. For since, as CF is to FI, so is arc AB to arc BL (that is, to arc BK, which is equal to BL), it will follow, by composition, that as CI is to FI, so is arc AK to arc BK; and, by conversion of ratio, that as CI is to CF — that is, as AE is to CF — so is arc AK to [arc AB]. But as AE is to the semidiameter CF [Margin: d — 15. quin. (Elements V.15)], that is, as the whole diameter is to the whole diameter, so — from what Pappus demonstrated — is the circumference of circle AB to the circumference of

circle CD, that is, so is arc AB to the arc CD similar to it. Therefore [Margin: e — 11. quinti (Elements V.11)] it will also follow that as arc AK is to arc CD, so is that same arc AK to arc AB; and consequently the arcs AB, CD [Margin: f — 9. quinti (Elements V.9)] will be equal to one another. Which was to be shown.

More briefly. Let a straight line equal to the arc CD be found, by Corollary 1 of Proposition 4 on the Quadratrix; and to this line let an arc AB be found equal, as will be shown in the following Corollary 1. In the same way, let a straight line equal to the arc AB be found, so that to this line an arc CD may be found equal: and what is required will be done.

COROLLARIVM I.

From what has been demonstrated it is manifest that from any circle whatever whose circumference is not smaller than a given straight line, a circumference can be cut off equal to any given straight line — just as it was shown above, in Corollary 1 of Proposition 4, that a straight line equal to any given circumference can be found — in this way. By the means which we showed a little before in Corollary 1 of Proposition 4, let a straight line be found equal to the quadrant of the given circle. And if indeed this line so found is equal to the given straight line, then the circumference of the quadrant will be equal to the given straight line.

But if that line found equal to the quadrant of the circle is larger than the given straight line, let the circumference of the quadrant be cut into two parts, by Proposition 2, so that the quadrant has the same ratio to one part as the line found has to the given straight line. For that part of the quadrant will be equal to the given straight line. For since, as the line found is to the given line, so is the quadrant to that arc cut off; and since the line found is equal to the quadrant [Margin: g — 14. quin. (Elements V.14)], it follows also that the given straight line is equal to the arc cut off.

But if, finally, that line found equal to the quadrant is smaller than the given straight line, let its double be taken — which of course will be equal to the circumference of the semicircle. For if this is equal to the given straight line, the circumference of the semicircle will be equal to the same given straight line.

But if that double line is larger than the given straight line, let the circumference of the semicircle be cut into two arcs, so that the semicircumference has the same ratio to one of them as that double line has to the given straight line. This indeed will easily be done if from that double line one equal to the given line is cut off, and the semicircumference is cut, by Proposition 2, in the same way as that double line has been cut. For it will follow, by composition, that as the whole

double line is to the part cut off — that is, to the given line — so is the whole semicircumference to the arc cut off. For that arc will be equal to the given line. For since, as the double line is to the given line, so is the semicircumference to that arc; and since that double line is equal to the semicircumference [Margin: h — 14. quin. (Elements V.14)], it follows also that the given line is equal to that arc.

But if, finally, that double line is smaller than the given straight line, let the earlier line found — which of course is equal to the quadrant of the circle — be added to it, so that the whole composite line is equal to the circumference of three quadrants, and triple the earlier line found. For if this triple line is equal to the given straight line, the arc of three quadrants will be equal to the same given straight line.

But if that triple line is larger than the given straight line, let the circumference of three quadrants be cut into two arcs, by Proposition 2, so that it has the same ratio to one of them as that triple line has to the given line — which will easily be done if from that triple line a line equal to the given line is cut off, and the circumference of three quadrants is cut, by Proposition 2, in the same way as that triple line has been cut. For, by composition, it will follow that as the whole triple line is to the part cut off — that is, to the given line — so is the whole circumference of three quadrants to the arc cut off. For that arc will be equal to the given straight line. For since, as that triple line is to the given line, so is the circumference of three quadrants to the arc cut off; and since that triple line is equal to the circumference of three quadrants [Margin: i — 14. quint. (Elements V.14)], it follows also that the given straight line is equal to that arc cut off.

Finally, if that triple line is smaller than the given straight line, let there be added to it again the earlier line found equal to the quadrant, so that the whole composite line becomes equal to the whole circumference of the circle, and quadruple the earlier line found. For if this quadruple line is equal to the given straight line, the whole circumference of the given circle will be equal to the given straight line.

But if that quadruple line is larger than the given straight line (it cannot be smaller: otherwise the given straight line would be larger than the circumference of the given circle, which is contrary to the hypothesis), let the whole circumference be cut into two arcs, by Proposition 2, so that it has the same ratio to one of them as that quadruple line has to the given line — which will easily be done if from that quadruple line a line equal to the given line is taken away, and the whole circumference of the circle is cut in the same way as that quadruple line has been cut. For, by composition, it will follow that as the whole quadruple

line is to the part cut off — that is, to the given line — so is the whole circumference of the circle to the arc cut off. For that arc will be equal to the given line. For since, as that quadruple line is to the given straight line, so is [the whole circumference] to the arc cut off; and since that quadruple line is equal to the whole circumference [Margin: k — 14. quin. (Elements V.14)], it follows also that the given straight line is equal to the arc cut off.

Otherwise, and more briefly. When, by Corollary 1 of Proposition 4 on the Quadratrix (or by Proposition 5 of the same), a straight line equal to the circumference of the given circle has been found, let there be cut off from it a line equal to the given straight line, and let the whole circumference be cut, by Proposition 2, into two parts in the same way as that line found has been cut. For, by composition, it will follow that as the whole line is to the part removed from it — that is, to the given line — so is the whole circumference to the arc cut off. Since then the whole line is equal to the whole circumference [Margin: l — 14. quint. (Elements V.14)], it follows also that the given straight line is equal to the arc cut off. Which was to be shown.

COROLLARY II.

From what has been said it can also be inferred that both arcs and rectilinear angles may be found that are incommensurable with one another. For let the arc HB be given, together with the rectilinear angle HAB. I say that the arc HB can be divided into two arcs incommensurable with one another, and likewise the angle HAB into two angles incommensurable with one another.

For, having drawn the quadratrix DE, which cuts the straight line HA at F, draw through F the line FI parallel to the base AE. Then, having found two straight lines incommensurable with one another (as is taught in Book 10), divide the straight line IA at N — by the scholium to proposition 10 of this book — in such a way that IN has to NA the same ratio that the two lines found have to each other; and so IN and NA will likewise be incommensurable. Now draw the straight line NK parallel to AE, cutting the quadratrix at K, and from the centre A draw through K a straight line cutting the arc HB at L. I say that the arcs HL and LB, as well as the angles HAL and LAB, are incommensurable with one another.

For, by proposition 1, as IN is to NA, so is the arc HL to the arc LB; but IN and NA are incommensurable; therefore the arcs HL and LB will also be incommensurable. [Margin: d — VI.33.] Since then it also holds that, as the arc HL is to the arc LB, so is the angle HAL to the angle LAB, the angles HAL and LAB will

likewise be incommensurable with one another. Which was what was to be proved.

Diagram. A square with corners A (bottom-left), B (bottom-right), C (top-right), and D (top-left), with A the centre of a quarter-circle arc running from D (top-left) down to B (bottom-right). The quadratrix curve runs from D down to E on the base AB. From the centre A two radial lines are drawn to the arc, one through F to H, the other through K to L. Two horizontal lines (FI and NK) are drawn parallel to the base. The left side AD and the right side BC carry equal tick-mark divisions.

- A (bottom-left corner): centre of the arc and of the square
- B (bottom-right corner): endpoint of the arc on the base line
- C (top-right corner)
- D (top-left corner): endpoint of the arc; start of the quadratrix
- H (on the arc, upper): endpoint of the radius through F
- F (on radius AH): where the quadratrix cuts the line HA; left end of the horizontal FI
- I (on the left side AD): right — level with F; endpoint of the horizontal FI
- L (on the arc, lower right): where the radius through K cuts the arc HB
- K (on the quadratrix): where the horizontal NK cuts the quadratrix
- O (near the centre): interior intersection point
- N (on the left side AD, lower): left end of the horizontal NK; the division point of IA
- G (on the base AB)
- M (on the base AB)
- E (on the base AB): foot of the quadratrix

FINIS ELEMENTI SEXTI

[The End of the Sixth Element.]

EUCLID'S ELEMENTS, BOOK SEVEN

[EVCLIDIS ELEMENTVM SEPTIMVM.]

DEFINITIONS

I.

Unity is that according to which each of the things that exist is said to be one.

Up to this point Euclid has dealt with the earlier part of geometry — that, namely, which concerns plane figures; there remained the other part, which concerns solids. But it was first necessary for him to treat of commensurable and incommensurable lines, since for demonstrating the properties of very many bodies — and most of all those called regular — and for explaining them as one should, a knowledge of these lines is required. So much so, indeed, that without them the treatment of solids would be incomplete and not fully worked out in its numbers. To this is added that, without these same lines, very many sides both of plane figures and of solids can be neither expressed nor understood, if the theory of geometry is put to work and use. For not seldom the sides of figures are those lines which by the Greeks are called ἄλογοι [Greek: ἄλογοι (alogoi, "irrational," "inexpressible")] and by the Latins "irrational"; or, if they are not irrational, they are at least incommensurable with one another in length, and so do not fall under the measure of numbers. And because the explanation and understanding of these same lines is bound up and joined with numbers, so that without numbers they cannot be known at all, it was necessary — in order that the doctrine might keep its proper order and reasoning — that the account of numbers be set before those lines. For this reason, in this seventh book and in the two that follow it, he is occupied with the properties and affections of numbers, so far as they serve the geometrical subject, so that thereafter, in the tenth book, the demonstrations concerning commensurable and incommensurable lines may be carried through more easily and more fully.

Beginning therefore, in his usual manner, from first principles, he defines at the outset "unity," and teaches that it is that according to which each of the things that exist is said to be one. For it is in respect of unity that we are accustomed to speak of one stone, one animal, one body, and so on. Moreover, unity admits of no division among numbers, just as the point admits of none among magnitudes, as we taught in the first book.

II.

Number, moreover, is a multitude composed of units.

Since number is a certain multitude composed of units, it is clear that any number whatever has as many parts as there are units constituting it — so that the unit is a part of any number, named after the number itself of which it is a part. Thus the number 8, composed of eight units, is divided into just so many parts, namely into 8 units, each of which is called an eighth part of the number eight. In the same way the number 100, composed of a hundred units, is distributed into just as many parts, each of which is a hundredth part of it, and so on.

From this it follows that all numbers, however many there be, are commensurable with one another, since one and the same measure — namely the unit, as has been said — measures them. This can in no way hold for all magnitudes, since very many of them have no common measure, but are utterly incommensurable, as will be shown most clearly in Book 10.

III.

A part is a number of a number — the lesser of the greater — when the lesser measures the greater.

This definition is not unlike the one by which Euclid, in Book 5, set out the "part" of a continuous quantity. For just as there, so here too, he defines only an aliquot part, since only this is properly said to measure the whole, as we explained more fully in that place. And so the number 6 will be called a part of all these numbers: 12, 18, 24, 30, 60, 630, and so on, because it measures each of them. Likewise the parts of the number 576 will be all these numbers: 3, 4, 6, 8, since each of these measures it, as is evident.

[Signature]

Now every part takes its name from that number by which it measures the number of which it is a part: thus 6, a part of the number 42, draws its name from 7, since 6 measures 42 by 7. And so 6 will be a seventh part of the number 42, and it is the same with the rest.

IV.

"Parts," however, when it does not measure.

Euclid intends that a number less than a greater number, which it does not measure, be called not a "part" but "parts": such is the number 5 when compared with the number 18. For although — since it does not measure the greater except through its own units — it ought not to be called a part of it, nevertheless it can

fittingly and appropriately be called "parts," because it contains five units, each of which is an eighteenth part of the number 18. Hence we shall call the number 5 "five eighteenth-parts" of the number 18. From this it plainly follows that Euclid understood by the name "part" only an aliquot part, and not also an aliquant part, as some would have it; otherwise this fourth definition, which comprehends the aliquant part, would be superfluous.

Furthermore, "parts," whatever they may be, take their name from those two numbers by which the common measure of the two numbers measures each of them — namely both the one which is called "parts" and the one of which it is called the parts. So that if the common measure of two numbers measures the lesser by 3 and the greater by 5, the lesser is said to be "three fifths" of the greater. Such parts are: 6 of the number 10. For their common measure, 2, measures 6 by 3 and 10 by 5. By the same reasoning we shall call the same number 6 "six tenths" of the same number 10, since the unit, their common measure, measures the one by 6 and the other by 10. Hold the same judgement for the rest.

But if you should ask why Euclid in this place defines not only the lesser number that is a part of the greater, but also the one that is "parts," whereas in the fifth book, dealing with magnitudes, he did not do the same — for he did not there call "parts" that lesser magnitude which does not measure the greater, but only the one which measures the greater by a part — we reply that the reason is this: every lesser number is either a part or parts of any greater number, as will be shown in proposition 4 of this book — a part, when it measures it; parts, when it does not measure it. But with magnitudes the matter stands far otherwise. For, given two unequal magnitudes, the lesser is not necessarily either a part or parts of the greater, since they are very often incommensurable, as the tenth book will openly demonstrate, and so the lesser may in no way contain several parts of the greater. For only among commensurable magnitudes does the lesser comprehend several parts of the greater, if it does not measure it. Rightly, therefore, did Euclid in the fifth book explain only the "part" among magnitudes, but here, among numbers, both "part" and "parts."

V.

A multiple, on the other hand, is the greater of the lesser, when the lesser measures the greater.

Just as only that lesser number is called a part of the greater which measures the greater, so too only that greater number is called a multiple of the lesser which

the lesser measures — so much so that the greater number, of which the lesser is a part, is in turn a multiple of the lesser. Thus the number 6 is a part of the number 30, and the latter is a multiple of the former, and so on. But if the lesser does not measure the greater, the greater will in no way be a multiple of the lesser. For if the greater were a multiple of the lesser, the lesser would measure the greater, by this definition. And conversely, if the greater is not a multiple of the lesser, the lesser will not measure the greater; for if the lesser did measure the greater, then by this definition the greater would be a multiple of the lesser.

VI.

An even number is one that is divided into two [equal parts].

Thus all these numbers — 4, 10, 40, 100, 1000 — are called even, because they are divided into two, that is, into two equal parts, since their halves are 2, 5, 20, 50, 500.

VII.

An odd number, on the other hand, is one that is not divided into two [equal parts]. Or, one that differs from an even number by a unit.

All these numbers — 5, 11, 15, 37, 101, 1001 — are called odd, because they cannot be divided into two equal parts. Or certainly because they differ by a unit from these even numbers — 4, 10, 14, 36, 100, 1000 — or also from these — 6, 12, 16, 38, 102, 1002. From this passage it can be plainly gathered that the unit in numbers is utterly indivisible. For if it were divided, every odd number would have a half, and so could be divided into two equal parts. For the half of this odd number, 11, would be five units and a half — the contrary of which Euclid taught by this definition.

VIII.

An even-times-even number is one which an even number measures by an even number.

Since an even number is one that is divided into two equal parts, it comes about that some even number, at least two, measures any even number. That even number, then, which an even number measures by an even number, is called "even-times-even." Such is this even number, 32; for the even number 8 measures it by the even number 4. In the same way the even number 24 will be called even-times-even, since the even number 4 measures it by the even number 6, and so on.

IX.

An even-times-odd number, on the other hand, is one which an even number measures by an odd number.

But if an even number measures an even number by an odd number, it will be called "even-times-odd." Such is the even number 30; for the even number 2 measures it by the odd number 15. In the same way the even number 6 measures the same [30] by the odd number 5, and so on.

Furthermore, if the two immediately preceding definitions are rightly weighed, it will be evident that it can happen that one and the same even number is both even-times-even and even-times-odd. For the even number 24, since the even number 6 measures it by the even number 4, will be even-times-even. Again, because the even number 8 measures the same [24] by the odd number 3, it will also be called even-times-odd. Hence some interpreters, thinking this to be absurd, in order to exclude even numbers of this kind — which appear to be both even-times-even and even-times-odd — added to each definition the qualifying word "only," so that an even-times-even number, according to them, is one which an even number

measures it by an even number only; whereas an even-times-odd number is one that an even number measures by an odd number only. For it turns out that the given even number 24 is neither even-times-even — since it is measured not only by 6 taken an even number of times (four), but also by 8 taken an odd number of times (three) — nor even-times-odd, since it is measured not only, as was said, by 8 through the odd number 3, but also by 6 through the even number 4. Rather it can fittingly be called both even-times-even and even-times-odd, for it shares in a way the nature of both, as is clear. And so three genera of even number, most distinct among themselves, are established: even-times-even; even-times-odd; and the even-times-even-and-odd, which some call "even-times-even and odd-wise" [*pariter par & impariter*].

Yet although all this is true, and correctly explained on the view of the Pythagoreans, Nicomachus, Boethius [Boethius], and others, it is nonetheless wholly foreign to Euclid's [Euclid's] approach — as is clear both from the definitions handed down, in which that word "only" [*tantum*] which they add is not found, and from Propositions 32, 33, and 34 of Book 9 (*Elements* IX.32–34). There Euclid plainly calls every even number that some even number measures by an even number "even-times-even," but the one that some even number measures by an odd number "even-times-odd"; and finally the one that an even

number measures both by an even and by an odd number he calls both even-times-even and even-times-odd. And he demonstrates that all numbers that are successive doubles of two — such as 2, 4, 8, 16, 32, 64, 128, etc. — are even-times-even only; that is, that even numbers measure them by even numbers only. But numbers that have odd halves are even-times-odd only — that is, even numbers measure them by odd numbers only — of which sort are 6, 10, 14, 18, 22, etc. And finally, numbers that are neither doubles of two nor have odd halves are both even-times-even and even-times-odd, such as 12, 20, 24, 28, 36, etc. And so Euclid holds, in the demonstrations of those propositions, that these last numbers, and others like them, are truly, according to the definitions handed down, even-times-even; and again are rightly called even-times-odd — although they are neither even-times-even only nor even-times-odd only. But these matters will be understood more clearly from Book 9.

X.

An odd-times-odd number [*impariter impar*], by contrast, is one which an odd number measures by an odd number.

As this odd number 15 is called odd-times-odd, since the odd number 3 measures it by 5, an odd number. In the same way these odd numbers — 9, 21, 25, 27, 33, 35, 39, 135, 2025, and infinitely many others — are named odd-times-odd.

XI.

A prime [first] number [*primus*] is one which unity alone measures.

If no number, but unity alone, measures some number — so that it can be called neither even-times-even, nor even-times-odd, nor odd-times-odd — it will be called a prime number; such are all these: 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, etc. For unity alone measures them.

XII.

Numbers prime to one another [*primi inter se*] are those which unity alone, as a common measure, measures.

Just as the number that unity alone measures is called prime, so too two, three, four, or even more numbers — which no number besides unity measures as a common measure, although each of them individually has numbers that measure it besides unity — are called prime to one another. Thus 15 and 8 are numbers prime to one another, because unity alone, as a common measure, measures them: for although the numbers 3 and 5 measure the former, and 2 and 4 the

latter, yet none of these measures both, but unity alone is the common measure of both. So too these numbers 7, 10, 15 are said to be prime to one another, because besides unity they have no number as a common measure — even though the last two [10 and 15] have this number 5 as a common measure. Finally, unity and any number can be said, though improperly, to be numbers prime to one another, because unity alone measures both unity and any number, as a common measure.

XIII.

A composite number [*compositus*] is one which some number measures.

A number which, besides unity, some other number measures, the geometers call composite — such as this 15. For each of these numbers, 3 and 5, measures it. And it is clear that all even numbers except 2 are composite, since 2 measures them all. From which it follows that all prime numbers except 2 are odd, since among the even numbers 2 alone is prime, as we said.

XIII.

Numbers composite to one another [*compositi inter se*] are those which some number, as a common measure, measures.

Two or more numbers which, besides unity, some other number measures as a common measure, are said to be composite to one another — even though not every one of them is itself a composite number; just as the number that, besides unity, some number measures is called composite. Thus these numbers 15 and 24 are composite to one another, because this number 3 measures them as a common measure. In the same way these numbers 7, 21, 35 will be composite to one another. For the first of them measures both itself and the other two — although, taken by itself, it is called prime.

XV.

A number is said to multiply a number when the one that is multiplied is composed as many times as there are units in the multiplier itself, and some number is produced.

Thus 6 is said to multiply 8 when 8 is composed six times — namely, as many times as there are units in the multiplier 6 — and the number 48 is produced. And likewise, conversely, 8 is said to multiply 6 if we take 6 eight times — that is, as many times as there are units contained in the multiplier 8 — and produce the same number 48. By the same reasoning, finally, these numbers 100, 1000, 20, etc.

are said to multiply 456 when it is taken a hundred times, a thousand times, or twenty times, etc., and these numbers are generated: 45600, 456000, 9120, etc. And so a number is said to be produced, generated, or procreated from two numbers when, one multiplying the other, a product results. Thus 63 is said to be generated from these numbers 7 and 9, because it is procreated from the multiplication of 7 into 9, or the reverse. And so with the rest.

It follows from this that the number produced by the multiplication has the same ratio to either of the multipliers as the other multiplier has to unity. For since, by Euclid's definition, either multiplier must be composed as many times, to make the product, as there are units in the other multiplier, the product will contain either multiplier as many times as the other multiplier contains unity; and therefore the product will have the same ratio to either multiplier as the other multiplier has to unity. And so multiplication — that is, the drawing [*ductus*] of one number into another — can also be described thus:

The multiplication of a number into a number is the finding of a number that has the same ratio to either multiplier as the other multiplier has to unity.

Thus you see that from the multiplication, or drawing, of 6 into 8, the number 48 is generated, which stands to 6 as 8 to 1, or to 8 as 6 to 1.

To this definition must be added another, teaching what it is for a number to divide a number — since it is altogether necessary for the things we are going to demonstrate in what follows.

A number is said to divide a number when a number is taken which, by its units, indicates how many times the dividing number is contained in the divided one.

Thus 6 is said to divide 48 when the number 8 is taken, which by its eight units indicates that the dividing number 6 is contained eight times in the divided number 48. And likewise, conversely, 8 is said to divide the same 48 if 6 is taken, which by its six units indicates that the dividing number 8 is contained six times in the divided number 48.

Hence it follows that the number produced by the division has the same ratio to unity as the divided number has to the divisor. For since, as we said in the definition, the produced number must indicate by its units how many times the dividing number is contained in the divided one, the product will contain unity as many times as the divided number contains the divisor; and therefore the

number generated by the division will have the same ratio to unity as the divided number has to the divisor. And so the division of one number by another can also be described thus:

The division of a number by a number is the finding of a number that has the same ratio to unity as the divided number has to the divisor.

Thus you see that from the division of 48 by 6 there is produced 8, which stands to 1 as 48 to 6; and likewise from the division of the same number 48 by 8 there is produced 6, which stands to 1 as 48 to 8.

From these it is also established that, when a number is divided by a number, the divided number is generated by the multiplication of the number found through the division into the dividing number. For let a number A be divided by B, and let the number C be produced; I say that A is generated from the drawing of the number C into the number B. For since, by the definition of multiplication, the number produced from C into B stands to B as C to unity D; and by the definition of division, A likewise stands to B as C to unity D; it is clear that the number generated from C into B is the number A, since both that generated number and A have the same ratio to B as C to D, unity.

A, 48. B, 8. C, 6. D, 1.

All this holds also for fractions, and for integers together with fractions: that is, a fraction is said to multiply a fraction — or an integer a fraction, or a fraction an integer (whether the fractions are attached to integers or not) — when the one that is multiplied is composed as many times as there are units in the multiplier itself, and some number is produced; and to divide, when a number is taken which indicates how many times the divisor is contained in the divided one. So that in multiplication there is likewise found a number having the same ratio to either multiplier as the other multiplier has to unity, while in division there is produced a number having the same ratio to unity as the divided number has to the divisor. Thus $1/2$ is said to multiply 20 when 20 is composed as many times as there are units in $1/2$, and the number 10 is produced. For since unity is in $1/2$ only by its half, 20 too must be taken by its half, which is 10. And likewise, conversely, 20 is said to multiply $1/2$ if $1/2$ is taken twenty times — namely, as many times as unity is in 20 — and the same number 10 is produced. Here you see that the produced number 10 has the same ratio to $1/2$ as the other multiplying number 20 has to 1; or that 10 is to 20 as $1/2$ to 1. So too $1/2$ and $1/3$ are said to multiply each other, when $1/2$ is taken by its third part — inasmuch as $1/3$ contains only a third part of unity — or when $1/3$ is taken by its half, because

$1/2$ too contains only a half of unity. In either way $1/6$ is produced, which is a third part of the number $1/2$, or $3/6$, and half of the number $1/3$, or $2/6$. In what manner multiplication is to be carried out with fractions we have taught in the *Arithmetic*, and will demonstrate at the end of Book 9.

Again, $1/2$ is said to divide 10 when the number 20 is taken, indicating that the dividing number $1/2$ is contained twenty times in the divided number 10 — so that the same ratio holds of the produced number 20 to 1 as of the divided number 10 to the divisor,

$1/2$. So too $1/2$ is said to divide $1/6$ when the number $1/3$ is taken, indicating that the dividing number $1/2$ is not contained wholly in the divided number $1/6$, but only a third part of it. For since the number $1/2$ is the same as $3/6$, it clearly follows that a third part of it, namely $1/6$, is contained in $1/6$. As to how division is to be carried out with fractions, we have handed it down in the *Arithmetic*, and will demonstrate at the end of Book 9, where all these things we have said about the multiplication and division of fractions will become clearer.

XVI.

But when two numbers multiplying each other make some number, the number so made will be called plane [*planus*]. And the numbers that have multiplied each other will be called its sides.

Every number produced from the mutual multiplication of two numbers is called plane, because, by its units arranged in length and breadth, it represents a rectangular parallelogram whose sides are the two multiplying numbers — which are therefore called the sides of the produced number, because they contain it, just as straight lines enclosing a right angle are said to contain a rectangular parallelogram, as we explained more fully in Book 2. Thus 24, produced from the mutual multiplication of 4 and 6, is called plane, and its sides are 4 and 6, because its units, arranged in length and breadth as the sides require, represent a rectangular parallelogram, one side of which comprises six units and the other 4. In the same way 64, generated from the mutual multiplication of 8 and 8, is called plane, and its sides are 8 and 8.

However, although there are infinitely many kinds of plane numbers among the arithmeticians — just as there are plane figures among the geometers — Euclid defines only the rectangular quadrilateral plane number, namely the one contained under two numbers from whose mutual multiplication it is generated, since in these books he discusses only this kind of number: one which in every respect is similar and equal to a geometrical square, and to a figure longer on one

side [an oblong], whether you regard the perimeter, the area, or the capacity. He says nothing about triangular, pentagonal, hexagonal, and other such numbers, because these, although they agree with a geometrical triangle, pentagon, hexagon, etc. as regards the perimeter, nevertheless, if you consider the area or capacity, differ greatly from them. This is clear to anyone who reads carefully through these books of Euclid and the *Arithmetic* of Jordanus [Jordanus Nemorarius].

Moreover, one and the same plane number can have several sides, since it can be produced from several multiplications. Thus 24 has not only the sides 4 and 6, but also 3 and 8, and moreover 2 and 12, because it is generated as much from the multiplication of 4 into 6 [as from the others]. Likewise the plane number 100 has the sides 5 and 20; 4 and 25; 2 and 50; 10 and 10 — because it is generated from all these numbers, if they are multiplied two by two.

And since two numbers multiplying each other measure every plane number — because each of them, taken as many times as there are units in the other, produces it — it clearly follows that every plane number is composite. This can also be said of a solid number, which is being defined just now. It is true that unity can sometimes be called a plane number, though improperly, because its sides are two unities, which, multiplied together, produce unity itself.

XVII.

But when three numbers multiplying each other make some number, the one procreated will be called solid [*solidus*]. And the numbers that have multiplied each other will be called its sides.

Thus, because these three numbers 2, 3, 4, multiplying one another, produce 24. For from 2 into 3 the number 6 is procreated, and from 6 into 4, 24 results; or from 2 into 4 the number 8 is generated, and from 8 into 3, 24 is effected; or, finally, from 3 into 4 the number 12 is produced, and from 12 into 2, 24 is generated — the number 24 will be called solid, and the numbers 2, 3, 4 will be called its sides, because its units, arranged in length, breadth, and depth, represent a certain solid figure, which is called a parallelepiped, as we shall explain in Book 11. Its three dimensions are all expressed by the three numbers multiplying one another: one gives the length, another the breadth, and the remaining one the height. For if the first is multiplied by the third — that is, if 2 by 4 — the number 8 results, the base of the solid number, four units long and two broad; and if this base is multiplied by 3 — that is, taken three times — the whole solid number 24 arises, having a height of three units. But if 2 is multiplied

by 3, they will have a base of 6 units, which multiplied by 4 makes the whole solid number 24, having 4 units in height. If, finally, 3 is multiplied by 4, the number 12 is produced as a base, which taken twice makes the same solid number 24, whose height contains two units. All of which is evident in the figure set out.

Diagram. A rectangular parallelepiped (an oblong box) drawn in oblique projection and ruled into a grid of unit cubes, illustrating the solid number 24 (4 long $\times$ 2 deep $\times$ 3 high). Eight vertices are lettered :

- E (top face, back-left corner)
- H (top face, back-right corner)
- A (top face, front-left corner)
- D (top face, front-right corner)
- B (bottom face, front-left corner)
- C (bottom face, front-right corner)
- F (bottom face, back-left corner)
- G (bottom face, back-right corner)

The base BCGF has length BC (four units) and breadth BF (two units); the height BA (equivalently AE) runs three units.

For if the base is BCGF, of eight units — whose length BC comprises four units, and BF, the breadth, two — two other bases, similar and equal, will be superimposed upon it, so that the whole solid number contains 24 units, and its height BA is three units. Similarly, if the base is ABFE, of six units — whose length AB contains three and breadth BF two units — three other similar and equal bases will be superimposed upon it, and the whole solid number will again become 24, having a height BC of four units. If, finally, the base is ABCD, of 12 units — whose length BC contains four and breadth AB three — another base similar and equal, EFGH, will be superimposed upon it, and the whole solid will consist of 24 units, two of which will give the height AE, or BF. This same solid number 24 has these sides 6, 2, 2, since it is produced from these multiplied together. And in the same way one must judge of other solid numbers.

Finally, the unit too will sometimes be called a solid number, though not properly so, since its sides are three units, which produce the unit itself by multiplying one another.

Here too Euclid defines only the *right-angled* solid number — whose opposite bases are parallel, and which is contained under three numbers — passing over the infinitely many other kinds treated by Jordanus [Nemorarius], for the reason

given in the preceding definition: namely, because these are exactly equal and similar to the cubes and parallelepipeds of geometry.

XXVIII. [recte: XVIII]

A **square number** is one that is equal times equal; or one that is contained under two equal numbers.

Diagram. A square array of 25 dots (five rows of five), illustrating the square number 25 arranged as a plane figure five units on each side. No labels; the array is uncaptioned.

He calls a *square* that plane number which is equal times equal — that is, one which, when its units are laid out lengthwise and breadthwise, represents a rectangular parallelogram whose length equals its breadth, so that all its sides are equal; or one produced by the mutual multiplication of two equal numbers, and so contained under them. Of this kind is the number 25, contained under the equal numbers 5 and 5 — that is, generated by their mutual multiplication. For if its units are reduced to a plane figure, it represents a perfect geometrical square with five units on each side, and so it is equal times equal.

Either one of the equal numbers under which a square number is contained, or from whose multiplication it is produced, is called by geometers the *side* of the square, but by most arithmeticians the *square root*.

XIX.

A **cube**, again, is that which is equal times equal equally; or one that is contained under three equal numbers.

Diagram. A cube drawn in oblique projection, its edges subdivided into three parts with dots at the grid intersections, illustrating the cube number 27 as a solid three units in every dimension. No vertex letters are printed.

He likewise calls a *cube* that solid number which is equal times equal equally — that is, one whose units, arranged in length, breadth, and depth, represent a geometrical cube, so that all its dimensions (length, breadth, and height or depth) are equal; or one produced by the mutual multiplication of three equal numbers among themselves. Such is the number 27, contained under the equal numbers 3, 3, 3, or generated by their mutual multiplication: for 3 times 3 makes 9, and 9 times 3 yields the cube number 27. All its units, reduced to solid form, represent a perfect geometrical cube, and there are three units in length, in breadth, and in depth alike. Therefore the number 27 is equal times equal equally.

Any one of the three equal numbers under which a cube is contained, or from whose mutual multiplication it is produced, is called by geometers the *side* of the cube, but by most arithmeticians the *cube root*.

XX.

Numbers are **proportional** when the first is the same multiple, or the same part, or the same parts, of the second as the third is of the fourth; or else when the first equally contains the second, and the third the fourth, together with the same part of it or the same parts.

In order to take in proportional numbers in every kind of rational proportion of inequality (which is what all unequal numbers compared with one another are), we have added to this definition the words: *or else when the first equally contains the second, and the third the fourth, together with the same part of it or the same parts*. For Euclid's received definition — which I judge to be corrupt, since it is defective and incomplete — takes in only proportional numbers in multiple or submultiple proportion, and in the remaining proportions of lesser inequality. In multiple proportion any four numbers are proportional when the first is the same multiple of the second as the third is of the fourth; in submultiple, when the first is the same part of the second as the third is of the fourth; and in the remaining proportions of lesser inequality, when the first is the same parts of the second as the third is of the fourth, as Euclid's definition requires. But from it we can by no means detect which numbers are proportional in superparticular proportion, in the superpartient of a multiple-superparticular, and in the multiple-superpartient. For in all of these the first number is neither the same multiple of the second, nor the same part, nor the same parts, as the third is of the fourth; rather the first equally contains the second, and the third the fourth — say either once or several times — together with the same part of it, or the same parts, as is clear from what we taught on definition 4 of book 5, where we set out all the rational proportions fully.

And so these numbers 12, 4, 9, 3 are proportional, since the first is the same multiple of the second as the third is of the fourth, namely triple. Likewise these, 4, 12, 3, 9: for the first is the same part of the second, and the third of the fourth, namely a third. Again, these numbers 6, 8, 9, 12 are proportional, because the first is the same parts of the second, and the third of the fourth, namely three-fourths. Finally, 7, 6, 14, 12 and 7, 4, 14, 8 and 11, 5, 22, 10 and 12, 5, 24, 10 are proportional numbers. For in the first example the first number contains the second, and the third the fourth, once and moreover the same part of it, namely a sixth; in the second, once, and the same parts, namely three-fourths; in the third,

twice, and still the same part, namely a fifth; in the last, twice, and besides the same parts, say two-fifths. But if the first number [is not the same multiple] of the second, and the third of the fourth,

is not the same multiple, nor the same part, nor the same parts; or, finally, if the first does not equally contain the second, and the third the fourth, together with the same part of it or the same parts — then the given numbers must in no way be called proportional.

Therefore, whenever four numbers are set down as proportional, it must necessarily be granted — if the greater are compared with the less — that the first is the same multiple of the second as the third is of the fourth, or else that the first equally contains the second, and the third the fourth, together with the same part or the same parts. And conversely, if it is granted that the first is the same multiple of the second as the third is of the fourth, or that the first is said to contain the second equally, and the third the fourth, together with the same part or the same parts, then the numbers are concluded to be proportional. But if the less are referred to the greater and are said to have the same proportion, it must be admitted that the first is the same part of the second, and the third the same part of the fourth, or the same parts; and conversely, if it is granted that the first is the same part of the second, and the third of the fourth, or the same parts, it is concluded that these numbers have the same proportion.

Euclid defines as proportional only those numbers that have the same proportion of *inequality*. For if we speak of a proportion of equality, it is clear that the first must be equal to the second, and the third to the fourth, for them to be called proportional numbers.

From this definition it is plainly gathered that equal numbers have the same proportion to the same number, and conversely that the same number has the same proportion to equal numbers; and likewise that numbers having the same proportion to the same number, or to which the same number has the same proportion, are equal. For since equal numbers are of the same number either the same multiple, or the same part, or the same parts; or else equally contain it together with the same part of it or parts; and likewise since the same number is of equal numbers either the same multiple, or the same part, or the same parts, or else equally contains them together with the same part of them — it is clear, by this definition, that equal numbers have the same proportion to the same number, and the same number to equal numbers.

Again, since numbers having the same proportion to the same number are of it either the same multiples, or the same part, or the same parts, or else equally contain it together with the same part of it or parts; and likewise since the same number is of them either the same multiple, or the same part, or the same parts, or else equally contains them together with the same part of them or parts — by this same definition it is manifest that numbers which have the same proportion to the same number, or to which the same number has the same proportion, are equal.

By parallel reasoning it is inferred that a greater number has a greater proportion to the same number than a lesser one does; and conversely, that the same number has a greater proportion to a lesser number than to a greater. Likewise, that of two numbers the one which has the greater proportion to the same number is the greater, while the one to which the same number has the greater proportion is the lesser. All of which are clear, provided this definition is rightly understood.

This definition holds good even for fractional numbers, whether whole numbers are entirely absent or not. For these four numbers are proportional: $\frac{2}{3}$, $\frac{1}{3}$, 1, $\frac{1}{2}$ — because the first is the same multiple of the second as the third is of the fourth, namely double, as is plain, if the first two are brought to the same denomination, as to [?], and the latter two likewise to the same denomination, as to [?]. (How fractional numbers are reduced to the same denomination we taught in the *Arithmetic*, and we shall demonstrate it at the end of book 9.) By the same reasoning these four numbers are proportional: 2, 4, $1\frac{1}{2}$, 3 — since the first is the same part of the second, and the third of the fourth, namely a half, as is evident, if the first two are brought to these of the same denomination, [?], and the latter two to these, [?]; and so of the rest.

XXI.

Similar plane and solid numbers are those that have proportional sides.

For one plane number to be similar to another, it is not necessary that any two sides of the one be proportional to any two sides of the other; it is enough that the one have some sides which are proportional to some two sides of the other. For by this reasoning their breadths will be proportional to their lengths, if they are reduced to a plane figure according to their units, as the sides taken are joined. Thus the plane numbers 24 and 6 are similar, since the sides of the former, 6 and 4, are proportional to the sides of the latter, 3 and 2 — although the other sides of the former, namely 8 and 3, or 12 and 2, are not proportional to these same sides.

In the same way, for two solid numbers to be similar, it is not required that any three sides of the one be proportional to any three sides of the other; it suffices that three sides of the one be found proportional to three of the other, because by this reasoning, if they are reduced to solid form according to their units, their breadths will be proportional to their lengths, and their lengths to their heights. Thus the solid numbers 192 and 24 are similar, because the sides of the former, 8, 6, 4, are proportional to the sides of the latter, 4, 3, 2 — even though other sides of the former, namely 12, 8, 2, or 16, 4, 3, are by no means proportional to these same sides.

And so two plane or solid numbers can be similar even though, when some sides of the one are taken, no proportional sides of the other can be found in any way. For the plane numbers 24 and 6 are similar, as has been said; and yet if the sides of the former are taken as 3 and 8, none proportional to them will be found in the latter. So too the solid numbers 192 and 24 are similar, even though when the sides of the former are taken as 3, 4, 16, none proportional to them are found in the latter.

Moreover, this similarity of plane [and solid] numbers is also found among fractional numbers, or among whole numbers together with fractional ones. For if four non-whole proportional numbers are set down, and both the two former and the two latter are multiplied by one another, there will usually be produced two similar non-whole plane numbers, and so on. I said "usually," because it can happen that sometimes whole numbers are generated. For if two sides are $\frac{2}{3}$ and 6, and two others $1\frac{1}{3}$ [?] and 12, which have the same ninefold proportion, the former two will produce the plane number 4, and the latter the number 16.

XXII.

A **perfect number** is one that is equal to its own parts.

That number to which all its parts taken together are equal (we are speaking of *aliquot* parts, according to the definition in this book) is called by mathematicians *perfect*. Of this kind are these numbers: 6, 28, 496. For the first contains only these aliquot parts, 1, 2, 3, which taken together make up the number 6. The aliquot parts of the second number are all these: 1, 2, 4, 7, 14, whose sum constitutes the number 28 itself. The third number has these aliquot parts: 1, 2, 4, 8, 16, 31, 62, 124, 248 —

— all of which, collected into one sum, evidently make up the number 496. Which numbers are perfect, and by what method and principle they are generated (for

besides the three mentioned there are innumerable others), will be demonstrated by Euclid in the last proposition of book 9.

But if all the aliquot parts of some number taken together are greater than the number itself, that number is usually called *abundant*; if less, *deficient*.

It is gathered from this passage, more clearly than daylight, that "part" is taken by Euclid only in the sense of an aliquot part. For otherwise every number would be perfect, being equal to its own parts, if any lesser number could be called a part of a greater number whether it measures it or not.

To these definitions set out by Euclid, it seems to me that some others should be added from Campanus and other writers; and immediately after these will follow postulates and common notions [axioms], especially those which both Euclid and his interpreters seem to use in demonstrating the properties of numbers.

XXIII.

A **number** is said to *measure* a number by that number which — multiplying it, or being multiplied by it — produces it.

For example, the number 4 is said to measure the number 12 by 3, because when multiplied by 3 it produces 12. And by the same reasoning the number 3 measures the same number 12 by 4, since from the multiplication of 4 by 3 the number 12 is produced. That this is so will become clear by the following reasoning: since the number 4 measures 12 by 3, 4 makes up 12 itself, taken as many times as there are units in 3. Therefore, by definition 15, the number 3 multiplying the number 4 will produce 12. But since, as we shall show in proposition 16 of this book, the same number is produced from multiplying 4 by 3 as from 3 by 4, it remains manifest that the same number 12 is generated if the number 4 multiplies the number 3.

This definition also fits non-whole numbers. For the number 2[?] is said to measure the number 13[?] by 5[?], because when multiplied by 5[?] it produces 13[?].

XXIV.

Proportion of numbers is a certain relation of one number to another, according to which it is a multiple of it, or a part or parts of it; or else contains it once or several times, together with some part of it or parts.

If the number 20 is compared with the number 4 in respect of that by which it is a multiple of it — namely fivefold — this relational comparison will be called a *proportion*. So too a proportion is the relation by which the same number 20 is compared with the number 60, according to which it is a third part of it; and so of the rest.

Since this is so, it is clear that four numbers are called proportional only when the first is the same multiple of the second as the third is of the fourth, or the same part, or the same parts; or else when the first equally contains the second, and the third the fourth, together with the same part of it or the same parts, as we taught above at definition 20.

XXV.

The **terms**, or *roots*, of a proportion are the two numbers than which no smaller can be taken in the same proportion.

XXVI.

When three numbers are proportional, the first is said to have to the third the **duplicate ratio** of that which it has to the second. And when four numbers are proportional, the first is said to have to the fourth the **triplicate ratio** of that which it has to the second; and so on continuously, one more each time, as long as the proportion continues.

This definition, as it applies to magnitudes, was fully explained at definition 10 of book 5. Since everything we wrote there can easily be transferred to numbers here, there is no reason to repeat it again.

XXVII.

Given any numbers set in order, the proportion of the first to the last is said to be **compounded** of the proportions of the first to the second, of the second to the third, of the third to the fourth, and so on, as long as the proportion continues.

That this is so we have demonstrated at length at definition 5 of book 6. Here too may be referred those definitions handed down in the fifth book concerning alternate ratio and inverse ratio; concerning the composition, division, and conversion of a ratio; concerning ratio *ex aequali* [ratio of equality]; and concerning ordered and perturbed proportion. For all these modes of argument that deal with proportions will be shown to apply also to the proportions of numbers in this seventh book.

Euclid, Book VII (Arithmetic) — Postulates, Axioms, and Propositions 1–2

(*Clavius's commentary on the Elements**. Enunciations of the postulates, axioms, and propositions are set as blockquotes; Clavius's demonstrations and scholia follow in ordinary prose. Lettered marginal references keyed to the superscript letters of a demonstration are given as [Margin: ...]; "pron." = pronuntiatum/axiom, "septi." = Euclid,* *Elements VII.*)

POSTULATES, OR REQUESTS [POSTVLATA, SIVE PETITIONES]

I.

Let it be postulated that, for any number, any number of numbers equal to it, or multiples of it, can be taken.

II.

That a greater number than any given number can be taken.

Clavius's note: For although a number cannot be diminished infinitely — rather, the diminution necessarily arrives at the indivisible unit — nevertheless it can be increased infinitely by the continual addition of a unit. Therefore, for any proposed number a greater one can be exhibited, namely the one that arises from the addition of a single unit, or even of several.

AXIOMS, OR PRONOUNCEMENTS [AXIOMATA, SIVE PRONVNTIATA]

I.

Numbers that are equal multiples of equal numbers, or of the same number, are equal to one another.

II.

Numbers of which the same number is an equal multiple, or of which equal numbers are equal multiples, are equal to one another.

III.

Numbers that are the same part, or the same parts, of equal numbers, or of the same number, are equal to one another.

IV.

Numbers of which the same number, or equal numbers, are the same part or the same parts, are equal to one another.

V.

The unit measures every number by the units that are in it — that is, by the very number itself.

Clavius's note: For the unit, taken as many times as there are units in the proposed number, constitutes that number. It therefore measures the number by the units contained in it — that is, by the very number made up of its own units.

VI.

Every number measures itself by the unit.

Clavius's note: Since any number taken once is equal to itself, it is clear that every number measures itself by the unit.

VII.

If a number, multiplying a number, produces some number, the multiplier measures the product by the multiplicand, and the multiplicand measures the same product by the multiplier.

Clavius's note: For let the number A, multiplying the number B, produce the number C. I say that A measures C by B, and that B measures the same C by A. For since, by definition 15, the number B — repeated as many times as there are units in A — constitutes C, it is clear that B measures C by A; and by the same reasoning A measures that same C by B, since B too, multiplying A, produces the number C, as will be demonstrated in Proposition 16 of this book.

Diagram. A number-line figure of dotted segments standing for numbers, illustrating Axiom VII.

- Upper line: labelled **A** at the left, then **B** partway along (two dotted numbers, A the multiplier and B the multiplicand).
- Lower line: labelled **C** at the left, a longer dotted segment (the product).

VIII.

If a number measures a number, then the number by which it measures will also measure that same number by the units that are in the measuring number — that is, by the measuring number itself.

Clavius's note: For example, since the number 6 measures the number 18 by 3, the number 3 will also measure that same number 18 by 6 — that is, by the units found in the measuring number 6. That this is so we shall confirm in the following way. Since 6 measures 18 by 3, the number 18 will result from the multiplication of 6 by 3, or of 3 by 6, by definition 23. Therefore, by the preceding axiom, the number 3 will measure the number 18 by 6.

IX.

If a number measuring a number multiplies the number by which it measures, or is multiplied by it, it will produce the number it measures.

Clavius's note: For let the number A measure the number C by B. I say that A, multiplying B — or being multiplied by B — produces C. For a number A is said to measure a number C by that number which, when A multiplies it (or by which A is multiplied), produces C, by definition 23. Since, then, A is supposed to measure C by B, it is clear that A, multiplying B (or being multiplied by it), produces C.

Diagram. A dotted-segment figure illustrating Axiom IX.

- Upper line: **A** at the left, then **B** partway along.
- Lower line: **C** at the left, a longer dotted segment.

X.

A number measuring any number of numbers also measures the number composed of them.

Clavius's note: Let the number A measure the numbers BC and CD. I say that the same A also measures BD, which is composed of them. For since A measures BC and CD, each of BC and CD will be a multiple of A. Therefore, when BC is divided into the parts BE and EC [recte: EC], equal to A, and CD into the parts CF, FG, GD, equal to the same A, the number BD — composed of all the parts BE, EC, CF, FG, GD, equal to A — will be a multiple of A. Therefore A measures BD. Which is the thing proposed.

Diagram. A dotted-segment figure illustrating Axiom X.

- Upper line: **A** (the measuring number), a short dotted segment.

- Lower line: the composite segment marked, in order, **B ... E ... C ... F ... G ... D** [final endpoint engraved ambiguously; the text's composition "BE, EC, CF, FG, GD" of the whole BD requires **D**]. BC is divided at E; CD is divided at F and G.

XI.

A number measuring any number also measures every number that the latter measures.

Clavius's note: Let the number A measure the number B, and B measure the number CD. I say that the same A also measures the number CD, which B measures. For since B measures CD, CD will be a multiple of B. Therefore, when CD is divided into the parts CE and ED, equal to B, A will measure the numbers CE and ED, since it is supposed to measure the number B, which is equal both to CE and to ED. Therefore the same A, by pronuntiatum 10, also measures the number CD, composed of CE and ED. Which is the thing proposed.

Diagram. A dotted-segment figure illustrating Axiom XI.

- First line: **A**, a short dotted segment.
- Second line: **B**, a longer dotted segment.
- Third line: **C ... E ... D**, with E dividing CD into CE and ED.

XII.

A number measuring the whole and the part taken away also measures the remainder.

Clavius's note: Let the number A measure the whole BC and the part taken away BD. I say that the same A also measures the remainder DC. For since A measures both BC and BD, each of BC and BD will be a multiple of A, or else ED [recte: BD] will be equal to A itself. Therefore, when both BC and BD are divided into parts equal to A, the remaining number DC will be either one part of the number BC equal to A, or several — and so DC will be either equal to A or a multiple of it. Therefore A measures DC. Which is the thing proposed.

Diagram. A dotted-segment figure illustrating Axiom XII, showing three cases of the segment BC with the point D at different positions.

- Top line: **A**, a short dotted segment.
- Line 1: **B ... D ... C** (D near C).
- Line 2: **B ... D ... C** (D closer to the middle).

- Line 3: **B ... D ... C** (D near B).

THEOREM 1. PROPOSITION 1. [THEOR. 1. PROPOS. 1]

If, two unequal numbers being set out, the lesser is continually subtracted from the greater in a certain alternating subtraction, and the remainder never measures the number preceding it until a unit is reached, then the numbers set out at the beginning are prime to one another.

Let two unequal numbers AB and CD be set out, of which the lesser, CD, is subtracted from the greater, AB, as many times as possible; and let the remainder EB be subtracted from CD as many times as possible; and the remainder FD from EB. And suppose that in this alternating subtraction the remainder never measures the preceding number, from which it was subtracted, until the subtraction arrives at the unit GB — which indeed measures the preceding number FD. I say that the numbers AB and CD are prime to one another; that is, that only the unit measures them as a common measure.

For if they are not said to be prime to one another, some number, other than the unit, will measure them as a common measure; let it be H. Now since H measures the number CD, and CD measures the number AE (because CD is either a part of AE or equal to it, seeing that when it was subtracted from AB it left the number EB), [Margin: (a) 11.pron.] H will also measure AE. But H measures the whole AB as well. [Margin: (b) 12.pron.] Therefore it also measures the remainder EB. Now EB measures CF. [Margin: (c) 11.pro.] Therefore H will measure CF as well; and consequently, since it also measures the whole CD, [Margin: (d) 12.pron.] it will also measure the remainder FD. Since, then, FD measures EG, [Margin: (e) 11.pron.] H will also measure FG. But H was also measuring the whole EB. [Margin: (f) 12.pron.] Therefore the number H will also measure the remaining unit GB — the part [measuring] the whole. Which is absurd. Therefore no number other than the unit will measure the numbers AB and CD; and so they are prime to one another. And so, if, two unequal numbers being set out, etc. Which was to be demonstrated.

Diagram. A dotted-segment figure for Proposition 1 (anthyphairesis).

- Line 1: **A ... E ... G ... B** (the greater number AB, with the successive remainder-points E and G, and G · B the terminal unit).
- Line 2: **C ... F ... D** (the lesser number CD, with F).
- Line 3: **H** — (a short solid segment: the supposed common measure).

SCHOLIUM

We shall convert this proposition, together with Campanus, in the following way:

If, two numbers prime to one another being set out, the lesser is always subtracted from the greater in a certain alternating subtraction, the remainder will never measure the preceding number until a unit is reached.

Let AB and CD be two numbers prime to one another, of which the lesser, CD, is subtracted from the greater, AB, as many times as possible; and the remainder EB from CD, as many times as possible; and the remainder FD from EB, leaving GB. I say that in this alternating subtraction the remainder never measures the preceding number, until a unit is reached.

For, if it were possible, let the remainder GB — before the subtraction reaches the unit — measure the preceding number FD taken away from EB. Since, then, the number GB measures the number FD, and FD measures EG, [Margin: (g) 11.pron.] GB will also measure EG. And since GB measures itself as well, [Margin: (h) 10.pron.] it will also measure the number EB, composed of EG and GB. But EB measures CF; [Margin: (i) 11.pron.] therefore GB will also measure that same CF. And further, since it is supposed to measure FD as well, [Margin: (k) 10.pro.] it will also measure CD, composed of CF and FD. But CD measures AE; [Margin: (l) 11.pron.] therefore it will also measure that same AE, as has been shown; [Margin: (m) 10.pron.] and it will also measure AB, composed of both AE and EB. Therefore, since the number GB measures both numbers AB and CD, they will be composite to one another. Which is absurd, since they are supposed to be prime to one another. Therefore no remaining number will ever measure the preceding one, until a unit is reached. Which is the thing proposed.

In the same way this too is true:

If, two numbers composite to one another being set out, the lesser is always subtracted from the greater in a certain alternating subtraction, the subtraction will not reach the unit, but [will reach] a number that measures the preceding subtracted number.

Clavius's note: For if a subtraction of this kind reached all the way to the unit, the numbers set out would be prime to one another, [Margin: (n) 1.septi. — Euclid, *Elements* VII.1] as Euclid demonstrated. Which is absurd, since they are supposed to be composite to one another.

From these things we shall easily discern whether any two given numbers are prime to one another or not. For, when the lesser is always subtracted from the greater in a certain alternating subtraction, if the remainder never measures the preceding number until a unit is reached, they will be prime to one another, [Margin: (o) 1.septi. — Euclid, *Elements* VII.1] as Euclid demonstrated. But if some remaining number does measure the preceding one, they will be composite to one another, since that same remaining number measures both of the given numbers, as is clear from the earlier demonstration of this scholium. For from the fact that the remaining number GB was said to measure the preceding number FD, it was shown that this same remainder GB measures both AB and CD.

PROBLEM 1. PROPOSITION 2. [PROBL. 1. PROPOS. 2] [Margin: ii.]

Given two numbers not prime to one another, to find their greatest common measure.

Let two numbers AB and CD, not prime to one another, be given, whose greatest common measure is required. Let the lesser, CD, be subtracted from the greater, AB, as many times as possible, leaving the number EB; let EB, subtracted from CD, leave FD; and so on in turn, the lesser always subtracted from the greater in a certain alternating subtraction. In this process one will arrive at a number that measures the one preceding it. For if one arrived at the unit, [Margin: (a) 1.septi. — Euclid, *Elements* VII.1] the numbers AB and CD would be prime to one another, which is contrary to the hypothesis. Suppose, then, that we have now arrived at the remaining number FD, which, subtracted from EB, leaves nothing but measures it. I say that FD is the greatest common measure of the numbers AB and CD.

That it measures both, we shall show as follows. Since FD measures EB, and EB measures CF, [Margin: (b) 11.pro.] FD will also measure CF; and since it also measures itself, [Margin: (c) 10.pro.] it will also measure the whole CD, composed of CF and FD. But CD measures AE. [Margin: (d) 11.pron.] Therefore FD will also measure that same AE. And since FD measures EB as well, [Margin: (e) 10.pron.] it will also measure the whole AB, composed of both AE and EB. Therefore FD measures both numbers AB and CD.

That FD is their greatest common measure, we shall prove thus. If it were possible, let there be a common measure G greater than FD. Since, then, G measures both AB and CD, and CD measures AE, [Margin: (f) 11.pron.] G will also measure AE, [Margin: (g) 12.pron.] and therefore the remainder EB as well. But

EB measures CF; [Margin: (h) 11.pron.] therefore G will also measure that same CF, [Margin: (i) 12.pron.] and therefore the remainder FD as well — the greater measuring the smaller. Which is absurd. Therefore no number greater than FD measures the numbers AB and CD; and so FD is the greatest measure of the numbers AB and CD.

But if the lesser number CD measures the greater AB — so that, subtracted from AB, it leaves nothing — then CD itself will be the greatest common measure of both, since it also measures itself, as appears in this figure. Therefore, given two numbers not prime to one another, etc. Which was to be done.

Diagram. The principal dotted-segment figure for Proposition 2.

- Line 1: A ... E ... B (the greater number AB, with the remainder-point E).
- Line 2: C ... F ... D (the lesser number CD, with F).
- Line 3: G — (a short solid segment: the supposed greater common measure).

Diagram. A second dotted-segment figure for Proposition 2, for the case in which the lesser number measures the greater directly.

- Line 1: A ... B (a dotted segment).
- Line 2: C ... D (a shorter dotted segment measuring the first).

COROLLARY [COROLLARIUM]

From this it is evident that a number measuring two numbers also measures their greatest common measure.

Clavius's note: This is drawn from that part of the demonstration in which it was shown that FD is the greatest measure of AB and CD. For it was demonstrated there that the number G, if it measures the numbers AB and CD, also measures the number FD, their greatest common measure. And the same reasoning holds for the rest.

SCHOLIUM

From what has been said, we can easily test, together with Campanus, whether any given numbers are prime to one another or not. For let there be three numbers A, B, C. First, then, I test — by the method we taught at Proposition 1 — whether the two A and B are prime to one another. If they are prime to one another, the three numbers A, B, C will not be composite among themselves, since

they can have no common measure other than the unit, on account of the numbers A and B being prime to one another.

Diagram. A dotted-segment figure of three numbers for the scholium.

- Line 1: **A**, a dotted segment.
- Line 2: **B**, a shorter dotted segment.
- Line 3: **C**, a shorter dotted segment still.

*[Continues Euclid **Book VII** (arithmetic). This opening continues the scholium begun on the previous page — the extension of the "prime-to-one-another" test to three numbers.]*

but if A and B are composite to one another, [Margin a: 2.septi. — Elements VII.2] let their greatest common measure D have already been found. If this D also measures the number C, it is clear that the three numbers A, B, C are composite to one another, since they have the number D as a common measure.

A
 B
 C
 D ...

But if D, the greatest measure of A and B, does not measure C, then C and D are either prime to one another or not. If they are prime to one another, the three numbers A, B, C will not be composite to one another, but prime to one another. For suppose they were said to be composite to one another, so as to have a common measure: that common measure would then measure the number D, the greatest measure of A and B, by the corollary of this proposition; and therefore, since that same measure also measures C, the numbers C and D would not be prime to one another — which is contrary to the hypothesis.

A
 B
 C
 D ...

But if C and D are not prime to one another, then the three numbers A, B, C are composite to one another. [Margin b: 2.septi. — Elements VII.2] For once the greatest common measure of C and D — call it E — has been found: since E measures D, and D in turn measures A and B, [Margin c: 11.pron. — Axiom 11 of this book] E too will measure those same A and B. Therefore, since this same E likewise measures C, E measures the three numbers A, B, C; and so they are composite to one another. Which is what was proposed.

A
 B
 C
 D E ..

By a similar method we shall test whether more than three numbers are prime to one another, or rather composite to one another. For if the given numbers are four, we must first carry out the test on three of them; if five, on four; and so on. The remaining steps are to be completed just as we described for three given numbers.

PROBL. 2. PROPOS. 3.

[Margin: iii.]

Given three numbers not prime to one another, to find their greatest common measure.

Let three numbers A, B, C be given, not prime to one another, whose greatest common measure is to be found. Let D be the greatest measure of A and B. If, then, D also measures C, it is clear that D is the greatest measure of the given numbers A, B, C. For if some greater number were said to measure A, B, C, that same number would — by the corollary of Proposition 2 of this book — measure D, the greatest measure of A and B: a greater number measuring a lesser, which is absurd.

But if D does not measure C, then at least D and C are composite to one another. For since A, B, C are composite to one another, any common measure of theirs will — by the corollary of Proposition 2 of this book — measure D, the greatest measure of A and B; and since that same measure also measures C, D and C are composite to one another. [Margin a: 2.septi. — Elements VII.2] Let their greatest measure be E. I say that E is the greatest common measure of the given numbers A, B, C. That it is a common measure of theirs is shown as follows. Since E measures the numbers C and D, and D measures A and B, [Margin b: 11.pro. — Axiom 11 of this book] E too will measure A and B; and so it will measure the three numbers A, B, C.

A
 B D
 C E .. F—

That E is their *greatest* common measure is also clear. For, if it were possible, let F be a common measure of theirs greater than E. Since, then, F measures A and B, it will also — by the corollary of Proposition 2 of this book — measure D, their

greatest common measure; and it also measures C. Therefore F, measuring D and C, will — by the same corollary — measure E, their greatest measure: a greater number measuring a lesser, which is absurd. So no number greater than E measures A, B, C; and therefore E is their greatest measure. And so, given three numbers not prime to one another, and so forth. Which was to be done.

COROLLARIVM.

From this it is clear that a number which measures three numbers also measures their greatest common measure.

This is also gathered from the last part of the demonstration. For it was shown there that the number F, if it measures A, B, C, also measures E, their greatest common measure; and the same reasoning holds in all other cases.

By like reasoning, when more than three numbers are given, not prime to one another, their greatest common measure will be found, and this same corollary will hold. For if the given numbers are four, the greatest common measure of three of them must first be found; if five, the greatest common measure of four must first be taken; and so on. All the rest is to be carried out as was said for three numbers.

THEOR. 2. PROPOS. 4.

[Margin: iiii.]

Every number is, of every number — the less of the greater — either a part or parts.

Let there be two numbers, A the less and B the greater. I say that A is either a part or parts of B. First, let A and B be prime to one another. Since, then, every unit of the number A is a part of the number B, it is clear that the number A is parts of the number B — namely, as many parts as there are units in A.

A
B

Next, let A and B not be prime to one another, but composite to one another, and let A measure B. On this supposition it is manifest that A is a part of the number B, by Definition 3 of this book.

A
B

**

But now let A not measure B. [Margin a: 2.septi. — Elements VII.2] Let their greatest common measure be C, and let the number A be divided into the parts AD, DE, EF, each of them equal to C. [Margin b: 3.defin. — Definition 3 of this book] Since, then, C is a part of B (because it measures it), AD too will be a part of that same B; and likewise DE and EF. And therefore the whole number A is parts of the number B — namely, as many as the number of times C is contained in AF. Every number, then, is of every number — the less of the greater — either a part or parts. Which was to be demonstrated.

A .. D .. E .. F
 B
 C ..

THEOR. 3. PROPOS. 5.

[Margin: v.]

If a number be a part of a number, and another the same part of another: then also the two together will be the same part of the two together as the one is of the one.

Let the number A be the same part of the number BC as the number D is of the number EF. I say that both numbers A and D together are the same part of both numbers BC and EF together as A is of BC, or D is of EF. For let the numbers BC, EF be divided into the parts BG, GC; EH, HF, equal to A and D. Then the multitude of the parts of the number BC will be equal to the multitude of the parts of the number EF, because A is the same part of BC as D is of EF. Since, then, A and BG are equal, if there be added to them the equals D and EH, A and D together will be equal to BG and EH together; and by the same argument A and D together will be equal to GC and HF together. And so on in turn: if there be more parts in BC, EF, the sum of the numbers A and D will be equal to as many aggregates of the parts of the numbers BC and EF as the number of times A is contained in BC, or D in EF. And therefore both A and D together are the same part of both BC and EF together as A is of BC, or D is of EF. If, then, a number be a part of a number, and so forth. Which was to be shown.

A D
 B G C E H F

SCHOLIVM.

The same holds true in fractional numbers, and precisely the same demonstration will apply. This appears in the following example, where the

number A is the same part of the number BC, and the number D of the number EF; and accordingly both A and D together will be shown to be the same part of both BC and EF together as A is of BC — provided, of course, that BC and EF are divided into parts BG, GC, EH, HF equal to A and D, and so on.

A, $\frac{2}{7}$ D, $\frac{2}{7}$

B, $\frac{2}{7}$ G, $\frac{2}{7}$ C E, $\frac{2}{7}$ H, $\frac{2}{7}$ F

Now if it should ever happen that a fractional number cannot be divided into the proposed equal parts, because its numerator cannot be split into those parts, then both numerator and denominator must be multiplied by the number of parts. For by this method there will be produced another fraction equivalent to the first, and one whose numerator can be divided into the proposed parts. Thus, if the fraction $\frac{5}{9}$ is to be cut into two equal parts, each of its numbers is to be multiplied by 2; if into three, by 3; if into four, by 4; and so on. In this way there are generated the fractions $\frac{10}{18}$, $\frac{15}{27}$ [?], $\frac{20}{36}$ — of which the first will be cut into these two equal parts, $\frac{5}{18}$, $\frac{5}{18}$; the second into these three, $\frac{5}{27}$, $\frac{5}{27}$, $\frac{5}{27}$ [?]; and the third into these four, $\frac{5}{36}$, $\frac{5}{36}$, $\frac{5}{36}$, $\frac{5}{36}$.

Again, when there are whole numbers present, they must first be reduced together with the fraction to a single fraction; then, in the same way, both numerator and denominator must be multiplied by the number of parts, and so on. Thus, if the number $4\frac{2}{7}$ is to be cut into three parts, we first reduce it to this single fraction, $\frac{30}{7}$; then we multiply each of its numbers by 3, so that there results the fraction $\frac{90}{21}$, of which the three equal parts are $\frac{30}{21}$, $\frac{30}{21}$, $\frac{30}{21}$. And these same rules are to be observed in the following propositions too, whenever they are applied to fractions; and by the name "fractions" whole numbers combined with fractions are always to be understood as well, and likewise the cases where some are fractional and others whole.

In the same way we shall demonstrate what follows.

If a unit be a part of a number, and another unit, or a number, the same part of another number: then also both the units together, or the unit and the number together, will be the same part of both numbers together as the unit is of the number.

This appears clearly in the examples set out here, for the demonstration is exactly the same.

A. D. A. D...

B. G. C E. H. F B. G. C E... H... F

We can also extend this proposition to any number of numbers, in this way.

If there be any number of numbers, equal in multitude to any number of others, each of each the same part: then also all of them together will be the same part of all together as the one is of the one.

Let the numbers A, B, C be, each of each, the same part of the numbers DE, FG, HI. I say that all the numbers A, B, C together are the same part of all the numbers DE, FG, HI together as A is of DE. For let the numbers DE, FG, HI be divided into parts equal to A, B, C.

A B . . . C . .
D . . . K . . . E F . . . L . . . G H . . M . . I

Then the multitude of the parts of the number DE will be equal to the multitude of the parts both of the number FG and of the number HI. Since, then, A and DK are equal, if there be added to them the equals B and FL, A and B together will be equal to DK and FL together; and if to these there be again added the equals C and HM, then A, B, C together will also be equal to DK, FL, HM together. By like reasoning A, B, C will be equal to KE, LG, MI together; and so on in turn. If there be more parts in DE, FG, HI, the sum of the numbers A, B, C will be equal to as many aggregates of the parts of the numbers DE, FG, HI as the number of times A is contained in DE. Therefore A, B, C together are the same part of DE, FG, HI together as A is of DE.

**

The same follows if, in place of one of the numbers A, B, C, a unit be taken, or in place of several, or even of all of them, several units, as was said in the case of two. This is what the following figures indicate.

A. B. . C. . .
D.K.E. F. . L. . G H. . . M. . . I

A. B. C.
D.K.E F.L.G H.M.I

These things hold also for fractional numbers. For if any number of fractional numbers be, each of each, the same part of any number of fractional numbers equal in multitude, then all together will be the same part of all together as the one is of the one. This will be demonstrated in the same way, even if some of the numbers are whole numbers or units, as may be seen here.

A, 1 B, $\frac{1}{2}$ C, $\frac{1}{3}$ [?]
D 1 K 1 E F $\frac{1}{2}$ L $\frac{1}{2}$ G H $\frac{1}{3}$ M $\frac{1}{3}$ I

We shall also propose something similar to the first theorem of the fifth book, in this manner.

If there be any number of numbers, equal in multitude to any number of others, each of each equimultiples: as one number is a multiple of one, so will all together be of all together.

The demonstration is the same here as in Book 5. Nevertheless we shall also demonstrate it otherwise, thus. Let A, B, C be numbers that are equimultiples, each of each, of the numbers D, E, F. I say that all of A, B, C together are the same multiple of all of D, E, F together as A is of D. For since A is the same multiple of D as B is of E, and C of F, then conversely D will be the same part of A as E is of B, and F of C. Therefore, by what we have just demonstrated, D, E, F together will be the same part of A, B, C together as D is of A; and accordingly, conversely, all of A, B, C together are the same multiple of all of D, E, F together as A is of D.

A B C
D E ... F ..

If the numbers A, B, C are fractional, and equimultiples of their fractional numbers D, E, F, then, since the multiple of one is one, all together are also multiples of all together — as is clear from the demonstration.

But if, in place of one of the numbers D, E, F, a unit be assumed — or, in place of several or of all, several units — the theorem will be demonstrated in the same way, as appears from the following figures.

A .. B C A .. B .. C ..
D · E .. F ... D · E · F ·

THEOR. 4. PROPOS. 6.

[Margin: vi.]

If a number be parts of a number, and another the same parts of another: then also the two together will be the same parts of the two together as the one is of the one.

Let the number AB be the same parts of the number C as the number DE is of the number F. I say that both numbers AB and DE together are the same parts of both numbers C and F together as AB is of C, or DE is of F. For let the numbers AB, DE be divided into parts AG, GB; DH, HE, that are parts of the numbers C and F. Then the multitude of parts in the number AB will be equal to the multitude of parts in the number DE, because AB is the same parts of the number C as DE is of the

number F. Since, then, the part that AG is of the number C, that same part is DH of the number F, [Margin a: 5.septi. — Elements VII.5] both AG and DH together will be the same part of both C and F together as AG is of C, or DH is of F. By the same reasoning, both GB and HE together will be the same part of both C and F together as GB is of C, or HE is of F. And so on in turn: if there be more parts in AB, DE, there will be as many aggregates of parts contained in the numbers AB, DE, each of which is the same part of the numbers C, F together as AG is of C, as there are equal parts that the number AB is of C, or DE is of F. And accordingly both numbers AB and DE together are the same parts of both numbers C and F together as AB is of C, or DE is of F. If, then, a number be parts of a number, and so forth. Which was to be demonstrated.

A ... G ... B D H E
C F

SCHOLIVM.

This same proposition holds in fractional numbers, together with its demonstration, as this example shows.

A, $\frac{1}{5}$ G, $\frac{1}{5}$ B D, $\frac{2}{7}$ H, $\frac{2}{7}$ E
C, $\frac{3}{5}$ F, $\frac{6}{7}$

But we shall also amplify this proposition, extending it to any number of numbers, whether whole or fractional, in this way.

If there be any number of numbers, of any number of numbers, each of each the same parts: then also all together will be the same parts of all together as the one is of the one.

For the demonstration is the same, if only, in place of the fifth proposition, we assume what we demonstrated in the second place in the preceding scholium; and here it is clear.

A .. K .. B C ... L ... D E M F
G G I

THEOR. 5. PROPOS. 7.

[Margin: vii.]

If a number be a part of a number, such as a subtracted number is of a subtracted number: then the remainder will be the same part of the remainder as the whole is of the whole.

Book VII

THEOR. 5. PROPOS. 7. (continued) [Margin: vii.]

Demonstration. Let the number AB be the same part of the number CD that the subtracted AE is of the subtracted CF. I say that the remainder EB is the same part of the remainder FD that the whole AB is of the whole CD.

For let EB be made the same part of the number GC that AE is of CF — that is, the same part that the whole AB is of the whole CD. Now since AE is the same part of CF that EB is of GC, [Margin: a — Elements VII.15] the two together, AE and EB, are the same part of the two together, CF and GC, that AE is of CF — that is, that the whole AB is of the whole CD. And therefore, since AB is the same part of each of the whole segment FG (that is, of CF together with GC) and of CD, the segments FG and CD are equal to one another. So when the common CF is removed, the remainders GC and FD are left equal. Therefore EB is the same part of FD that it is of GC — that is, that the whole AB is of the whole CD. Therefore, if a number is a part of a number, and so on. Which was to be shown.

A.... E... B G.... C..... F.... [Margin: a — Elements VII.15]

SCHOLIUM

This proposition, together with its demonstration, holds also for fractional numbers, as is clear here:

A, $\frac{3}{8}$. E, $\frac{2}{5}$ [?]. B, G, $\frac{4}{5}$. C, $\frac{6}{8}$. F, $\frac{4}{5}$ [?]. D,

This same theorem is true both in whole numbers and in fractions, even when the subtracted amount AE is a unit, or when the remainder EB is a unit, or finally when both the subtracted amount and the remainder in whole numbers are units — as is clear from these examples:

A. E... B | A... E. B | A. F. B G.... C.. F..... D | G.. C..... F.. D | G.. C..
F. D

Moreover, from this we shall demonstrate something similar to the fifth theorem of Book V, both in whole numbers and in fractions:

If a number is the same multiple of a number as a subtracted number is of a subtracted number, then the remainder also will be the same multiple of the remainder that the whole is of the whole.

This we shall show in exactly the same way as that theorem of Book V. But we shall confirm the same result from what has already been demonstrated, as

follows. Let the whole AB be the same multiple of the whole CD as the subtracted AE is of the subtracted CF. I say that the remainder EB is the same multiple of the remainder FD that the whole AB is of the whole CD. For since AB and AE are, conversely, the same part of CF that the subtracted CF is of the subtracted AE — [Margin: b — Elements VII.7] wherefore the remainder FD is also the same part of the remainder EB that the whole CD is of the whole AB. And accordingly, conversely, EB is the same multiple of FD that AB is of CD, which is a multiple.

A..... E.... B C... F.. D [Margin: b — Elements VII.7]

And if from CD a unit CF is subtracted, or if the remainder FD is a unit, or finally if both in whole numbers the subtracted amount CF is a unit and the other remainder FD is a unit, the same is demonstrated, as these examples show together:

A... E..... | A.... E.. B | A.... E.... B C. F.. D | C.. F. D | C. F. D

THEOR. 6. PROPOS. 8. [Margin: viij.]

If a number is the same parts of a number as a subtracted number is of a subtracted number, then the remainder will be the same parts of the remainder that the whole is of the whole.

Demonstration. Let the number AB be the same parts of the number CD that the subtracted AE is of the subtracted CF. I say that the remainder EB is the same parts of the remainder FD that the whole AB is of the whole CD. For let a number GH be taken equal to AB; then GH will be the same parts of CD that AE is of CF. So let GH be divided into the parts GI, IH that measure CD, and AE into the parts AK, KE that measure CF; then the multitude of the parts GI, IH will be equal to the multitude of the parts AK, KE, and each of GI and IH will be the same part of CD that each of AK and KE is of CF.

Now since CD is a greater number than CF, each of GI and IH — being a part of CD — will be greater than each of AK and KE, which is a part of CF. So let numbers GL, IM be taken equal to AK, KE; then GL will be the same part of CF that AK is of the same CF — that is, the part that GI is of CD. And accordingly, since the whole GI is the same part of the whole CD that the subtracted GL is of the subtracted CF, [Margin: a — Elements VII.7] the remainder LI will also be the same part of the remainder FD that the whole GI is of the whole CD. By the same argument we shall show that MH is the same part of FD that the whole IH is of CD.

A..... K..... E.... B C..... F..... D G..... L.. I..... M.. H
[Margin: a — Elements VII.7]

Since, therefore, each of GI and IH is the same part of FD, both GI and IH together will be the same parts of FD that both LI and MH are; the same parts of CD, that is, that AB is of the same CD, on account of the equality of the numbers AB and GH. Therefore both LI and MH together will also be the same parts of FD that AB is of CD. But since, if from the equals AB and GH the equals AK, KE and GL, IM are taken away, the remainders EB and LI, MH together are equal, the remainder EB will also be the same parts of the remainder FD that the whole AB is of the whole CD — namely, the same parts that LI and MH together were of the same FD. Therefore, if a number is the same parts of a number, and so on. Which was to be shown.

SCHOLIUM

In fractional numbers this same proposition will be demonstrated in exactly the same way, as is here evident:

A, $\frac{2}{19}$. K, $\frac{2}{19}$. E, $\frac{6}{19}$. B C, $\frac{6}{19}$. F, $\frac{9}{19}$. D G, $\frac{2}{19}$. L, $\frac{3}{19}$. I, $\frac{2}{19}$ [?].
M, $\frac{3}{19}$. H

Euclid did not demonstrate this proposition in the way he did the preceding one — as some interpreters do — because here it was not established that the remaining number EB is the same parts of some number that the number AE is of the number CF, [p. 320] whereas there it was evident that the remainder EB is the same part of some number that AE is of CF. For one may take the double of EB, or the triple, quadruple, and so on, until EB becomes a submultiple of the assumed number GC in the same way that AE is a submultiple of CF.

THEOR. 7. PROPOS. 9. [Margin: ix.]

If a number is a part of a number, and another the same part of another; then, conversely, whatever part or parts the first is of the third, the second will be the same part or parts of the fourth.

Demonstration. Let the number A be the same part of the number D that the number BC is of the number EF, and let A, BC be smaller than D, EF, each than each — for the proposition is to be understood of these. I say that, conversely, A is the same part, or the same parts, of D that BC is of EF. For when the numbers BC, EF are divided into the parts BG, GC and EH, HF equal to A and D respectively, the multitude of the parts of BC will be equal to the multitude of the parts of EF. And since BG, GC are equal to one another and smaller than EH, HF (which are likewise equal to one another) — because the whole BC is supposed smaller than the whole EF — BG will be the same part or parts of EH that GC is of HF. [Margin: a — Elements VII.5 or 6] Wherefore both BG, GC together, namely BC, will be the

same part or parts, second of the two, that EH, HF together, namely EF, are; that is, the same that A, the first, is of D, the third. Therefore, if a number is a part of a number, and so on. Which was to be demonstrated.

A.... B.... G.... C D..... E..... H..... F [Margin: a — Elements VII.5 or 6]

SCHOLIUM

In fractional numbers this proposition, together with its demonstration, also holds good, as is here evident:

A, $\frac{3}{11}$. B, $\frac{3}{11}$. G, $\frac{3}{11}$. C D, $\frac{14}{22}$. E, $\frac{14}{22}$. H, $\frac{14}{22}$. F

And if in place of the first number a unit is taken, which is a part of some number, of which another number is the other part: then, conversely, the unit will be the same part of the third number that the second number is of the fourth. This is confirmed by the same argument, if in place of the parts we assume a part in the demonstration, as is clear from this example:

A. B. G. C D..... E..... H..... F

THEOR. 8. PROPOS. 10. [Margin: x.]

If a number is the same parts of a number, and another the same parts of another; then, conversely, whatever parts or part the first is of the third, the second also will be the same parts or part of the fourth.

Demonstration. Let the number AB be the same parts of the number C that the number DE is of the number F, and let AB, C be smaller than DE, F, each than each — for this proposition too is to be understood of these, just as the preceding one. I say that, conversely, the number AB is the same parts, or the same part, of the number DE that the number C is of the number F. For when the numbers AB, DE are divided into the parts AG, GB and DH, HE, equal to the numbers C and F, the multitude of the parts in AB will be equal to the multitude of the parts in DE, and each of AG and GB will be the same part of C that each of DH and HE is of F. [Margin: a — Elements VII.9] Conversely, therefore, AG will be the same part, or the same parts, of DH that GB is of HE. [Margin: b — Elements VII.5 or 6]

Therefore both AG, GB together, namely the whole AB, will be the same part or parts of both DH, HE together, namely DE, the third; that is, the same that C, the second, is of F, the fourth. Therefore, if a number is the same parts of a number, and the other the same parts of the other, and so on. Which was to be demonstrated.

A... G... B C..... D..... H..... E F..... [Margin: a — Elements VII.9;
b — Elements VII.5 or 6]

SCHOLIUM

The demonstration of this proposition is suited to fractional numbers as well, as appears in this example:

A, $\frac{2}{15}$. G, $\frac{2}{15}$. B C, $\frac{6}{15}$. D, $\frac{3}{10}$. H, $\frac{3}{10}$. E F, $\frac{9}{10}$.

THEOR. 9. PROPOS. 11. [Margin: xii. — see note (a)]

If the whole is to the whole as the subtracted is to the subtracted, then the remainder will be to the remainder as the whole is to the whole.

Demonstration. Let the whole number AB be to the whole CD as the subtracted AE is to the subtracted CF. I say that the remainder EB is to the remainder FD as the whole AB is to the whole CD. For since AB is to CD as AE is to CF, [Margin: a — Elements VII, def. 20] AB will be the same multiple of CD that AE is of CF, or the same part, or the same parts; or else AB will measure CD, and AE will measure CF, an equal number of times, and moreover will contain the same part or the same parts of it in addition.

Let AB first be a multiple of CD. On this supposition, conversely, CD will be the same part of the whole AB that the subtracted CF is of the subtracted AE, on account of AB, AE being equal multiples of CD, CF. [Margin: b — Elements VII.7] Therefore the remainder FD also is the same part of the remainder EB that the whole CD is of the whole AB; and accordingly, conversely, AB is to CD as EB is to FD, an equal multiple. [Margin: c — Elements VII, def. 20] Therefore the whole AB is to the whole CD as EB, the remainder, is to the remainder FD.

A..... E..... B C..... F... D [Margin: a — Elements VII, def. 20]

[p. 321]

Next, let AB be the same part, or the same parts, of CD that AE is of CF. On this supposition [Margin: d — Elements VII.7 or 8] the remainder EB also will be the same part, or the same parts, of the remainder FD that the whole AB is of the whole CD. And accordingly, it will be that as the whole AB is to the whole CD, so is EB, the remainder, to the remainder FD. [Margin: c — Elements VII, def. 20]

A..... E... B | A.... E.. B C..... F... D | C..... F... D [Margin: d — Elements VII.7 or 8; c — Elements VII, def. 20]

Finally, let AB contain CD a third time, and AE contain CF an equal number of times, and moreover the same part or the same parts of it. On this supposition, conversely, CD will contain the whole AB the same number of times, and the same parts, that the subtracted CF contains the subtracted AE — as we shall show presently. [Margin: f — Elements VII.8] Therefore the remainder FD also will be the same parts of the remainder EB that the whole CD is of the whole AB; and accordingly, conversely, AB will contain CD, and EB will contain FD, an equal number of times, together with the same part or parts of it in addition. [Margin: g — Elements VII.8]

A..... E..... B C..... F..... D

Therefore FD, the remainder, will be the same parts of the remainder EB that the whole CD is of the whole AB; and accordingly, it will be that as the whole AB is to the whole CD, so is EB, the remainder, to the remainder FD.

And if AB is equal to the whole CD, and the subtracted AE to the subtracted CF, it is evident that the remainder EB is equal to the remainder FD.

A..... E... B | C..... F... D

For if from equals equals are taken away, the remainders are equal. And so, if it is that as the whole is to the whole, so the subtracted is to the subtracted, and so on. Which was to be demonstrated.

SCHOLIUM

This is demonstrated in the same way in fractional numbers. This is plainly established in these examples, which correspond to the examples of the third case of the demonstration:

A, $\frac{6}{8}$. E, $\frac{1}{10}$ [?]. B | A, $\frac{14}{21}$ [?]. E, $\frac{28}{29}$ [?]. B C, $\frac{4}{9}$. F, $\frac{2}{10}$ [?]. C | C, $\frac{7}{21}$ [?]. F, $\frac{10}{29}$ [?]. D

LEMMA

But that, if AB contains CD, and AE contains CF, an equal number of times, together with the same part or parts of it in addition, then conversely CD is the same parts of AB, and CF the same parts of AE; and that, if CD is the same parts of AB, and CF the same parts of AE, then conversely AB contains CD, and AE contains CF, an equal number of times, together with the same part or parts of it in addition — this, both in fractional numbers and in whole numbers, we shall demonstrate as follows.

Let AB first contain CD, and AE contain CF, an equal number of times — namely once, or twice, or three times, and so on — and moreover the same part in addition, namely GB of CD, and HE of CF; so that the remaining numbers AG, AH are either equal to CD, CF themselves, or equal multiples of them. So when the numbers CD, CF are divided into the parts CI, IK, KD and CL, LM, MF equal to GB, HE, the multitude of the parts of the number CD will be equal to the multitude of the parts of the number CF (because GB is the same part of CD that HE is of CF). Similarly, when the numbers AG, AH are divided into the parts AN, NO, OG and AP, PQ, QH equal to the same GB, HE, the multitude of the parts of the number AG will also be equal to the multitude of the parts of the number AH.

A.. N.. O.. G.. B C.. I.. K.. D A.. P.. Q.. H.. E C.. L.. M.. F

For since AG, AH are either equal to CD, CF themselves, or equal multiples of them, there will be either just as many parts in AG, AH as in CD, CF; or else the number of the parts of the number CD will be contained in AG as many times as the number of the parts of the number CF is contained in AH; and on that account the multitude of the parts of the number AG will be equal to the multitude of the parts of the number AH. If, therefore, the parts GB, HE are added to these, the multitude of the parts of the number AB will also be equal to the multitude of the parts of the number AE. And so one part of the number CD is the same part of the number AB that one part of the number CF is of the number AE. Therefore, since the multitude of the parts of the number CD is equal to the multitude of the parts of the number CF, CD will be the same parts of the number AB that CF is of the same AE.

Next, let AB contain CD, and AE contain CF, an equal number of times — namely once, twice, three times, four times, and so on — and moreover the same parts of it in addition: the number AB the parts GB of the number CD, and the number AE the parts HE of the number CF; so that the remaining numbers AG, AH are, again, either equal to CD, CF themselves, or equal multiples of them. So when the numbers GB, HE are divided into the parts GI, IB and HK, KE, of the numbers CD, CF, the multitude of the parts of GB will be equal to the multitude of the parts of HE. In like manner, when the numbers CD, CF are divided into the parts CL, LM, MD and CN, NO, OF, equal to the parts GI, IB and HK, KE, [it will follow that these multitudes too are equal,] because each of the parts of the number GB is the same part of the number CD that each of the parts of the number HE is of the number CF. Finally, when the numbers AG, AH are divided into the parts AP, PQ, QG and AR, RS, SH, equal to the same parts GI, IB and HK, KE, the multitude of the parts of the number AG will also be equal to the multitude of the parts of the number AH.

A.. P.. Q.. G.. I.. B C.. L.. M.. D A.. R.. S.. H.. K.. E C.. N.. O.. F

For since AG, AH are either equal to CD, CF themselves, or equal multiples of them, there will be either just as many parts in AG, AH as in CD, CF; or else the number of the parts of the number CD will be contained in AG as many times as the number of the parts of the number CF is contained in AH; and on that account the multitude of the parts of the number AG will be equal to the multitude of the parts of the number AH. If to these are added the equal multitudes of the parts of the numbers GB, HE, there will also be a multi-[tude]

(Continuation of the LEMMA begun in the previous section — the second case, on the equivalence of "parts" with "containing an equal number of times, plus a part or parts," in whole and fractional numbers.)

[multi]tude of the parts of the number AB is equal to the multitude of the parts of the number AE. And thus one part of the number CD is the same part of the number AB as one part of the number CF is of the number AE. Therefore, since the multitude of the parts of the number CD is equal to the multitude of the parts of the number CF, CD will be the same parts of the number AB as CF is of AE. Which was the first thing proposed.

Now let CD be the same parts of AB, and CF the same parts of AE. I say, conversely, that AB contains CD, and AE contains CF, an equal number of times, and moreover the same part or parts of it. For when the numbers CD, CF are divided into parts equal to the numbers AB, AE, these parts will be equal to one another in multitude. Likewise, when the numbers AB, AE are divided into parts equal to the parts of the numbers CD, CF, these too will be equal to one another in multitude. Therefore all the parts of the number CD will be contained just as many times in AB — with the same part or parts of CD left over — as all the parts of the number CF are contained in AE, with whatever part or parts of CF remaining, because of the equal multitudes of the parts of the numbers CD, CF and AB, AE. For it so happens that the equal multitudes of the parts of the numbers AB, AE contain an equal number of times the equal multitudes of the parts of the numbers CD, CF, and moreover that in those two numbers there remain over parts of the numbers CD, CF equal in multitude. For this reason AB will contain CD, and AE will contain CF, an equal number of times, and moreover the same part or parts of it. Which was the second thing proposed.

[Margin: xiiij.]

THEOR. 10. PROPOS. 12.

If there be any number of proportional numbers, then as one of the antecedents is to one of the consequents, so are all the antecedents to all the consequents.

Let there be any number of proportional numbers A, B; C, D; E, F — that is, as A is to B, so C is to D, and E to F. I say that all of A, C, E together are also to all of B, D, F together as A is to B.

First let A, C, E be less than B, D, F. Since, then, by the same proportion, A is the same part (or parts) of B as C is of D and E is of F [Margin: a — Elem. VII.def.20], both A and C together will also be the same part (or parts) of both B and D together as A is of B, or as E is of F [Margin: b — Elem. VII.9 or 10]. Again, since both A and C together, taken as one, are the same part (or parts) of both B and D together, taken as one, as E is of F [Margin: c — Elem. VII.5], both A and C taken as one, together with E, will be the same part (or parts) of B and D taken as one, together with F, as A is of B [Margin: d — Elem. VII.def.20]. Therefore the ratio of all A, C, E together to all B, D, F together is the same as that of A to B.

Number-segment figure (first case — A, C, E less than B, D, F):

A.... C.. E...
B..... D.... F.....

Next let A, C, E be greater than B, D, F, and equal multiples of them. On this supposition, conversely B will be the same part of A as D is of C and F is of E; and so, as before [Margin: e — Elem. VII.5], all B, D, F together will be the same part of all A, C, E together as B is of A; and therefore, conversely, all A, C, E together are an equal multiple of all B, D, F together as A is of B [Margin: f — Elem. VII.def.20]. Hence the ratio of all A, C, E together to all B, D, F together is the same as that of A to B. This same thing holds even if some of the ratios — or indeed all of them — are ratios of numbers to a unit; for the demonstration is always the same, as appears here, with the help, however, of the scholium to proposition 5 of this book.

Number-segment figure (second case — A, C, E greater, and equal multiples):

A..... C.... E.....
B.... D.. F...

Paired number-segment figure (the two configurations of the foregoing conclusion):

A... C..... E..... | A... C... E...
 B. D.. F.... | B. D. F.

Third, let A, C, E be greater than B, D, F, but not multiples of them [Margin: g — Elem. VII.def.20]. Since, then, by the same proportion, A contains B, and C contains D, and E contains F an equal number of times, and moreover the same part or parts, then by the lemma before the preceding proposition [Margin: h — Elem. VII.6] B, D, F together will be the same parts of A, C, E together as B is of A; and so, as before, conversely A, C, E together will contain B, D, F together — and A will contain B — an equal number of times, and moreover the same part or parts [Margin: i — Elem. VII.def.20]. Therefore the ratio of all A, C, E together to all B, D, F together is the same as that of A to B.

Number-segment figure (third case — A, C, E greater, not multiples):

A..... C.... E.....
 B..... D... F.....

Fourth and last, let A, C, E be equal to B, D, F. Since, if to the equals A and B the equals C and D are added, A and C together become equal to B and D together; and if to these in turn the equals E and F are added, all A, C, E together become equal to all B, D, F together — they will be, as A is to B, so all A, C, E together to all B, D, F together, since in both cases the ratio is one of equality. Therefore, if there be any number of proportional numbers, then &c. Which was to be demonstrated.

Number-segment figure (fourth case — A, C, E equal to B, D, F):

A.... C... E....
 B... D... F....

SCHOLIVM.

In fractional numbers too this proposition will be proved true in the same way, as is plain, if fractions be assumed in place of whole numbers.

[Margin: xiv.]

THEOR. 11. PROPOS. 13.

If four numbers be proportional, they will also be proportional alternately.

For let A be to B as C to D. I say that, alternately, A is to C as B to D. First let A and C be less than B and D, and A also less than C. On this supposition, by the same

proportion, A will be the same part (or parts) of B as C is of D [Margin: a — Elem. VII.9 or 10]. Alternately, then, A will also be the same part (or parts) of C as B is of D [Margin: b — Elem. VII.def.20].

Next let A and C be less than B and D, but A greater than C. On this supposition, by the same proportion, C will be the same part (or parts) of D as A is of B. Alternately, then, C will be the same part (or parts) of A as D is of B [Margin: c — Elem. VII.9 or 10]; and so, conversely, either A will be an equal multiple of C as B is of D, or else — by the lemma to proposition 11 of this book — A will contain C, and B will contain D, an equal number of times, and moreover the same part or parts [Margin: d — Elem. VII.def.20]. Therefore, as A is to C, so B to D.

Number-segment figure (second case):

B..... D....
A..... C...

Third, let A and C be greater than B and D, but A less than C. On this supposition, by the same proportion, either A is an equal multiple of B as C of D, or else A contains B, and C contains D, an equal number of times, and moreover the same part or parts. And so, conversely, B will be either the same part of A (and D of C), or else — by the lemma to proposition 11 of this book — the same parts [Margin: e — Elem. VII.9 or 10]. Alternately, then, B will be the same part (or parts) of D as A is of C [Margin: f — Elem. VII.def.20]. And hence the ratio of B to D is the same as that of A to C — that is, as A is to C, so B to D.

Number-segment figure (third case):

A.... C.....
B... D.....

Fourth, let A and C be greater than B and D, and A also greater than C. On this supposition, by the same proportion, C will be either an equal multiple of D as A of B, or else C will contain D, and A will contain B, an equal number of times, and moreover the same part or parts. And so, conversely, D will be either the same part of C (and B of A), or else — by the lemma to proposition 11 of this book — the same parts [Margin: g — Elem. VII.9 or 10]. Alternately, then, D will be the same part (or parts) of B as C of A; and for that reason, conversely, either B will be an equal multiple of D as A of C, or else — by the lemma to proposition 11 of this book — B will contain D, and A will contain C, an equal number of times, and moreover the same part or parts [Margin: h — Elem. VII.def.20]. Therefore the ratio of B to D is the same as that of A to C — that is, as A is to C, so B to D.

Number-segment figure (fourth case):

A..... C....
B..... D...

Fifth, let A and C be equal to B and D, and A less than C. The equal numbers A and B are either the same part, or the same parts, of the equal numbers C and D [Margin: i — Elem. VII.def.20]. Therefore, as A is to C, so B to D.

Number-segment figure (fifth case):

A... C....
B... D....

Sixth, let A and C be equal to B and D, but A greater than C. Since, then, the equal numbers A and E [recte: B] are either equal multiples of the equal numbers C and D, or else those contain these an equal number of times, and moreover the same part or parts [Margin: k — Elem. VII.def.20], it will be, as A is to C, so B to D.

Number-segment figure (sixth case):

A..... C...
B..... D...

Seventh and last, let A and C be equal to one another — whether they be greater than B and D, or less, or equal. Since, then, by the same proportion, A is an equal multiple of B as C of D, or the same part, or the same parts; or else A contains B, and C contains D, an equal number of times, and moreover the same part or parts; and since A and C are equal, B and D will also be equal [Margin: l — Elem. VII.def.20]. And so it will be, as A is to its equal C, so B to its equal D. Wherefore, if four numbers be proportional, they will also be proportional alternately. Which was to be demonstrated.

Number-segment figure (seventh case):

A..... C.....
B... D...

SCHOLIVM.

If you substitute fractional numbers for whole numbers, you will prove in the same way that this proposition is true in fractional numbers.

It is also evident that this proposition does not vary even if one of the numbers be taken as a unit.

We have indeed been compelled, in this proposition and the two preceding ones, to review so many cases and to confirm them by the most certain demonstrations, together with the lemma to proposition 11, so that their truth might appear in every kind of rational ratio. For Theon [Theon of Alexandria] and some other commentators demonstrate them only for rational ratios of lesser inequality — those, namely, in which the antecedent numbers are parts of the consequents — as is plainly clear from the demonstrations of these same authors; unless we should say that a greater number is "parts" of a lesser number, as some concede — among whom is even (to my astonishment) Federico Commandino [Federico Commandino], an outstanding geometer — which is absurd, and foreign to Euclid's practice, since he would then have called a number "parts" of a number, a lesser of a greater, whereas the lesser does not measure the greater. This is also established, clearer than sunlight, from Definition 20, where he taught that numbers are proportional when the first is the same multiple, or the same part, or the same parts, of the second as the third is of the fourth, and so on. For if he had thought a greater number to be "parts" of a lesser, it would have been enough to say "when the first is the same part, or the same parts, of the second as the third is of the fourth." For thus he would have comprehended proportional numbers in every kind of ratio, as is manifest; so that all the remaining words of the definition would be superfluous.

[Margin: xv.]

THEOR. 12. PROPOS. 14.

If there be any number of numbers, and others equal to them in multitude, taken two and two in the same ratio, they will also be in the same ratio *ex aequali*.

Let there be any number of numbers A, B, C, and as many others D, E, F, such that as A is to B, so D to E, and as B is to C, so E to F. I say that *ex aequali* also, as A is to C, so D to F. For since as A is to B, so D to E, alternately A will be to D as B to E [Margin: a — Elem. VII.13]. And similarly, for the same reason, since as B is to C, so E to F, alternately B will be to E as C to F. Therefore, as A is to D, so C to F. (For since each ratio — A to D and C to F — is the same as the ratio B to E, as has been demonstrated, they will also be the same as one another, as will presently be shown.) [Margin: b — Elem. VII.13] And hence, alternately, as A is to C, so D to F.

But if there be more numbers than three, so that also as C is to G, so F to H, I say that still, as A is to G, so D to H. For since it has now been shown, for three numbers, that as A is to C, so D to F, and it is supposed that as C is to G, so F to H,

there will be three numbers A, C, G and three others D, F, H, taken two and two in the same ratio. Therefore, by what was shown *ex aequali* for three numbers, it will again be that as A is to G, so D to H. And in the same way we shall show the same for five numbers by means of four, just as it was demonstrated for four numbers by means of three; and so on for more. Therefore, if there be any number of numbers, and others equal to them in multitude, &c. Which was to be demonstrated.

Number-segment figure (Prop. 14):

A..... D.....
 B..... E.....
 C.... F...
 G..... H.....

SCHOLIVM.

It is evident, moreover, that this proposition can be demonstrated in the same way for fractional numbers, if fractions be assumed in place of whole numbers.

Number-segment figure (fractional example):

A. D...
 B.. E.....
 C... F.....
 G. G...

The same is true if in place of a single number a unit be taken, or even, in place of several numbers, several units, as is clear in this example.

LEMMA.

That two ratios of numbers which are the same as the same ratio are also the same as one another — such as, in the demonstration, are the ratios A to D and C to F, which were shown to be the same as the ratio B to E — whether the numbers be whole or fractional, will be demonstrated thus. By the same proportion,

Number-segment figure (Lemma):

A..... B..... C....
 D..... E..... F...

B will be an equal multiple of E, and both A of D and C of F, or the same part, or the same parts; or else B will contain E — and both A will contain D and C will contain F — an equal number of times, and moreover the same part or parts

[Margin: c — Elem. VII.def.20]. Therefore the numbers A, D, C, F are proportional, namely, as A is to D, so C to F. Which was proposed.

This same thing was demonstrated by Euclid in Book 5, on the proportions of magnitudes, proposition 11 (*Elements* V.11).

[Margin: xvi.]

THEOR. 13. PROPOS. 15.

If a unit measure some number as many times as another number measures another number, then alternately the unit too will measure the third number equally many times, and the second the fourth.

Let the unit A measure the number BC as many times as the number D measures the number EF. I say that, alternately, the unit A measures the number D, and the number BC measures the number EF, equally many times. For when the number BC is divided into the units BG, GH, HC, and the number EF into the parts EI, IK, KF equal to D, the multitude of the units of the number BC will be equal to the multitude of the parts of the number EF; and the unit A will measure the number D as often as the unit BG measures EI, the unit GH measures IK, and the unit HC measures KF; and therefore the unit A is the same part of the number D as the unit BG is of the number EI, as the unit GH is of the number IK, and as the unit HC is of the number KF. Wherefore, by what we showed at proposition 5 of this book, the units BG, GH, HC together will be the same part as the unit BG is of the number EI — that is, as the unit A is of the number D. And hence the unit A will measure the number D, and the number BC (composed of the units BG, GH, HC) will measure the number EF (composed of the numbers EI, IK, KF), equally many times. If, therefore, a unit measure some number, &c. Which was to be demonstrated.

Number-segment figure (Prop. 15):

A. D. .
B. G. H. C. E. . I. . K. . F

SCHOLIVM.

That very thing which Euclid demonstrated concerning numbers at proposition 13, he here shows separately concerning the unit and three numbers, because the unit is not a number. This, indeed, we shall demonstrate more briefly thus. Since the unit A measures the number BC as often as the number D measures the number EF, the unit A will be the same part of the number BC as the number D is

of the number EF. Therefore, by what we demonstrated at proposition 9, alternately the unit A will be the same part of the number D as the number BC is of the number EF; and for that reason the unit A will measure the number D, and the number BC the number EF, equally many times.

This proposition cannot hold for fractional numbers. For if a unit measure some number, and another fractional number measure another fractional number equally many times, the unit will not, alternately, measure equally the third number (which is taken as fractional), nor the second the fourth fractional number [Margin: a — Elem. VII.13]; but the unit will only have the same ratio to the third number as the second has to the fourth.

[Margin: xvij.]

PROBL. 14. BROPOS. 16.

If two numbers, multiplying one another, make certain numbers, the products of them will be equal to one another.

Let two numbers A and B, multiplying one another, make the numbers C and D, such that A multiplying B makes C, and B multiplying A makes D. I say that the numbers C and D are equal to one another. For, taking the unit E: since A multiplying B makes C [Margin: a — Elem. VII.def.15], C will be composed of B as many times as there are units in A; and so the unit E will measure the number A, and the number B will measure the number C, equally many times [Margin: b — Elem. VII.15]. Alternately, then, the unit E will measure the number B, and the number A will measure the number C, equally. Again, in the same way, since B multiplying A makes D [Margin: c — Elem. VII.def.15], D will be composed of A as many times as there are units in B; and so the unit E will measure the number B, and the same number A will measure the number D, equally. But the same unit E was also measuring the same number B, and the same number A was measuring C, equally. Therefore the number A measures both numbers C and D equally; and hence C and D will be equal to one another. If, therefore, two numbers, multiplying one another, make certain numbers, &c. Which was to be demonstrated.

Number-segment figure (Prop. 16):

E.
A... B....
D..... C.....

SCHOLIUM

In fractional numbers this proposition must be demonstrated as follows. Since A, multiplying B, makes C, then by the definition of multiplication C will be to B as A is to E, the unit. Therefore, alternately, C is to A as B is to E, the unit. But by the same definition, as B is to E, the unit, so too is D to A — D being what B produces by multiplying A. Consequently, by the lemma of proposition 14, C is to A as D is to that same A; and therefore C and D are equal to one another. Which was to be demonstrated.

E.

A, $\frac{2}{3}$. B, $4\frac{5}{7}$.

D, $3\frac{1}{7}$. C, $3\frac{1}{7}$.

This same proposition can also be stated, with Campanus [Campanus], in the following way:

If two numbers multiply one another, one and the same number will be produced.

For let A multiply B and make C. I say that the same C is generated if B multiplies A. As before, when A multiplying B makes C, we shall show that the unit E measures the number B, and that the number A measures the number C, in the same way. And likewise, if the number B multiplies A, the unit E also measures the number B, and the number A measures the number produced, in the same way. Therefore the same number C is generated from the multiplication of B into A, since it too measures the number A just as the unit E measures B.

E.

A... B....

C.....

[Margin: a — Def. VII.15]

But if the numbers A and E are both fractional, or one of them is, we shall demonstrate the same in this way. Since A, multiplying B, makes C, then by definition 15, C is to B as A is to E, the unit. And alternately, C is to A as B is to E, the unit. But if B multiplies A, then by the same definition 15, B is to E, the unit, as the produced number is to A. Therefore C is to A as this produced number is to the same A; and consequently this produced number will be the same as C. Which is what was proposed.

THEOR. 15. PROPOS. 17.

[Margin: xvii.]

If a number, multiplying two numbers, produces certain products, the numbers generated from them will have the same ratio as the numbers multiplied.

For let the number A, multiplying the numbers B and C, make D and E. I say that D is to E as B is to C. Take the unit F. Then D is composed [Margin: a — Def. VII.15] out of B as many times as the unit F is contained in A; and likewise E is composed out of C as many times as that same unit F is contained in the same A. And therefore B measures D, and C measures E, in the same way. Hence B is the same part of D that C is of E. Consequently B is to D as C is to E [Margin: b — Def. VII.20]; and, alternately, B is to C as D is to E [Margin: c — VII.13]. So if a number, multiplying two numbers, produces certain products, and so on. Which was to be shown.

F.
A...
B.. C....
D..... E.....

SCHOLIUM

If the numbers A, B, C are fractional — one of them, or two — we shall show the same in this way. Since A, multiplying B and C, makes D and E, then by definition 15 both D is to B and E is to C as A is to F, the unit; and consequently, by the lemma of proposition 14, D is to B as E is to C. Therefore, alternately, D is to E as B is to C. Which is what was proposed.

THEOR. 16. PROPOS. 18.

[Margin: xix.]

If two numbers, multiplying some number, produce certain products, the numbers generated from them will have the same ratio as the multipliers.

For let the numbers A and B, multiplying the number C, make D and E. I say that A is to B as D is to E. For since D arises from A into C, the same D will also arise [Margin: a — VII.16] from C into A. And by the same reasoning, since E arises from B into C, the same E will arise from C into B. Since, then, the same C, multiplying A and B, makes D and E, it follows that A is to B as D is to E [Margin: b

— VII.17]. So if two numbers, multiplying some number, produce certain products, and so on. Which was to be demonstrated.

A.... B.....

C...

D..... E.....

SCHOLIUM

It is perfectly clear that this same proposition is demonstrated in the same way if the numbers A, B, C are fractional — one of them, or two.

Both this proposition and the preceding one we shall extend, with Campanus [Campanus], to any number of numbers, whether the numbers are all whole or not, by the following reasoning:

If one number multiplies any number of numbers, or any number of numbers multiply some one number, the products will have the same ratios as the numbers multiplied or the multipliers.

For let E, F, G arise from A into B, C, D, or from B, C, D into A. I say that the products E, F, G have the same ratios that the multiplying — or multiplied — numbers B, C, D have: that is, that B is to C as E is to F, and C is to D as F is to G. For since EF arise from A into BC, or from BC into A, B will be to C as E is to F [Margin: a — VII.17 or 18]. Likewise, because F, G arise from A into C, D, or from C, D into A, C will be to D as F is to G. And so for the rest.

A...

B.. C... D....

E..... F..... G.....

THEOR. 17. PROPOS. 19.

[Margin: xix.]

If four numbers are proportional, the number produced from the first and fourth will be equal to the one produced from the second and fourth [recte: third]. And if the number produced from the first and fourth is equal to the one produced from the second and third, the four numbers will be proportional.

Let there be four proportional numbers A, B, C, D, such that A is to B as C is to D; and let E arise from A, the first, into D, the fourth, and F from B, the second, into C, the third. I say that the numbers E and F are equal to one another. Let G in turn arise from A into C. Then, since G, E arise from A into C, D, C will be to D — that is,

A to B — as G is to E [Margin: a — VII.17]. Again, since G, F arise from A and B into C, it will likewise hold that A is to B as G is to F [Margin: b — VII.18]. Therefore, by the lemma of proposition 14, G has the same proportion to both E and F — namely the one that A has to B; and consequently the numbers E and F are equal, by what we wrote at definition 20.

Now let E, generated from A, the first, into D, the fourth, be equal to F, produced from B, the second, into C, the third. I say that the four numbers A, B, C, D are proportional, so that A is to B as C is to D. Let G again arise from A into C. Since, then, G, E arise from A into C, D, C will be to D as G is to E [Margin: c — VII.17], or as it is to F, which equals E — for G has the same ratio to the equal numbers E, F, as we taught at definition 20. Again, since G, F arise from A and B into C, it will likewise hold that A is to B as the same G is to the same F [Margin: d — VII.18]. Therefore the proportions of A to B and of C to D, since they are the same as the proportion of G to F, are the same as one another, by the lemma of proposition 14. And consequently A is to B as C is to D. So if four numbers are proportional, and so on. Which was to be shown.

A...
 B..
 C.....
 D....
 E.....
 F.....
 G.....

SCHOLIUM

It is clearer than daylight that the same demonstration of this proposition holds in fractional numbers, whether they are all fractional or not.

The first part of this theorem could also be stated in the following manner, in fractional numbers as well as in whole ones:

If two numbers multiply two numbers having the same ratio as they do — the antecedent of the former multiplying the consequent of the latter, and the consequent the antecedent — the products will be equal to one another.

For it has been shown in just this way that the number E, which arises from A, the antecedent, into D, the consequent, is equal to the number F, which is produced from B, the consequent, into C, the antecedent.

Moreover, the following theorem, in fractional numbers as well as in whole ones, will easily be demonstrated from this proposition 16.

If the ratio of the first to the second is greater than that of the third to the fourth, the number produced from the first and fourth will be greater than the one produced from the second and third. And if the number produced from the first and fourth is greater than the one produced from the second and third, the ratio of the first to the second will be greater than that of the third to the fourth.

First, let the ratio of A, the first, to B, the second, be greater than that of C, the third, to D, the fourth. I say that the number produced from A into D is greater than the one produced from B into C. For suppose E to be to B as C is to D — whether E be a whole number, or fractional, or a whole with a fraction; and such an E will be found, as we shall show at proposition 19 of book 9, if the number produced from B into C is divided by D. Then the ratio of A to B will also be greater than that of E to B; and consequently A is greater than E. Hence a greater number will arise from A into D than from E into the same D. But the number arising from E into D is equal to the one arising from B into C [Margin: a — VII.19]. Therefore the number generated from A into D will be greater than the number produced from B into C. Which is what was proposed.

A..... E.....
B....
C.....,
D.....

Next, let a greater number arise from A into D than from B into C. I say that the ratio of A, the first, to B, the second, is greater than that of C, the third, to D, the fourth. For if the number E is understood to be such that from it into D the same number arises as from B into C — whether E be a whole number, or fractional, or a whole with a fraction — a greater number will also arise from A into D than from E into the same D; and consequently the ratio of A to B will be greater than that of E to B [Margin: b — VII.19]. But E is to B as C is to D. Therefore the ratio of A to B will also be greater than that of C to D. Which is what was proposed.

But if the ratio of the first to the second is less than that of the third to the fourth, the number produced from the first and fourth will be less than the one produced from the second and third; and if the number produced from the first and fourth is less than the one produced from the second and third, the ratio of the first to the second will be less than that of the third to the fourth. For the demonstration will be exactly the same, provided you change the word "greater" into the word

"less," as appears in this appended example. Nevertheless, it can also be shown in this way. Since the ratio of A to B is less than that of C to D — that is, the ratio of C, the first, to D, the second, is greater than that of A, the third, to B, the fourth — a greater number will arise from C, the first, into B, the fourth, or from B into C, than from D, the second, into A, the third, or from A into D, as has already been demonstrated: that is, a smaller number will arise from A into D, or from D into A; which is what was proposed. Then, if a smaller number arises from A into D than from B into C — that is, a greater one from B into C, or from C into B, than from A into D, or from D into A — the ratio of C, the first, to D, the second, will be greater than that of A, the third, to B, the fourth, as has already been demonstrated: that is, the ratio of A to B will be less than that of C to D. Which is what was proposed.

A..... E.....
 B....
 C...
 D..

THEOR. 18. PROPOS. 20.

[Margin: xx.]

If three numbers are proportional, the number contained by the extremes is equal to the one produced from the mean; and if the number contained by the extremes is equal to the one described from the mean, the three numbers will be proportional.

Let there be three proportional numbers A, B, C, such that A is to B as B is to C. I say that the number arising from A, the first, into C, the third, is equal to the one produced from B, the mean. For take D equal to B: then B will be to C — that is, A to B — as D is to C; and the number generated from B into D will be equal to the one produced from B into itself. Since, then, the four numbers A, B, D, C are proportional, the number made from A into C will be equal [Margin: a — VII.19] to the one arising from B into D — that is, to the one produced from B into itself.

Now let the number produced from A, the first, into C, the third, be equal to the one arising from B, the mean, into C. I say that the three numbers A, B, C are proportional. For take D again equal to B: then B will be to C as D is to C, and the number arising from B into D will be equal to the one arising from B into itself — that is, to the one arising from A into C. Since, then, the number arising from A, the first, into C, the fourth, is equal to the one arising from B, the second, into D, the third, the four numbers A, B, C, D will be proportional [Margin: b — VII.16], so

that A is to B as D is to C, or as B is to C. So if three numbers are proportional, and so on. Which was to be demonstrated.

A.....
 B..... D.....
 C.....

SCHOLIUM

This demonstration will not vary even if the numbers A, B, C are fractional, or partly whole and partly fractional.

But if the ratio of the first to the second is greater than that of the second to the third, a greater number will arise from the first into the third than from the second into itself; and if a greater number arises from the first into the third than from the second into itself, the ratio of the first to the second will be greater than that of the second to the third. Likewise, if the ratio of the first to the second is less than that of the second to the third, a smaller number will arise from the first into the third than from the second into itself; and if a smaller number arises from the first into the third than from the second into itself, the ratio of the first to the second will be less than that of the second to the third. This is clear from the scholium of the preceding proposition, if another number equal to the second is taken, so that four numbers are had. For then the ratio of the first to the second will be greater than that of the third to the fourth, or less, and so on — as appears in the appended examples, even if the numbers are fractional, or partly fractional and partly whole.

A..... A....
 B..... D..... B..... D
 C..... C.....

THEOR. 19. PROPOS. 21.

[Margin: xxj.]

The least numbers among all those having the same ratio with them measure equally the numbers that have the same ratio with them — the greater indeed measuring the greater, the less the less.

Let AB, CD be the least numbers in the ratio in which two other, greater, numbers E, F stand, so that AB is to CD as E is to F. I say that AB, CD measure E, F equally — the greater, AB, measuring the greater, E, and the less, CD, the less, F: that is, the antecedent measuring the antecedent, and the consequent the consequent. For since AB is to CD as E is to F, it will hold, alternately, that AB is to E as CD is to F

[Margin: a — VII.13]. And so, since AB, CD are less than E, F, AB will be the same part, or the same parts, of E that CD is of F [Margin: b — Def. VII.20]. Now they are certainly not "parts": for if AB, CD could be divided into parts AG, GB and CH, HD of the numbers E, F, the number of parts AG, GB would be equal to the number of parts CH, HD; and therefore AG would be the same part of E that CH is of F. Then AG would be to E as CH is to F [Margin: c — Def. VII.20]; and, alternately, AG would be to CH as E is to F, or as AB is to CD [Margin: d — VII.13]. And consequently the numbers AG, CH, less than AB, CD, would have the same proportion as AB to CD. Which is absurd, since AB, CD are supposed to be the least in their proportion. So AB, CD are not the same parts of E, F; they are therefore the same part. And on that account AB will measure E, and CD measure F, equally. Therefore the least numbers among all those having the same ratio with them, and so on. Which was to be demonstrated.

A... G.. B

 F.....

SCHOLIUM

The same holds true if one says that three numbers are in continued proportion and that the first two are the least in their proportion. For, this being posited, it will be shown in the same way that the first measures the second, and the second the third — as appears in this appended example, where the third number is equal to the second. And although three numbers in continued proportion, of which the first two are the least in their proportion, cannot be given unless the first is a unit, the same is nevertheless demonstrated in three numbers, even if the first is not conceded by the opponent to be a unit, as we said. I have said this so that proposition 12 of book 9 may be demonstrated — in which the opponent is forced to concede that three numbers are in continued proportion, and that the first two are the least in their proportion, and consequently that the first measures the second, by this proposition, which he previously denied. But this will be made plainer at proposition 12 of book 9.

By like reasoning, that too is true which Campanus [Campanus] teaches.

A.. G.. B
 C... H... D
 E.....
 F.....

Any number of least numbers in the continuation of their ratios — whether the ratios are the same or different — measure equally as many other numbers that have the same ratios with them: the first measuring the first, the second the second, the third the third, and so on.

For let there be more than two numbers AB, CD, EF, the least in the continuation of their ratios — whether the ratio of AB to CD is the same as that of CD to EF, or not — such that no other numbers less than AB, CD, EF can be found whose first is to the second ...

A... K... B C... L. D E.... M.... F
G..... H..... I.....

Euclid, *Elements*, Book VII (Clavius's commentary) — continued

(Global = printed folios 328–330. Running headers: verso "EVCLID. GEOM.", recto "LIBER VII.")

[continuation of PROPOS. 21 — the least numbers in a continued series of ratios]

such that the first is to the second as AB is to CD, and the second to the third as CD to EF, and so on. (Such ratios may indeed be found separately in smaller numbers not standing in continued proportion: namely the ratio of AB to CD in the numbers 4 to 2, or 2 to 1, which are smaller than AB and CD themselves; just as the ratios of the numbers 16, 20, 25 — which are the least in the continuation of two sesquiquartan ratios [5:4], since they cannot be continued in smaller numbers — are found separately in smaller numbers: the ratio 16 to 20 indeed in 8 and 10, but the ratio 20 to 25 in 4 and 5, or in 12 and 15.)

Let there then be as many other numbers G, H, I, not the least, continued in the same ratios — namely G to H as AB to CD, and H to I as CD to EF. I say that AB measures G, CD measures H, and EF measures I, equally.

For since AB is to CD as G is to H, [Margin: a — VII.13] it will alternately be, as AB is to G, so CD to H. In the same way, since CD is to EF as H is to I, [Margin: b — VII.13] it will likewise be, alternately, as CD to H, so EF to I. [Margin: c — VII, Def. 20] Therefore AB will be either the same part, or the same parts, of G that CD is of H and EF is of I. But "the same parts" is impossible. For if AB, CD, EF be divided (were it possible) into AK, KB; CL, LD; EM, MF — parts of the numbers G, H, I —

there will be as many parts in AB as in CD and in EF, and thus AK will be the same part of G that CL is of H [Margin: d — VII, Def. 20] and EM of I. It will therefore be, as AK is to G, so CL to H [recte: ita CL, ad H]; [Margin: e — VII.13] and alternately, as AK is to CL, so G to H, or AB to CD. In the same way it will be as CL to FN [?] as CD to EF. Hence the numbers AK, CL, EM are continued in the ratios of the numbers AB, CD, EF, and are smaller than AB, CD, EF. This is absurd, since these last were assumed to be the least in the continuation of their ratios. Therefore AB, CD, EF are not the same parts of the numbers G, H, I. Hence each is the same single part of its own; and consequently AB will measure G, CD will measure H, and EF will measure I, equally. Which is what was proposed.

And if three given numbers A, B, C be the least in the continuation of their ratios, in such a way that also any two of them are the least, the same will be demonstrated still more easily in this manner. Let there be three others, D, E, F, not the least, having the same ratios as A, B, C. I say that A, B, C measure D, E, F equally. For, by this proposition 21, since A, B are the least in the ratio of A to B, they measure D, E equally; and by the same reasoning B, C measure E, F. Therefore, since A measures D and

D.... E..... F.....
A.. B..... C...

C measures F equally, and B measures E, all of A, B, C will measure D, E, F equally.

[Clavius's remark.] For the rest, this proposition, together with its scholium, can in no way apply to fractional numbers, because among fractions no least numbers can be given in a given ratio: whatever be given, still smaller ones can be given, and so on to infinity. And the same is to be understood in all the other propositions in which mention is made of least numbers, for they are all to be understood of whole numbers only. So too, whenever numbers prime to one another are treated, fractions must be excluded, since these cannot be prime to one another — any fraction whatever can measure them as a common measure. For if they be reduced to the same denomination, it is evident that they have as a common measure one small part, or several, of the same denomination. But all the other propositions about numbers, in which least numbers in their ratio, or numbers prime to one another, are not employed, apply equally to whole and to fractional numbers — which it is enough to have pointed out this once, here.

THEOR. 20. PROPOS. 22.

[Margin: xix.]

If there be three numbers, and others equal to them in multitude which are taken two and two and in the same ratio, but their proportion be perturbed, then ex aequali they too will be in the same ratio.

Let there be three numbers A, B, C, and as many others D, E, F, taken two and two and in the same ratio, and let their proportion be perturbed — namely as A is to B, so E to F; and as B is to C, so D to E. I say that ex aequali also it is, as A is to C, so D to F.

A..... H...
B... D....
C..... E.....
G..... F..

For since A is to B as E is to F, [Margin: a — VII.19] the number produced from A into F will be equal to the number that arises from B into E. By like reasoning, since also B is to C as D is to E, [Margin: b — VII.19] there will be, equal to the same number that arises from B into E, the number that arises from C into D. And thus the number produced from A, the first, into F, the fourth, will be equal to the number produced from C, the second, into D, the third. [Margin: c — VII.19] Therefore it will be, as A is to C, so D to F.

And if there be more numbers than three, in such a way that also C is to G as H is to D, I say that still it is, as A is to G, so H to F. For since it has now been shown, in the case of three numbers, that as A is to C, so D to F, and it is assumed that as C is to G, so H to D, there will be three numbers A, C, G and three others H, D, F, taken two and two in the same ratio, and their proportion is perturbed. By the ex aequali case already shown for three numbers, it will again be, as A is to G, so H to F. In the same way we shall show it for five numbers by means of four, just as it was demonstrated for four numbers by means of three; and so for more. Accordingly, if there be three numbers, and others equal to them in multitude taken two and two, and so on. Which was to be shown.

SCHOLIVM.

The proposition will be demonstrated in the same way for fractional numbers, as is evident.

Now since Euclid, out of those six modes of arguing in proportions which he set forth and confirmed by demonstrations for magnitudes in Book 5, has here exhibited for numbers only two — namely the one drawn from alternated proportion (permutando), in proposition 13, and the one called ex aequali, in propositions 14 and 22 of this book — it will not be foreign to our purpose to set

forth briefly the remaining four modes in numbers, and certain others among the following theorems of the fifth book, all of which apply to fractional numbers as well as to whole ones.

I.

If four numbers be proportional, they will also be proportional inversely, that is, by inverting.

Let it be, as A is to B, so C to D. I say that also, by inverting (that is, by inverse ratio), it is as B to A, so D to C.

A C . . .
B D . .

For since A is to B as C is to D, [Margin: a — VII.13] it will alternately be, A to C as B to D. Again, since B is to D as A is to C, [Margin: b — VII.13] it will alternately be, B to A as D to C. Which is what was proposed.

II.

If compounded numbers be proportional, these too, separated, will be proportional.

[LIBER VII. — printed folio 329]

Let it be, as AB is to CB, so DE to FE. I say that, by separation (dividendo), it is as AC to CB, so DF to FE. For since AB is to CB as DE is to FE, [Margin: a — VII.13] alternately the whole AB will be to the whole DE as the taken-away CB to the taken-away FE; [Margin: b — VII.11] and consequently, as the whole AB is to the whole DE, so the remainder AC to the remainder DF; that is, AC is to DF as CB is to FE. [Margin: c — VII.13] Alternately, therefore, it will also be AC to CB as DF to FE. Which is what was proposed.

A C . . . B
D F . . E

By the same reasoning we shall demonstrate the converse and the contrary of separation of ratio, as in Book 5. First, let it be as AB to CB, so DE to FE. I say that, by the converse of separation of ratio, it is also as CB to AC, so FE to DF. For since AB is to CB as DE is to EF, by separation it will also be as AC to CB, so DF to FE; and by conversion, as CB to AC, so FE to DF. Which is what was proposed.

Next, let it be as AC to AB, so DF to DE. I say that, by the contrary of separation of ratio, it is also as AC to CB, so DF to FE. For since AC is to AB as DF is to DE, by

conversion it will be as AB to AC, so DE to DF. Therefore by separation, as CB to AC, so FE to DF; and by conversion, as AC to CB, so DF to FE. Which is what was proposed.

III.

If separated numbers be proportional, these too, compounded, will be proportional.

Let it be, as AB is to BC, so DE to EF. I say that, by compounding (componendo), it is also as AC to BC, so DF to EF. For since AB is to BC as DE is to EF, [Margin: a — VII.13] it will alternately be as AB to DE, so BC to EF; [Margin: b — VII.12] and consequently AB, BC together are to DE, EF together as BC is to EF; [Margin: c — VII.13] and alternately AB, BC together — that is, the whole AC — is to BC as DE, EF together — that is, the whole DF — is to EF. Which is what was proposed.

A B . . . C
D E . . F

Likewise the converse and the contrary of compounding of ratio will be shown in this place, as in Book 5. First, let it be as AB to BC, so DE to EF. I say that, by the converse of compounding of ratio, it is also as AC to AB, so DF to DE. For since AB is to BC as DE is to EF, it will be by conversion as BC to AB, so EF to DE; and by compounding, as AC to AB, so DF to DE. Which is what was proposed.

Next, let it be again as AB to BC, so DE to EF. I say that, by the contrary of compounding of ratio, it is also as AB to AC, so DE to DF. For since AB is to BC as DE is to EF, it will be by conversion as BC to AB, so EF to DE. Therefore by compounding, as AC to AB, so DF to DE; and by conversion, as AB to AC, so DE to DF. Which is what was proposed.

IV.

If compounded numbers be proportional, these too will be proportional by conversion of ratio.

Let it be, as AB is to CB, so DE to FE. I say that, by conversion of ratio, it is also as AB to AC, so DE to DF. For since AB is to CB as DE is to FE, [Margin: a — VII.13] alternately the whole AB will be to the whole DE as the taken-away CB to the taken-away FE; [Margin: b — VII.11] and consequently, as the whole AB to the whole DE, so will the remainder AC be to the remainder DF. [Margin: c — VII.13] Alternately, therefore, as AB to AC, so DE to DF. Which is what was proposed.

A C . . . B
D F . . E

Again, from these we shall easily demonstrate in numbers that theorem which Euclid shows for magnitudes in proposition 24 of Book 5. Namely:

V.

If a first have to a second the same ratio as a third to a fourth, and a fifth also have to the second the same ratio as a sixth to the fourth, then the first compounded with the fifth will have to the second the same ratio as the third compounded with the sixth has to the fourth.

Let it be, as AB, the first, is to C, the second, so DE, the third, to F, the fourth; likewise as BG, the fifth, is to C, the second, so EH, the sixth, to F, the fourth. I say that AG, compounded of the first and fifth, is to C, the second, as DH, compounded of the third and sixth, is to F, the fourth.

A..... B.. G | D..... E... H
C.... F.....

For since BG is to C as EH is to F, it will be by conversion, as C to BG, so F to EH. Since, then, AB is to C as DE is to F, and C is to BG as F is to EH, it will be ex aequali as AB to BG, so DE to EH. By compounding, therefore, as AG to BG, so DH to EH. And so, since again AG is to BG as DH is to EH, and BG is to C as EH is to F, ex aequali it will be as AG to C, so DH to F. Which is what was proposed.

In the same way we shall show this theorem too, which we demonstrated for magnitudes in proposition 24 of Book 5.

VI.

If two numbers have to two numbers the same ratio, and certain subtracted numbers have to the same the same ratio, then the remainders too will have to the same the same ratio.

Let it be, as the whole AB is to C, so the whole DE to F; likewise as the subtracted AG is to C, so the subtracted DH to F. I say that the remainder GB too is to C as the remainder HE is to F. For since AG is to C as DH is to F, it will be by conversion as C to AG, so F to DH. Since, then, AB is to C as DE is to F, and C is to AG as F is to DH, it will be ex aequali as AB to AG, so DE to DH. By separation, therefore, as GB to AG, so HE to DH. And so, since again GB is to AG as HE is to DH, and AG is to C as DH is to F, ex aequali it will be as GB to C, so HE to F. Which is what was proposed.

A..... G., B D..... H... E
C.... F.....

This too we shall demonstrate.

VII.

[EVCLID. GEOM. — printed folio 330]

If a first have to a second the same ratio as a third to a fourth, and the first also have to a fifth the same ratio as the third to a sixth, then the first will have to the second and fifth compounded the same ratio as the third has to the fourth and sixth compounded.

Let the first, A, be to the second, BC, as the third, D, is to the fourth, EF; and let the first, A, be to the fifth, CG, as the third, D, is to the sixth, FH. I say that A, the first, is to BG (compounded of the second and fifth) as D, the third, is to EH (compounded of the fourth and sixth).

A..... D.....
B... C.. E..... F.... H

For since A is to BC as D is to EF, it will be by conversion as BC to A, so EF to D. Since, then, BC is to A as EF is to D, and A is to CG as D is to FH, it will be ex aequali as BC to CG, so EF to FH; and by compounding, as BG to CG, so EH to FH. Therefore, since A is to CG as D is to FH, [and] as CG is to BG, so FH [is to EH; ex aequali, as A is to BG, so D is to EH] [?]. Which is what was proposed. [recte: propositum; printed "rpropositum"]

And finally, from all these we shall infer this theorem.

VIII.

If any numbers whatever have to the same number the ratios that others equal to them in multitude have to some other same number, then all these together will also have to the same number the ratio that all those others together have to that other same number. And if the same number have to any numbers whatever the ratios that the same other number has to others equal to them in multitude, then the same number will also have to all of them together the ratio that the same other number has to all these together.

Let any numbers whatever AB, BC, CD have ratios to the same number K — that is, let it be as AB to E, so FG to K; and as BC to E, so GH to K; and as CD to E, so HI to K. I say that all of them together — that is, AD itself — has to E the same ratio that all these together have, that is, that FI itself has to K. For since it is, as AB, the first, is to E, the second, so FG, the third, to K, the fourth; likewise as BC, the fifth,

is to E, the second, so GH, the sixth, to K, [the fourth,] it will also be, as AC, the first with the fifth, is to E, the second, so FH, the third with the sixth, to K, the fourth.

A.... B..... C..... D | F. G... H.... I
E..... K.....

Again, since AC, the first, is to E, the second, as FH, the third, is to K, the fourth; likewise as CD, the fifth, is to E, the second, so HI, the sixth, to K, the fourth; it will also be, as AD, the first with the fifth, is to E, the second, so FI, the third with the sixth, to K, the fourth. And so of the rest, if there be more.

But now let the same number E have to any numbers whatever AB, BC, CD the same ratios that the same other number K has to as many others FG, GH, HI — that is, let it be as E to AB, so K to FG; and as E to BC, so K to GH; and as E to CD, so K to HI. I say that it is, as E to all of them together, namely to AD, so K to all of them together, namely to FI. For since it is, as E, the first, is to AB, the second, so K, the third, to FG, the fourth; likewise as E, the first, is to BC, the fifth, so K, the third, to GH, the sixth; it will also be, as E, the first, is to AC, the second with the fifth, so K, the third, to FH, the fourth with the sixth. Again, since it is, as E, the first, is to AC, the second, so K, the third, to FH, the fourth; likewise as E, the first, is to CD, the fifth, so K, the third, to HI, the sixth; it will also be, as E, the first, is to AD, the second with the fifth, so K, the third, to FI, the fourth with the sixth. And so of the rest, if there be more.

Now, these things being demonstrated, the nine last propositions of Book 5, added by Campanus, will be shown for disproportional numbers in the same way in which they were demonstrated for magnitudes: if, in place of magnitudes, numbers be understood, whether whole or fractional, and, in place of the modes of arguing in proportions demonstrated in Book 5, the same modes demonstrated in this book be assumed — so that there is no need to repeat them here. For it is enough, as I have said, that those propositions of the fifth book be taken in hand, and the magnitudes be understood to be numbers, and the very same demonstrations be applied.

THEOR. 21. PROPOS. 23.

[Margin: xxj.]

Numbers prime to one another are the least of all having the same ratio with them.

Let there be numbers A, B prime to one another. I say that they are the least of all that have the same ratio as A and B. For if they are not the least, there will be

certain others smaller than they, being the least, that have the ratio which A and B have. Let there be, then, if it be possible, C, D, the least in the ratio of A and B, and therefore smaller than A and B.

A..... B....
 C—— D—
 E——

Since, then, C, D are the least in the ratio of A and B, [Margin: a — VII.21] C will measure A, and D will measure B, equally; and thus according to the same number, which let be E, so that C measures A as many times, and D measures B, as there are units in E. Accordingly, since the unit measures the number E, and the number C measures the number A, equally, [Margin: b — VII.15] alternately too the unit will equally measure the number C, and the number E measure the number A. Again, since the unit measures the number E, and the number D measures the number B, equally, [Margin: c — VII.15] alternately too the unit will equally measure the number D, and the number E measure the number B. And thus, since the same number E measures both A and B, the number E will be their common measure. Therefore A and B are not prime to one another, but composite. This is absurd, and contrary to the hypothesis. There are, then, no other numbers smaller than A and B that are the least in the ratio of A to B; and consequently A and B are the least. Therefore numbers prime to one another are the least, and so on. Which was to be demonstrated.

THEOR. 22. PROPOS. 24. [Margin: xxij.]

The least of all numbers having the same ratio with them are prime to one another.

Let A and B be the least of all numbers having the same ratio with them. I say they are prime to one another — that is, that no number except unity measures them by a common measure. For if they are not prime to one another but have some number as a common measure, let the number C be their common measure, and let C measure A as many times as there are units in the number D, and measure B as many times as there are units in E. Now since C, taken as many times as there are units in D, produces A, and the same C, taken as many times as there are units in E, produces B, then D and E, multiplying C, produce A and B. [Margin: a — Axiom 9 [?]] Therefore the ratio of D to E will be the same as that of A to B. [Margin: b — VII.18] But since D and E, being parts of A and B, are smaller than A and B, then A and B will not be the least of all numbers having the same ratio with them — which is absurd. Therefore the numbers A and B are prime to

one another; and consequently the least of all numbers having the same ratio with them are prime to one another. Which was to be demonstrated.

A B
 C —————
 D ——— E —

SCHOLIVM

We shall extend this proposition, and the preceding one, following Campanus, to more numbers, in this way.

Any numbers whatever prime to one another are the least in the continuation of their proportions. And any numbers whatever that are the least in the continuation of their proportions are prime to one another.

Let A, B, C be any numbers prime to one another. I say they are the least in the continuation of their proportions, so that they cannot be continued in smaller numbers — even though the ratio of two of them may be found in smaller numbers. For if they are not the least, there will be some others smaller than them, say D, E, F, the least in the continuation of those proportions. Now since D, E, F are the least in the ratio of the numbers A, B, C, then D will measure A, E will measure B, and F will measure C equally, by what we demonstrated at proposition 21 of this book [Margin: VII.21] — and indeed by one and the same number, which let be G, so that D measures A, E measures B, and F measures C, as many times as there are units in G. Since, then, unity measures the number G just as the number D measures A, [Margin: a — VII.15] likewise unity measures the number D just as the number G measures A. And by the same reasoning the same G measures both B and C, just as unity measures E and F. Therefore A, B, C, since they have the number G as a common measure, are composite to one another. Which is absurd, and contrary to the hypothesis. Therefore there are no other numbers smaller than A, B, C that are the least in the continuation of the proportions of A to B and B to C; but A, B, C themselves are the least.

Now let A, B, C be the least in the continuation of their proportions. I say they are prime to one another. For if they are not prime to one another, let the number G measure them by a common measure, so that G measures A as many times as there are units in D, measures B as many times as there are units in E, and measures C as many times as there are units in F. Since, then, A, B, C are measured as many times as there are units in D, E, F, it follows that D, E, F, multiplying G, produce A, B, C and have the same ratios which A, B, C have, by

what we showed at proposition 18 of this book. [Margin: VII.18] And so, since D, E, F are smaller than A, B, C, then A, B, C will not be the least in the continuation of their proportions — which is absurd. Therefore A, B, C are prime to one another. Which is what was proposed.

A B C
D — E — F —
G —

THEOR. 23. PROPOS. 25. [Margin: xxiv.]

If two numbers be prime to one another, the number that measures one of them will be prime to the other.

Let A and B be prime to one another, and let the number C measure A. I say that C is prime to the other, B. For if B and C are not prime to one another, let the number D measure them by a common measure, if that be possible. Now since D measures C, and C measures A, [Margin: a — Axiom 11] D will also measure A. But it also measures B. Therefore A and B are not prime to one another, since they have the number D as a common measure — which is absurd, and contrary to the hypothesis. Therefore C is prime to B. In the same way, if some number measures B, it will be prime to A. Accordingly, if two numbers be prime to one another, etc. Which was to be demonstrated.

A B
C
D

THEOR. 24. PROPOS. 26. [Margin: xxv.]

If two numbers be prime to some number, then the number produced from them [their product] will also be prime to that same number.

Let each of the numbers A and B be prime to C, and let the number D be produced from A into B, or from B into A. I say that D too is prime to that same C. For if C and D are not prime to one another, let the number E be their common measure, measuring D as many times as there are units in the number F. Now since E, taken as many times as there are units in F, makes D, [Margin: a — Axiom 9] it follows that F, multiplying E, generates D; [Margin: b — VII.16] and conversely E, multiplying F, produces the same D. But this same D was generated from A into B. Therefore, since from E (first) into F (fourth) there arises the same number as from A (second) into B (third), [Margin: c — VII.19] it will be: as E (first) is to A (second), so B (third) is to F (fourth). But since A and C are prime to

one another, and E is supposed to measure C, [Margin: d — VII.25] E will be prime to A;

and so E and A will be the least in their ratio. [Margin: e — VII.23] Therefore they will measure B and F equally, since these have the same ratio — namely E measures B, as A measures F. [Margin: f — VII.21] And so, since E measures both B and C, then B and C will not be prime to one another — which is absurd, and contrary to the hypothesis. Therefore D will be prime to that same C; and consequently, if two numbers be prime to some number, etc. Which was to be demonstrated.

A B
 E
 C D
 F

THEOR. 25. PROPOS. 27. [Margin: xxvj.]

If two numbers be prime to one another, then the number produced from one of them [i.e., its square] will also be prime to the other.

Let A and B be prime to one another, and let C be produced from A into itself. I say that C is prime to the other, B. For if D be taken equal to A, then D too will be prime to B. Now since A and D are prime to B, [Margin: a — VII.26] the number produced from A into D — that is, produced from A into itself, namely C — will be prime to that same B. And by the same technique we shall show that the number produced from B into itself is prime to A. Therefore, if two numbers be prime to one another, etc. Which was to be demonstrated.

A ... B
 C
 D

THEOR. 26. PROPOS. 28. [Margin: xxvij.]

If two numbers be prime to two numbers, each to each, then the numbers produced from them [their products] will also be prime to one another.

Let each of A and B be prime to each of C and D, and let E be produced from A into B, and F from C into D. I say that E and F are prime to one another. For since each of A and B is prime to C, [Margin: a — VII.26] E, produced from them, will also be prime to that same C. Again, since each of A and B is prime to D, in the same way E, produced from them, will be prime to that same D. Now since each

of C and D is prime to E, [Margin: b — VII.26] F, produced from them, will also be prime to E. Therefore, if two numbers be prime to two numbers, each to each, etc. Which was to be shown.

A B ...
 E
 C ... D ..
 F

THEOR. 27. PROPOS. 29. [Margin: xxvii.]

If two numbers be prime to one another, and each multiplying itself makes some number [its square], then the numbers produced from them will also be prime to one another. And if the original numbers, multiplying those products, make some numbers [the cubes], these too will be prime to one another. And this will always come about with respect to the extremes.

Let A and B be prime to one another; and from A into itself let C be made, and from B into itself let D be made. I say that C and D too are prime to one another. And if again E be made from A into C, and F from B into D, I say that E and F are likewise prime to one another. For since A and B are prime to one another, [Margin: a — VII.27] C, made from A into itself, will be prime to the other, B; and in the same way, since B and C are prime to one another, D, made from B into itself, will be prime to C; and so the two products C and D will be prime to one another.

AGAIN, since A and B are prime to one another, [Margin: b — VII.27] C, made from A into itself, will be prime to B, and D, produced from B into itself, will be prime to A. But C has also been shown prime to D. Therefore each is prime to each; [Margin: c — VII.28] and consequently E, made from A into C, will be prime to F, made from B into D. And if further G be made from A into E, and H from B into F — since A and C are prime to B, [Margin: d — VII.26] E, produced from them, will be prime to B; and by the same reasoning F will be prime to A. Now since each of A and E is prime to each of B and F, [Margin: e — VII.28] G, made from A into E, will be prime to H, made from B into F. And so on in succession, if there be more. For in the same way, since A and E are prime to B, [Margin: f — VII.26] G, made from them, will be prime to B, and likewise H to A. [Margin: g — VII.28] Therefore I, produced from A into G, will be prime to K, produced from B into H, since each of A and G is prime to each of B and H. And so, if two numbers be prime to one another, etc. Which was to be shown.

A ... B ..
 C D
 E F
 G, 81. H, 16.
 I, 243. K, 32.

THEOR. 28. PROPOS. 30. [Margin: xxix.]

If two numbers be prime to one another, then both together [their sum] will also be prime to each of them; and if both together be prime to some one of them, then the original numbers will also be prime to one another.

Let AB and BC be prime to one another. I say that both together, AC, is also prime both to AB and to BC. For if AC and AB are not prime to one another, let the number D measure them by a common measure, if that be possible. Now since D measures the whole AC and the subtracted part AB, [Margin: a — Axiom 12] it will also measure the remainder BC. Therefore AB and BC are not prime to one another, since the number D measures them — which is absurd, and contrary to the hypothesis. Therefore AC will be prime to AB. And in the same way we shall show it is prime to BC.

But now let both AB and BC together be prime to some one of them, namely to AB. I say that AB and BC are also prime to one another. For if they are not prime to one another, let the number D measure them, if that be possible. Now since D measures AB and BC, [Margin: b — Axiom 10] D will also measure the number AC, compounded of AB and BC; and consequently AC and AB are not prime to one another, since the number D measures them. Which is absurd, and contrary to the hypothesis. Therefore AB and BC are prime to one another.

A B C
 D ———

And by the same argument we shall show that AB and BC are prime to one another if AC be supposed prime to BC. Therefore, if two numbers be prime to one another, etc. Which was to be demonstrated.

COROLLARIVM

From this it follows that a number compounded of two numbers, which is prime to one of them, is also prime to the other. For if AC is prime to AB, then AB and BC will be prime to one another, by the second part of this proposition. Therefore AC will also be prime to BC, by the first part of the same. Which is what was proposed.

THEOR. 29. PROPOS. 31. [Margin: xxxij. [?]] — see anomaly (a)]

Every prime number is prime to every number which it does not measure.

Let the prime number A not measure the number B. I say that A is prime to B — that is, that A and B are prime to one another, even though B be composite. For if A and B are not prime to one another, let some number C, other than unity, measure them by a common measure, if that be possible. Then C will not be the same as A, since A is supposed not to measure B. Now since another number, C, measures the number A, A will not be prime — which is absurd, and contrary to the hypothesis. Therefore A is prime to B; and accordingly every prime number is prime to every number, etc. Which was to be demonstrated.

A B
C

THEOR. 30. PROPOS. 32. [Margin: xxxij. [?]] — see anomaly (a)]

If two numbers, multiplying one another, make some number, and some prime number measures the number produced from them, then it will also measure one of the original numbers.

Let the two numbers A and B, multiplying one another, make C, and let the prime number D measure C. I say that D measures at least one of A and B, if it does not measure both. For let D not measure A, but let it measure C as many times as there are units in the number E, so that C is made from D into E — the same C that was made from A into B. Now since the number produced from D (first) into E (fourth) is equal to the number produced from A (second) into B (third), [Margin: a — VII.19] it will be: as D (first) is to A (second), so B (third) is to E (fourth). But since the prime D is prime to A, because it does not measure it, [Margin: b — VII.31] [Margin: c — VII.23] D and A will be the least in their ratio. [Margin: d — VII.21] Therefore they will measure B and E equally — namely D measures B, and A measures E. And consequently, if D does not measure A, it will measure at least B; and in the same way, if D does not measure B, it will measure at least A. Therefore, if two numbers, multiplying one another, make some number, etc. Which was to be demonstrated.

A B
 C
 D E

SCHOLIVM

In the same way we shall demonstrate the following theorem too.

If two numbers, multiplying one another, make some number, and some non-prime number measures the number produced from them — or at any rate is composite with respect to it — then it will also be composite with respect to one of the original numbers.

For from A into B let C be made, which some non-prime number D either measures, or at any rate is composite with respect to it — that is, D and C are composite to one another. I say that D too is composite with respect to one of A and B — that is, that either D and A, or D and B, are composite to one another. For if D is composite with respect to neither of them, then each of A and B will be prime to D. [Margin: a — VII.26] Therefore C, produced from them, will also be prime to that same D — which is absurd, since D was supposed either to measure the number G [recte: C] or at any rate to be composite with respect to it. Therefore D is composite with respect to A or to B, since it is not prime to both.

A . . . B
 C
 D

PROBL. 31. PROPOS. 33. [Margin: xxx.]

Every composite number is measured by some prime number.

Let A be a composite number. I say that some prime number measures it. For let the number B measure it; if B is prime, we have what was proposed. But if it is composite, let the number C measure it, which will be either prime or composite. If it is prime, then since it measures B, and B measures A, [Margin: a — Axiom 11] C, being prime, will also measure A. But if C is composite, another number will measure it. And since a number is not diminished infinitely, we shall at last arrive at some number which no other measures — that is, at a prime — which, since it measures all the preceding, [Margin: b — Axiom 11] will also measure the composite A. Which is what was proposed.

A
 B C . . .

ANOTHER WAY. Since the number A is composite, some number — or even several — will measure it. Let B be the least of all those measuring it, which I say is prime. For if B is not prime, let the number C measure it, if that be possible. Then since C measures B, and B measures A, [Margin: c — Axiom 11] C, which is smaller than B, will also measure A — which is absurd, since B was supposed the least of all those measuring it. Therefore the number B is prime. Therefore every composite number is measured by some prime number. Which was to be demonstrated.

A
 B ... C —

THEOR. 32. PROPOS. 34. [Margin: xxxj.]

Every number is either prime, or is measured by some prime number.

[Demonstration of Proposition 34, continued from the preceding page. The enunciation — "Every number is either prime, or is measured by some prime number" — was given at the end of the previous page.]

Let A be any number whatever.

A.....

I say that it is either prime, or else some prime number measures it. For every number is either prime or composite: if A is prime, we have what was proposed; but if it is composite, then some prime number measures it [Margin: a | 33.sept — i.e. *Elements* VII.33]. Therefore every number is either prime, or else some prime number measures it. Which was to be shown.

PROBL. 3. PROPOS. 35. [Margin: xxxiiij.]

Given any quantity of numbers whatever, to find the least of all the numbers that are in the same ratio with them.

Let A, B, C be any number of numbers whatever, holding any ratios—whether the ratio of A to B is the same as that of B to C, or not—and let it be required to find just as many numbers that are the least in the same ratios.

D..
 A..... B.... C.....
 E... F.. G....
 H — I — K —
 L —.

Now A, B, C are either prime to one another or composite. If they are prime to one another, then they themselves are the least in the sequence of their ratios, by what we demonstrated at proposition 24 of this book. But if they are not prime to one another, let the greatest common measure of them be found—the number D, which measures A, B, C by the numbers E, F, G [Margin: a | 3.sept — *Elements* VII.3]. I say that E, F, G are the least in the ratios of the numbers A, B, C.

That they have the same ratios as the numbers A, B, C is shown thus. Since D measures A, B, C by E, F, G, it follows that D, multiplying E, F, G, produces A, B, C [Margin: b | 9.pron — Axiom 9]. Therefore, by what we showed at proposition 18 of this book, E, F, G will have the same ratios as the numbers A, B, C.

That E, F, G are the least of all the numbers having the same ratio with them will become clear in this way. If they are not the least, there will be some other numbers, smaller than they, that are the least in the same ratios. So let there be, if possible, the least numbers H, I, K; and since these measure A, B, C, let them measure them by the number L. On this supposition, it follows that L, multiplying the numbers H, I, K, produces the numbers A, B, C [Margin: c | 9.pron — Axiom 9]; and conversely L measures A, B, C by H, I, K [Margin: d | 8.pron — Axiom 8]. Now since E, as the first term multiplying D, makes the fourth term A, while H, as the second term multiplying L, makes that same A as the third product, it follows that as E, the first, is to H, the second, so is L, the third, to D, the fourth [Margin: e | 19.sept — *Elements* VII.19]. But E is greater than H. Therefore L too will be greater than D; and so, since L measures A, B, C, D will not be the greatest common measure of the numbers A, B, C. This is absurd and contrary to the hypothesis. Therefore there will be no other numbers, smaller than E, F, G, that are the least in the sequence of the ratios of A to B and B to C; rather E, F, G themselves are the least. Hence, given any quantity of numbers, we find the least, and so on. Which was to be done.

COROLLARIVM

From this it follows that the greatest measure of any set of numbers measures them by numbers that are the least of all those having the same ratio with them. For it has been shown that the numbers E, F, G—by which D, the greatest measure of A, B, C, measures A, B, C—are the least in the sequence of the ratios of A to B and B to C. And the same holds in the remaining cases.

SCHOLIVM

From these results we shall easily find, by a simple route, the two least numbers that have the same ratio as any given set of continuously proportional numbers.

For example, suppose the continuously proportional numbers A, B, C, D, E are proposed—whether or not they are the least in the sequence of the ratio of A to B: we shall find the two least numbers in the same ratio if, by means of this problem, we take F and G, the least in the ratio of the two numbers A and B, namely those by which I, their greatest common measure, measures them.

A, 16. B, 24. C, 36. D, 54. E, 81.
 I, 8.
 F, 2. G, 3.

It sometimes happens, however, that one of the numbers E, F, G found by this proposition is a unit—namely when D, the greatest measure, is equal to one of the numbers A, B, C, as is clear from these examples:

A... B..... C..... A.... B.. C.....
 D... D..
 E. F.. G... E.. F. G...

And it is then evident that the numbers E, F, G so found are the least in the sequence of their ratios, since no number smaller than a unit can be given.

PROBL. 4. PROPOS. 36. [Margin: xxxvj.]

Given two numbers, to find the least number that they measure.

Let it be required to find the least of all the numbers that the given numbers A and B measure. First let the given numbers A and B be prime to one another, and let them, multiplying each other, make C.

A.... B.....
 C.....
 D ————.
 E — F —

I say that C is the least number that A and B measure. That they measure it is evident. For since C is produced from A into B, or from B into A, A measures C by B, and B measures that same C by A [Margin: a | 7.pron — Axiom 7]. Both A and B, therefore, measure C. That C is the least of all the numbers that A and B measure we shall demonstrate as follows. If C is not the least, let A and B measure, if possible, another number D smaller than C; and let A measure D by E, and B measure that same D by F. On this supposition, D is produced both from A into E and from B into F, and conversely [Margin: b | 9.pron — Axiom 9]. Now since the same number D is made from A (the first term) into E (the fourth), and from B (the second) into F (the third), it follows that as A, the first, is to B, the second, so is F, the third, to E, the fourth [Margin: c | 19.sept — *Elements* VII.19].

Therefore A and B—since they are supposed prime to one another, and for that reason the least in their ratio [Margin: d | 23.sept — *Elements* VII.23]—measure F and E equally [Margin: e | 21.sept — *Elements* VII.21], namely A measures F and B measures E.

For since A, multiplying B and E, makes C and D, it follows that C is to D as B is to E [Margin: f | 17.sept — *Elements* VII.17]. And accordingly, since B measures E, as was shown, C, the greater number, will also measure D, the smaller. Which is absurd. Therefore A and B will not measure any number smaller than C; and so C is the least of all the numbers they measure.

Next, let the given numbers A and B not be prime to one another. Let C and D be found, the least in the same ratio, so that there are four proportional numbers, namely A is to B as C is to D [Margin: g | 35.sept — *Elements* VII.35]. On this supposition, the same number is made from A (the first term) into D (the fourth), and from B (the second) into C (the third) [Margin: h | 19.sept — *Elements* VII.19]. So let it be made, and call it E. I say that E, produced in this way, is the least number that A and B measure. That they measure it is manifest. For since E is produced both by A multiplied by D and by B multiplied by C, both A and B measure E [Margin: i | 7.pron — Axiom 7]. That E is the least of all the numbers that A and B measure will be proved thus. If E is not the least, let A and B measure, if possible, another number F smaller than E; and let A measure that F by G, and B measure that same F by H. On this supposition, F is made both from A into G and from B into H [Margin: k | 9.pron — Axiom 9]. Now since the same number F is made from A (the first) into G (the fourth) and from B (the second) into H (the third), it follows that as A, the first, is to B, the second, so is H, the third, to G, the fourth [Margin: l | 19.sept — *Elements* VII.19]. Therefore C and D, since they are the least in the ratio of A to B, or of H to G, measure H and G equally [Margin: m | 21.sept — *Elements* VII.21], namely C measures H and D measures G. And since A, multiplying D and G, makes E and F, it follows that E is to F as D is to G [Margin: n | 17.sept — *Elements* VII.17]. And accordingly, since D measures G, as was shown, E, the greater number, will also measure F, the smaller. Which is absurd. Therefore A and B will not measure any number smaller than E; and so E is the least of all the numbers they measure. Hence, given two numbers, we find the least number that they measure. Which was to be done.

COROLLARIVM

From this it follows that if two numbers multiply the least numbers having the same ratio—the greater multiplying the smaller and the smaller the greater—the

number produced is the least that they measure. For, given C and D as the least in the ratio of A to B, it was demonstrated that the number E—formed from A (the smaller) into D (the greater), and from B (the greater) into C (the smaller)—is the least number that A and B measure.

SCHOLIVM

This corollary, in Campanus, is proposition 35 of this seventh book. And the following proposition, in the same author, is the corollary to proposition 35.

THEOR. 33. PROPOS. 37. [Margin: xxxvi.]

If two numbers measure some number, then the least number that they measure will also measure that same number.

Let two numbers A and B measure any number CD, and let E be another number, the least that these same A and B measure.

A... B...
C..... F — D
E.....

For if E does not measure CD, then when E is subtracted from CD as many times as it can be taken away, some number smaller than E will be left over. So let E, subtracted from CD as often as possible, leave—if it can—a number FD smaller than itself, such that E measures the part taken away, CF. Now since both A and B measure E, and E measures CF, both A and B measure CF as well [Margin: a | 11.pron — Axiom 11]. Therefore, since A and B measure the whole CD and the part taken away, CF, they also measure the remainder FD [Margin: b | 22.pron — Axiom 22]. But FD is smaller than E. So E is not the least number that A and B measure—which is absurd and contrary to the hypothesis. Therefore E measures CD. So if two numbers measure some number, and so on. Which was to be demonstrated.

PROBL. 5. PROPOS. 38. [Margin: xxxvj.]

Given three numbers, to find the least number that they measure.

Let it be required to find the least number that three given numbers A, B, C measure. When D, the least number that the two numbers A and B measure, has been found [Margin: a | 36.sept — *Elements* VII.36], the remaining number C either measures that same D or does not. First let C measure D, so that all three numbers A, B, C measure D.

A... B.... C.....
D.....
E _____

I say that the number D, found as the least that A and B measure, is also the least that the three numbers A, B, C measure. For if D is not the least, let A, B, C measure, if possible, another number E smaller than D. Then, since A and B measure E, which is smaller than D, D will not be the least number that A and B measure—which is absurd and contrary to the hypothesis. Indeed, since A and B measure E, and D is the least that these same A and B measure, D, the greater, will also measure E, the smaller [Margin: b | 31.sept — *Elements* VII.31]. Which is absurd.

But now let C not measure D as found. Then, when E, the least number that C and D measure, has been found [Margin: c | 36.sept — *Elements* VII.36], I say that E is the least number that A, B, C measure.

A.. B... C....
D.....
E.....
F _____

That they measure it is shown thus. Since A and B measure D, and D measures E, A and B also measure E [Margin: d | 11.pron — Axiom 11]. But C also measures that same E. Therefore all three numbers A, B, C measure E. That E is the least that A, B, C measure will be proved in this way. If E is not the least, let A, B, C measure, if possible, another number F smaller than E. Then, since A and B measure F, the number D—namely the least found that the numbers A and B measure—also measures that same F [Margin: e | 37.sept — *Elements* VII.37]. And so, since C and D measure F, which is smaller than E, E will not be the least that C and D measure—which is absurd and contrary to the hypothesis. Indeed, since C and D measure F, the number E—the least that these same C and D measure—will also measure F, the greater measuring the smaller [Margin: f | 37.sept — *Elements* VII.37]. Which is absurd. Therefore A, B, C will not measure any number smaller than E; rather E itself is the least. Hence, given three numbers, we find the least number that they measure. Which was to be done.

COROLLARIVM

From these results it follows that if three numbers measure some number, then the least number that they measure also measures it. For in the last part of this demonstration, from the fact that A, B, C were supposed to measure F, it was shown that E—the least that A, B, C measure—also measures that same F.

SCHOLIUM

We can show this corollary in another way, exactly as in proposition 37 of this book. For let A, B, C measure any number DE, and let F be the least that these same A, B, C measure.

A. B... C....

D..... G — E

F.....

I say that F also measures DE. For if it does not, let it measure a part DG of it and leave a remainder GE smaller than itself. Now since A, B, C measure F, and F measures DG, A, B, C also measure that same DG [Margin: g | 11.pron — Axiom 11]. And accordingly, since they are supposed to measure the whole DE as well, they will also measure the remainder GE, which is smaller than F [Margin: h | 12.pron — Axiom 12]. Therefore F will not be the least that A, B, C measure—which is absurd and contrary to the hypothesis. So F measures DE.

By the same reasoning, given more numbers than three, we shall find the least number that they measure, and this same corollary will hold. For if the given numbers are four, one must first find the least that three of them measure; if five, the least that four measure, and so on. Everything else is to be carried out as was said for three numbers.

THEOR. 34. PROPOS. 39. [Margin: xxxvij.]

If some number measures a number, then the number it measures will have a part named after the measuring number.

Let the number B measure the number A. I say that A has some part named after B.

A.....

B.... C...

For let B measure A as many times as there are units in the number C. Since, then, the unit measures C just as B measures A [Margin: a | 15.sept — *Elements* VII.15], the unit is accordingly the same part of B that C is of A. But the unit is a part of B named after B, as we taught at definition 2 of this book. Therefore C too is a part of A, named after that same B. So if some number measures a number, and so on. Which was to be shown.

THEOR. 35. PROPOS. 40. [Margin: xxxvii.]

If a number has any part whatever, then the number named after that part will measure it.

Let the number A have a part B, after which the number C is named. I say that C measures A.

A.....
B... C.....

For since the part B is named after C, and the unit is likewise a part of C named after that same C, the unit measures C just as B measures A. Conversely, then, the unit measures B just as C measures A [Margin: a | 15.sept — *Elements* VII.15]. So if a number has any part whatever, and so on. Which was to be demonstrated.

PROBL. 6. PROPOS. 41. [Margin: xxxix.]

To find a number which, being the least, has given parts.

Let the given parts be A, B, C, and let it be required to find the least number having the given parts. Let the numbers named after the parts A, B, C—that is, the numbers that name them—be D, E, F; and let G be the least number that D, E, F measure [Margin: a | 38.sept — *Elements* VII.38].

D.. A, Secunda [a half]
E... B, Tertia [a third]
F.... C, Quarta [a fourth]
G.....
H —————

I say that G is the least number having the given parts A, B, C. That it has such parts is shown thus. Since D, E, F measure G, G has parts named after D, E, F [Margin: b | 39.sept — *Elements* VII.39]—that is, the parts A, B, C, since these are named after D, E, F. And that G is the least having those parts is clear. For if it is not the least, let H, smaller than G, have, if possible, the same parts A, B, C. Then, since H has the parts A, B, C, the numbers D, E, F—named after the parts A, B, C—measure it [Margin: c | 40.sept — *Elements* VII.40]. And so, since H is smaller than G, G will not be the least that D, E, F measure—which is absurd and contrary to the hypothesis. Therefore no number smaller than G will have the given parts A, B, C; rather G itself is the least. Hence we have found a number which, being the least, has the given parts. Which was to be done.

SCHOLIUM (to Proposition 41, continued)

[Clavius's commentary, continuing the scholium begun on the previous page.]

If we take the numbers I, K, L by which the numbers D, E, F measure G, then I, K, L will be the given parts A, B, C of G — that is, the parts named after D, E, F. For since D, E, F measure G by way of I, K, L, the unit measures I, K, L in the same way that the numbers D, E, F measure G. [Margin: VII.15] Conversely, then, the unit measures D, E, F just as the numbers I, K, L measure G; and so the unit is the same part of D, E, F as the numbers I, K, L are of G. Since, therefore, the unit is a part of D, E, F named after them, I, K, L will likewise be parts of G named after D, E, F.

A, Second D.. I.....

B, Third E... K.... [Margin: VII.15]

C, Fourth F.... L...

G.....

From this it follows that the least number which any given numbers measure is the least having parts named after the measuring numbers. For it has been shown that G — the least number that D, E, F measure — is the least that has the parts A, B, C, which are I, K, L, named after the measuring numbers D, E, F.

Now, as Campanus says, if the least number found having the given parts is doubled, tripled, and so on, we obtain the second number after the least, then the third, the fourth, and so on, each containing the same parts. For once G, the least, has been found having the parts A, B, C named after D, E, F, let its double be the number H, its triple I, and so on. I say that H is the second number that has these same parts A, B, C named after the numbers D, E, F, that I is the third, and so on — so that neither between G, the least, and its double H, nor between H, the double, and I, the triple, and so on, does any other number fall having the same parts; rather, H, I alone and the remaining multiples of G contain the said parts. That H and I, and so on, have the parts A, B, C named after D, E, F, we show as follows. Since D, E, F measure G, by construction, and G measures H, I, and the remaining multiples of G, [Margin: Axiom 11] D, E, F will also measure those same numbers H, I and the remaining multiples of G. [Margin: VII.39] Therefore H, I and the remaining multiples of G will have parts named after the measuring numbers D, E, F — namely the parts posited as A, B, C.

A, D..

B, E...

C, F....

G.....

H.....

I.....

K----- M----- L [Margin: Axiom 11]
 N----- P----- O [Margin: VII.39]

That H, the double of the least G, is the second number having those parts, we shall demonstrate in this way. If H is not the second, let there be, if possible, another number KL prior to it — that is, one greater than the least G and less than H, the double of G. When G is subtracted from KL, let the remainder ML be less than G. Since, then, KL has the parts A, B, C, [Margin: VII.40] the numbers D, E, F, named after those parts, will measure it. And therefore G also, the least that D, E, F measure, will measure that same KL, by the corollary of Proposition 38 of this book. But G also measures the piece KM cut off, which is equal to itself. [Margin: Axiom 12] Therefore G will measure the remainder ML as well — the greater measuring the less. This is absurd. Therefore no other number falling between G and H has the parts A, B, C; and consequently H is the second number having parts of this kind.

In just the same way we shall show that I, the triple of G, is the third number having the said parts. For if it is not the third, let there be, if possible, another — say NO — prior to it, greater than H the double, but less than I the triple. When H, the double, is subtracted from NO, let the remainder PO be less than G. Since, then, NO has the parts A, B, C, [Margin: VII.40] the numbers D, E, F, named after those parts, will measure it. And for that reason G also, the least that D, E, F measure, will measure that same NO, by the corollary of Proposition 38 of this book. But G also measures NP, the piece cut off, which is equal to H the double. [Margin: Axiom 12] Therefore G will measure the remainder PO as well — the greater measuring the less. This is absurd. Therefore no other number falling between H and I has the given parts A, B, C; and consequently I is the third number having those parts. By the same reasoning the quadruple of G will be the fourth, the quintuple the fifth, and so on.

To this place may also be referred the following problem.

[Appended problem] To find a number which, being the least, has given parts under this condition: that each part contains the following part.

Let the given parts be A, B, C, and let it be required to find the least number that has them in this order, so that part A contains part B, and part B contains part C. Let D, E, F be the numbers named after the parts A, B, C. Let G be made from E multiplied into F, and H from D multiplied into G. I say that H is the least number sought.

A, Second B, Third C, Fourth
 D... E... F....

G.....
H.....

. Unit

I----- - - - -
K-----
L-----
M---

That it has the given parts in the aforesaid order is easily demonstrated. For since H is made from D multiplied into G, G will be contained in H as many times as the unit is in D. But the unit is a part of D, named after D itself. Therefore G too is a part of H, named after the same D; and so H has the part A — namely the number G — named after D. Next, since G is made from E multiplied into F, by the same reasoning F will be a part of G, named after E; and so A, the part of H (that is, the number G), has the part B — namely the number F — named after E. Finally, since F has the unit as a part named after F itself, it is clear that B, the part of G (namely the number F), also has the part C — named after F, namely the unit. Hence the number found, H, has the part A; part A has part B; and part B has part C.

That H is the least containing those parts in this order will be shown by the following reasoning. For if it is not the least, let a smaller number I, if possible, have the same parts in the same order, so that K is the part A of I, named after the number D; L the part B of K, named after E; and M the part C of L, named after F. Since, then, K is a part of I named after D, K will be contained in I as many times as the unit is in D; [Margin: Def. 15] and thus I will be produced from D multiplied into K. By the same reasoning K will be produced from E multiplied into L, and L from F multiplied into M. So, since D, multiplying G and K, produces H and I, [Margin: VII.17] it will follow that as H is to I, so is G to K. By the same reasoning, since G and K are produced from E multiplied into F and into L, as G is to K, so is F to L. And since F and L are produced from F multiplied into the unit and into M, as F is to L, so is the unit to M. Since, then, as H is to I, so G is to K; and as G is to K, so F is to L; and as F is to L, so the unit is to M — it will follow, by the lemma to Proposition 14 of this book, that as H is to I, so is the unit to M.

H. G. F. Unit
I. K. L. M

But H is assumed to be a number greater than the number I. Therefore the unit too will be greater than the number M — the part greater than the whole. This is

absurd. Therefore no number smaller than H has the parts A, B, C in the aforesaid order, but H itself is the least. Which was what was proposed.

But if there are more than three parts, exactly the same procedure and demonstration are to be followed. For example, if the numbers 2, 3, 4, 5, 6 are the denominators of the parts, then 30 will be produced from 5 into 6; 120 from 4 into 30; 360 from 3 into 120; and finally 720 from 2 into 360. For the number 720 will have a part named after 2; that part another named after 3; that another named after 4; that another named after 5; and that, finally, a part named after 6 — as is evident.

If we double, triple, and so on, the number H once it has been found, we shall obtain other numbers — the second, third, fourth, and so on — which have the same parts in the same order, though doubled or tripled, and so on. For G doubled or tripled, and so on, will be the half of H doubled or tripled, and so on — just as G is the half of H. And the same reasoning holds for the other parts.

FINIS ELEMENTI SEPTIMI

[End of the Seventh Element.]

EUCLID'S EIGHTH ELEMENT

[EVCLIDIS ELEMENTVM OCTAVVM]

THEOREM 1. PROPOSITION 1.

[Margin: i.]

If there are any number of numbers in continued proportion, and the extremes of them are prime to one another, then they are the least of all having the same ratio as they.

[Clavius's commentary.]

Let there be any numbers in continued proportion whatsoever — A, B, C, D — and let the extremes A and D be prime to one another. I say that A, B, C, D are the least of all having the same ratio as they. For if they are not the least, there will be others smaller than they, in the same ratio. Let there be, then, if possible, others smaller than they in the same ratio: E, F, G, H. Since, therefore, there are the numbers A, B, C, D, and others equal to them in multitude — E, F, G, H — taken two by two and in the same ratio, [Margin: VII.14] it will follow, *ex aequali* (by

equality of ratios), that as A is to D, so E is to H. [Margin: VII.23] But A and D are the least in their ratio, since they are assumed to be prime to one another. [Margin: VII.21] Therefore A will measure E, and D will measure H alike — the greater measuring the less. This is absurd. Therefore there are no numbers smaller than A, B, C, D in the same ratio as they, but they themselves are the least. And consequently, if there are any number of numbers in continued proportion, etc. Which was to be demonstrated.

A..... E--
 B..... F----
 C..... G---- [Margin: VII.14]
 D..... H----- [Margin: VII.23]
 [Margin: VII.21]

SCHOLIUM.

It is clear from the demonstration that the numbers A, B, C, D are the least in the continuation of their ratios — whether the extremes A and D are prime to one another, and whether A, B, C, D are in continued proportion (as Euclid intends) or not. This is shown by the following example, in which all the ratios are different, whereas in the previous one the same ratio is always found.

A.... E---
 B..... F----
 C..... G----
 D..... H----

PROBLEM 1. PROPOSITION 2.

[Margin: ij.]

To find the least numbers in continued proportion, as many as anyone may require, in a given ratio.

[Clavius's commentary.]

Let A and B be the least numbers of a given ratio, and let it be required first to find the three least numbers in the given ratio of A to B. Let A, multiplying itself and the number B, produce C and D. Then let B, multiplying itself, produce E. I say that C, D, E are the three least in the ratio of A to B. That they are proportional in the given ratio of A to B — that is, that as A is to B, so C is to D, and D to E — we show as follows. Since C and D are produced from A multiplied into A and into B, [Margin: VII.17] it will follow that as A is to B, so C is to D...

A.. B...
 C.... D..... E.....

F, 8. G, 12. H, 18. I, 27.
K, 16. L, 24. M, 36. N, 54. O, 81.

Euclid, *Elements* Book VIII — continued

(Continuation of the demonstration of Prop. 2: to find the least numbers in continued proportion, as many as you wish, in a given ratio. The worked instance uses $A = 2$, $B = 3$ (the given ratio $2 : 3$), from which come the three numbers $C = 4$, $D = 6$, $E = 9$; the four $F = 8$, $G = 12$, $H = 18$, $I = 27$; and the five $K = 16$, $L = 24$, $M = 36$, $N = 54$, $O = 81$.)

A .. B ...
C D E
F, 8. G, 12. H, 18. I, 27.
K, 16. L, 24. M, 36. N, 54. O, 81.

so that C is to D. Again, since D and E are produced when B is multiplied into A and into B, it likewise follows that as A is to B, so D is to E. [Margin: b, *Elements* VII.17] The three numbers C, D, E are therefore in continued proportion in the given ratio A to B. That they are also the least in that same ratio is shown as follows. The extremes C and E have been produced from A and B multiplied into themselves; and A and B are prime to one another, [Margin: c, *Elements* VII.24] because they are the least in their ratio. Hence the extremes C and E too will be prime to one another. [Margin: d, *Elements* VII.29 [?]] Therefore C, D, E are the least numbers in the ratio A to B. [Margin: e, *Elements* VIII.1]

Now let F, G, H be produced from A multiplied into the three numbers already found, C, D, E, and let I be produced from B multiplied into the last of them, E. I say that the four numbers F, G, H, I are the least in the same given ratio A to B. That they are proportional in the ratio A to B is shown thus. Since A, by multiplying C, D, E, produced F, G, H, these numbers F, G, H will have — by what we established at Prop. 18 of Book 7 — the same ratios as C, D, E, that is, the ratio that A has to B. [Margin: f, *Elements* VII.18] Again, since A and B, by multiplying E, produced H and I, it likewise follows that as A is to B, so H is to I. F, G, H, I are therefore in continued proportion in the given ratio A to B. [Margin: g, *Elements* VII.24] That they are the least in the given ratio becomes plain as follows. Since A and B, being the least in their ratio, are prime to one another, and since C and E were produced from A and B multiplied into themselves, and since F and I in turn were produced from A and B into C and E — F, that is, from A into C, and I from B into E — the extremes F and I too will be prime to one another. [Margin: h, *Elements* VII.29 [?]] Hence F, G, H, I are the least in their ratio, which is A to B. [Margin: i, *Elements* VIII.1]

In just the same way, if from A multiplied into the four numbers found, F, G, H, I, there arise K, L, M, N, and from B into the last, I, there arises O, then K, L, M, N, O will be five least numbers in the given ratio A to B. By the same procedure we shall find six, seven, eight, and so on. In this way we obtain the least numbers in continued proportion, and so forth. Which was to be done.

Scholium

(A second route to the same numbers, working downward from B rather than upward from A.)

A .. B ...
 C D E
 F, 8. G, 12. H, 18. I, 27.
 K, 16. L, 24. M, 36. N, 54. O, 81.

By the same method the four least proportional numbers will be produced from the multiplication of B into the three numbers found, E, D, C, and from the multiplication of A into C. For let I, H, G be produced from B into E, D, C, and F from A into C. Once this is done, [Margin: k, *Elements* VII.18] the numbers F and G will have the same ratio as A and B, since A and B, by multiplying C, produced F and G. Likewise G, H, I will — by what we demonstrated at Prop. 18 of this book — stand in the same ratio as C, D, E, that is, in the ratio of A to B, since B, by multiplying C, D, E, produced G, H, I. Therefore F, G, H, I are in the same ratio as A to B. That they are the least will be shown as before.

In just the same way, if from B multiplied into the four numbers found, I, H, G, F, there arise O, N, M, L, and from A into F there arises K, then K, L, M, N, O will be five least numbers in the given ratio A to B. By the same procedure we shall find six, seven, eight, and so on. Thus, whether A is multiplied into all the numbers found and B into the last, or B into all those found and A into the first, there will always be produced more numbers, and least numbers, in the same given ratio A to B. For Euclid demonstrated that the four numbers F, G, H, I are produced from A into C, D, E and from B into E; whereas we have shown that these same numbers are produced from B into E, D, C and from A into C.

Corollary I

From this it follows that, if three least numbers are in continued proportion, their extremes are squares; and if there are four, they are cubes. For of the three least numbers C, D, E the extremes C and E were made from A and B multiplied into themselves, and are therefore equal-times-equal; hence by Definition 18 they are squares. In the same way, of the four least numbers F, G, H, I the extremes F and I

are generated from A and B — the sides — multiplied into C and E, the squares of A and B respectively; that is, the number F is produced from the mutual multiplication of the three equal numbers A, A, A, and the number I from the mutual multiplication of the three equal numbers B, B, B, so that each is equal-times-equal-times-equal. By Definition 19, therefore, they are cubes.

Likewise, if there are five least numbers in continued proportion, their extremes will be squares of squares; and so, if there are still more, their extremes will be numbers under yet other names, of the kind usually explained in algebra. All this is evident from the multiplications by which the proportional numbers are generated in accordance with this proposition.

Nor can anyone object that this corollary holds only for three or four least numbers in continued proportion found by the technique taught in this proposition, and not for any three or four least numbers in continued proportion however proposed. No one can say this, because any given three or four least numbers in continued proportion are exactly equal to those found by this proposition. For if the given numbers were smaller than those found, the ones found would not be the least, which is contrary to this proposition; and if the given numbers were larger than those found, then the given ones would not be the least, which is contrary to the hypothesis. This will be made perfectly clear as follows.

A — B — C —
D, 2. E, 3.
F, 4. G, 6. H, 9.

Let three least numbers A, B, C in continued proportion be given. Taking the two least numbers D, E in the ratio A to B or B to C, from the scholium to Prop. 35 of Book 7, let there be found by this proposition, from these two least numbers D, E, the three least numbers F, G, H in the same ratio. I say that the three given numbers A, B, C do not differ from the three found, F, G, H. For A will necessarily be equal to F; and so, since as A is to B, so F is to G, it will also follow, by alternation, that as A is to F, so B is to G. Hence, if A is equal to F, B too will be equal to G; and by the same reasoning we shall show that C is equal to H. Therefore the three numbers A, B, C are equal, each to each, to the three numbers F, G, H. The same reasoning holds for four or more. But if A were said to be smaller than F, we should show by the same argument that B and C too are smaller than G and H; and then F, G, H would not be the least — which is absurd and contrary to this proposition. And if A were granted larger than F, then by the same argument B and C too would be larger than G and H, and so A, B, C would not be the least — which is contrary to the hypothesis. Since, then, A is neither

smaller nor larger than F, it is altogether equal to it; and therefore, as has been shown, B and C too will be equal to G and H. Which is what was proposed.

Corollary II

It is likewise plain that the extreme numbers of any set of proportionals found, according to this proposition, as least numbers in a given ratio, are prime to one another. This we shall easily show from the multiplications by which the proportional numbers are produced, and from Prop. 29 of Book 7 — just as it was demonstrated of the extreme numbers C, E and F, I, and so on.

Corollary III

It is settled, moreover, that the two least numbers in a given ratio measure all the middle numbers, however many, of the least set in that same ratio; for these middle numbers are produced by the multiplication of the two least into certain other numbers. Thus, in the given example, the middle number D is produced from A into B; the middle numbers G, H from A into D and E, or from B into C and D; likewise the middle numbers L, M, N from A into G, H, I, or from B into F, G, H — as is apparent both from Euclid's demonstration and from the one we set out in the scholium.

Scholium

Since both the numbers A, C, F, K and the numbers B, E, I, O are, by construction, in continued proportion from unity — the ratios of the former being reckoned by the number A, those of the latter by B, as will be shown more clearly at Prop. 9 of this book — it comes about that the extreme numbers of any set of least numbers in continued proportion are the last terms of as many numbers in continued proportion from unity, reckoned by the least numbers of the given ratio, as there are least proportionals proposed. Thus in the example above you see that C and E, the extremes of the three numbers in continued proportion, are the last of three numbers in continued proportion from unity, whose ratios are reckoned by A and B; while F and I, the extremes of the four in continued proportion, are the last of four numbers in continued proportion from unity, and so on. Hence, if anyone wishes to find any number of least whole numbers in a given ratio in continued proportion — the task being an easy one, since it begins from unity — he will readily accomplish it by this route. Once the two least numbers in the given ratio have been found, let there be taken, from unity, as many numbers in continued proportion, in the ratio reckoned by the smaller of those two, as there are least numbers proposed to be found. For the last of those numbers in

continued proportion from unity will be the first of the proportionals to be found; and if this is multiplied by the denominator of the given ratio, the second will be generated; and if this in turn is multiplied by the same denominator, the third will be generated; and so on. For example, if one wants eight least numbers in the sesquialter ratio: having found the two least numbers in the sesquialter ratio, 3 and 2, one must take eight numbers from unity in continued proportion in the double ratio, whose denominator is 2, in this manner: 1. 2. 4. 8. 16. 32. 64. 128. For the last of these, 128, will be the first of the eight numbers to be found, which, when multiplied by the denominator, [gives] 128. 192. 288. 432. 648. 972. 1458. 2187 — if the greater numbers are referred to the smaller. And the same holds for the rest.

Boethius [Boethius] and others explain this rule in the same way, as we too set it out in Book 5, in our treatment of proportions. Let there be taken, from unity, as many continued multiples according to the denomination of the aliquot part mentioned in the given ratio as there are continued proportionals to be found in the given ratio; for the last number will be the first of those to be found. Thus in the given example, since eight least numbers in the sesquialter ratio are wanted, one must take eight double numbers from unity, as before, which are reckoned by the denominator of the second, or half, part mentioned in [the name] "sesquialter" — that is, by 2. And if five least numbers in the sesquiquintan ratio are wanted, one must take five quintuple numbers from unity, as here: 1. 5. 25. 125. 625. For 625 is the first of the five numbers in the sesquiquintan ratio, as appears here: 625. 750. 900. 1080. 1296. And so for the rest. Furthermore, by this technique it is impossible to find — surprising as it may seem — more continued proportionals than were proposed. For after 1296 in the last example no other number will be found that has to 1296 the sesquiquintan ratio; just as in the earlier example no other number can be found after 2187 that has to 2187 the sesquialter ratio. The reason for this is that the extremes found by this technique are prime to one another, as is clear from the demonstration. For it thus comes about that the last term cannot stand to any other number as the first stands to the second — as will be demonstrated at Prop. 17 of Book 9.

THEOR. 2. PROPOS. 3.

[Margin: iij.]

If there are any number of least numbers in continued proportion among all that have the same ratio with them, their extremes are prime to one another.

A, 8. B, 12. C, 18. D, 27.
E, 2. F, 3.
G, 4. H, 6. I, 9.
K, 8. L, 12. M, 18. N, 17. [recte: 27]

Let A, B, C, D be least numbers in continued proportion. I say that the extremes A and D are prime to one another. For let two least numbers E, F be found in the ratio A to B, or B to C, or C to D. Then, by the route of the preceding problem, let three least numbers G, H, I be found in the same ratio, and also four, K, L, M, N, and so on, until the multitude K, L, M, N equals the multitude A, B, C, D. Now since A, B, C, D are the least in their ratio, and K, L, M, N have likewise been taken as the least in the same ratio, equal in multitude to them, they will be equal each to each — lest numbers smaller than the least be assigned in the same ratio — namely A to K and D to N. This we demonstrated geometrically at the end of Corollary 1 of the preceding proposition. But by Corollary 2 of the preceding proposition K and N are prime to one another. Therefore A and D too are prime to one another. And so, if there are any number of least numbers in continued proportion among all that have the same ratio with them, and so forth. Which was to be shown.

Scholium

This proposition is to be understood of least numbers in *continued* proportion, as can be seen from its demonstration and from Euclid's words. For if A, B, C, D were not in continued proportion, it would be impossible, by the preceding problem, to find K, L, M, N, an equal number of least terms in the same ratio. Indeed, if the ratios are diverse, there will sometimes be given least numbers successively proportional — that is, continued in their several diverse ratios — whose extremes are not prime to one another. For these numbers, 6. 10. 13 [?]. 18, are the least in the continuation of their ratios, and yet the extremes 6 and 18 are composite with respect to one another. This theorem, then, is the converse of the first theorem, so far as it concerns numbers in continued proportion. For any number of continued proportionals whose extremes are prime to one another are the least in their ratio, as is clear from the first theorem; and conversely, the extreme numbers of any set of least continued proportionals are prime to one another, as has here been demonstrated. But the first theorem, in so far as it regards numbers *not* in continued proportion, cannot be converted. For although any number of numbers not in continued proportion,

whose extremes are prime to one another, may be the least in the continuation of their ratios — as is clear from the scholium to Prop. 1 of this book — nevertheless it is not always true, conversely, that the extreme numbers of any set of least

numbers not in continued proportion are prime to one another, as is evident in the example just brought forward, 6. 10. 13 [?]. 18.

PROBL. 2. PROPOS. 4.

[Margin: iv.]

Given any number of ratios in least numbers, to find the least numbers in continued proportion in the given ratios.

Let there first be given two ratios in least numbers, A to B and C to D; and let it be required to find three least numbers in continued proportion in the given ratios.

A, 6. B, 5. C, 4. D, 3.
H, 4. F, 24. E, 20. G, 15.
I — K — L —

Having found the least number E, which B and C — the second and third terms — measure, [Margin: a, *Elements* VII.36] let A measure F as many times as B measures E; and let G be measured by D as many times as C measures that same E. I say that F, E, G are the least in the given ratios. That they have the given ratios in succession we show thus. Since A and B measure F and E equally, that is, by the same number, let them measure by H. This being posited, A and B, multiplying H, will produce F and E. [Margin: b, Axiom 9] Hence, as A is to B, so F is to E.

[Margin: c, *Elements* VII.18] By the same reasoning, since C and D measure E and G equally, it will be that as C is to D, so E is to G. Therefore F, E, G are in continued proportion in the ratios A to B and C to D. That they are the least will be plain as follows. If they are not the least, there will be some numbers smaller than they, each to each, in the same ratios: let these be, if possible, I, K, L. Since A and B are the least in their ratio, they will measure I and K equally, these being in the same ratio — namely B measuring K, the consequent measuring the consequent.

[Margin: d, *Elements* VII.21] And by the same reasoning C and D will measure K and L equally — namely C measuring K, the antecedent measuring the antecedent. Therefore, since B and C both measure K, the least number E, which B and C measure, will also measure that same K — the greater measuring the smaller. [Margin: e, *Elements* VII.37] Which is absurd. There will therefore be no other numbers smaller than F, E, G in the ratios A to B and C to D; and consequently F, E, G are the least in the given ratios.

Let there next be given three ratios in least numbers, A to B, C to D, and E to F; and let four least numbers in continued proportion in the given ratios be required.

A, 6. B, 5. C, 4. D, 3. E, 5. F, 7.
H, 24. G, 20. I, 15. K, 21.
L — M — N — O —

Having again found the least number G, which B — the second term — and C — the third — measure, [Margin: f, *Elements* VII.36] let A measure H as many times as B measures G; and let D measure I as many times as C measures that same G. This done, either E measures I or it does not. Let it first measure it; and let F measure K as many times as E measures I. I say that H, G, I, K are the least in the given ratios. That they are in continued proportion in the given ratios is settled. For since A and B measure H and G equally, it will be, as before, that as A is to B, so H is to G. By the same reasoning it will be that as C is to D, so G is to I; and as E is to F, so I is to K — since C and D measure G and I, and E and F measure I and K, equally. Therefore H, G, I, K are in continued proportion in the given ratios. That they are the least we show thus. If they are not the least, let there be, in the same ratios, numbers smaller than they, each to each, if possible: L, M, N, O. Since A and B are the least in their ratio, they will measure L and M equally, these having the same ratio — namely B, the consequent, measuring the consequent M. [Margin: g, *Elements* VII.21] In the same way C and D will measure M and N equally — namely C, the antecedent, measuring the antecedent M. And so, since B and C both measure M, the least number G, which B and C measure, will also measure that same M — the greater measuring the smaller. [Margin: h, *Elements* VII.37] Which is absurd. There will therefore be no other numbers in continued proportion in the given ratios smaller than G, H, I, K; and hence H, G, I, K are the least in the given ratios.

But now let E *not* measure I.

A, 6. B, 5. C, 4. D, 3. E, 2. F, 7.
H, 24. G, 20. I, 15.
M, 48. L, 40. K, 30. N, 105.
O — P — Q — R —

Having then found the least number K, which E and I measure, [Margin: i, *Elements* VII.36] let G measure L, and H measure M, as many times as I measures K; and let F measure N as many times as E measures K. I say that M, L, K, N are the least in the given ratios. For since H, G, I measure M, L, K equally, it will be, as above, that as H is to G, so M is to L; and as G is to I, so L is to K. But it is by the same reasoning that as H is to G, so A is to B, and as G is to I, so C is to D — since A, B measure H, G, and C, D measure G, I, equally. Therefore as A is to B, so M is to L; and as C is to D, so L is to K. And as E is to F, so too is K to N, since E and F measure K and N equally. M, L, K, N are therefore in continued proportion in the

given ratios. I say further that they are the least in the same ratios. For if they are not the least, let there be assigned smaller numbers than they in the same ratios, O, P, Q, R, if possible. Since A, B are the least in their ratio, they will measure O, P equally, these being in the same ratio — namely B, the consequent, measuring the consequent P. [Margin: k, *Elements* VII.21] By the same argument C, D will measure P, Q equally, namely the antecedent C measuring the antecedent P; and so, since B and C both measure P, [Margin: l, *Elements* VII.37] G, the least number that B and C measure, will also measure that same P. Now since it has been shown that as G is to I, so L is to K, that is, so P is to Q, it will be, by alternation, that as G is to P, so I is to Q; and therefore, since G measures P, I too will measure Q. But E also measures that same Q, [Margin: m, *Elements* VII.21] because E and F, the least in their ratio, measure Q, R — of the same ratio — equally, namely the antecedent E measuring the antecedent Q. Therefore, since I and E measure Q, K too — which I and E measure as their least — will measure that same Q, [Margin: n, *Elements* VII.37] the greater measuring the smaller. Which is absurd. There will therefore be given no other numbers in continued proportion in the given ratios smaller than M, L, K, N; and consequently M, L, K, N themselves are the least.

And if four ratios are given, one must first find numbers in continued proportion in the three former ratios, and then proceed with the fourth, later, ratio as we have just done with the third given ratio.

A, 6. B, 5. C, 4. D, 3. E, 2. F, 7. S, 3. T, 2.
M, 48. L, 50. [recte: 40] K, 30. N, 105. O, 70.

For example, if the fourth given ratio is in the least numbers S to T, we shall first find M, L, K, N, the least numbers in continued proportion in the three ratios A to B, C to D, and E to F. Then, if S measures N, we shall take O, which T measures as many times as S measures N; for M, L, K, N, O will then be in continued proportion...

[Continuation of Book VIII, Prop. 4 (PROBL.), from the preceding page — its final clauses, then the Scholium.]

are the least in continued proportion in the given ratios. But if S does not measure N, [Margin: c — *Elem.* VII.36] we take O, the least number that both S and N measure. Then, as many times as N measures O, let K measure P, and L measure Q, and M measure R the same number of times; and

A, 6. B, 5. C, 4. D, 3. E, 2. F, 7. S, 9. T, 2.
M, 48. L, 40. K, 30. N, 105.
R, 144. Q, 120. P, 90. O, 315. V, 70.

as many times as S measures that same O, let T measure V. Once this is done, R, Q, P, O, V will be the least numbers in continued proportion in the ratios A to B, C to D, E to F, and S to T. All of this we will prove by the same argument as before. We will proceed in the same way if five or more ratios are given in least numbers. And so, given any number of ratios whatever in least numbers, etc. Which was to be done.

SCHOLIVM

If all the given ratios, or some of them, are given in numbers that are not the least, we will nonetheless solve the proposed problem; but the given ratios must first be exhibited in their least numbers before we undertake to find the least numbers in continued proportion, as is clear from the demonstration.

This problem differs, moreover, from the one demonstrated in Proposition 35 of Book 7, in that here the numbers are not given in continued proportion — such that each intermediate one is both an antecedent and a consequent — even though the ratios are different, exactly as they are there.

Furthermore, once the least numbers in continued proportion in the given ratios have been found, if they are multiplied by any one and the same number, others will be produced in continued proportion in the same ratios, as is established from what we demonstrated at Proposition 18 of Book 7.

THEOR. 3. PROPOS. 5.

[Margin: v.]

Plane numbers have to one another a ratio compounded of their sides.

Let A and B be two plane numbers, the sides of the first being any C, D, and those of the second E, F. I say that the ratio of A to B is compounded of the ratios of the sides — namely of the ratios C to E and D to F, or of the ratios C to F and D to E — in such a way that the sides of the one are antecedents and those of the other consequents, just as we taught in Proposition 23 of Book 6. Let D and E, multiplying each other, make the number G. Since, then, D multiplying C and E made A and G, it follows [Margin: a — Elem. VII.17] that A is to G as C is to E. And in the same way, since E multiplying D and F made G and B, G is to B as D is to F. Therefore A, G, B are in continued proportion in the ratios of the sides C to E and D to F. Now the ratio of A to B is compounded of the ratios A to G and G to B [Margin: b — Elem. def. 27 [?]]. Therefore the same ratio of A to B is compounded of the ratios of the sides C to E and D to F.

A, 24. B, 48.

G, 18.

C, 4. D, 6. E, 3. F, 16.

By the same argument we will show that the ratio of A to B is compounded of the ratios C to F and D to E, if the sides E and F change places and G is made by the mutual multiplication of D and F. For since D, multiplying C and F, makes A and G, it follows [Margin: c — Elem. VII.17] that A is to G as C is to F. Similarly, since F, multiplying D and E, makes G and B, G is to B as D is to E. And so again A, G, B are in continued proportion in the ratios of the sides C to F and D to E. Since, then, the ratio of A to B is compounded of the ratios A to G and G to B, [Margin: d — Elem. def. 27 [?]] it will likewise be compounded of the ratios C to F and D to E.

Therefore plane numbers have to one another a ratio compounded of their sides. Which was to be demonstrated.

A, 24. B, 48.

G, 96.

C, 4. D, 6. F, 16. E, 3.

THEOR. 4. PROPOS. 6.

[Margin: vi.]

If there be any number of numbers in continued proportion, and the first does not measure the second, then neither will any other measure any other.

Let A, B, C, D, E be in continued proportion, and let A, the first, not measure B, the second. I say that no one of them measures any other. That none measures the one immediately following it is evident. For since A is to B as B is to C, C to D, and D to E, while A does not measure B, neither will B measure C, nor C measure D, nor D measure E. That no other of them measures any other we will show as follows. Take the three least numbers F, G, H in the ratio of A to B; [Margin: a — Elem. VIII.2] then, *ex aequali*, A will be to C as F is to H. And since A is to B as F is to G, while A does not measure B, neither does F measure G; and for this reason F will not be a unit — for otherwise F would measure G, since a unit measures every number. Therefore, since F and H are prime to one another [Margin: b — Elem. VIII.3] and F is not a unit, F will not measure H; and on that account neither will A measure C — for it was shown that A is to C as F is to H. By the same reasoning we will show that neither does B measure the third number from it, D, nor C the third, E. And if four least numbers be taken in the ratio of A to B, we will show in like manner that neither does A measure the fourth, D, nor B the

fourth, E. And so on for the rest. If, therefore, there be any number of numbers in continued proportion, etc. Which was to be shown.

A, 16. B, 24. C, 36. D, 54. E, 81.
F, 4. G, 6. G, 9. [recte: H, 9]

SCHOLIVM

If greater numbers be referred to smaller, this proposition may be stated in this manner:

If there be any number of numbers in continued proportion, and the first is not a multiple of the second, then neither will any other be a multiple of any other.

For let A, B, C, D, E be in continued proportion, and let A, the first, not be a multiple of the second, B. I say that no one of them is a multiple of any other. That none is a multiple of the one immediately following it is established. For since A is to B as B is to C, C to D, and D to E, while A is not a multiple of B, neither will B be a multiple of C, nor C of D, nor D of E. And that none of them is a multiple of any other will be confirmed thus. Since D is not a multiple of E, conversely E will not measure D, by what we wrote in Definition 5 of Book 7. Since, then, E, D, C, B, A are numbers in continued proportion — (for since D is to E as C is to D, B to C, and A to B, it follows by conversion that E is to D as D is to C, C to B, and B to A) — and E, the first, does not measure D, the second, [Margin: c — Elem. VIII.6] neither will any other of them measure any other. Therefore, conversely, if greater numbers be referred to smaller, none of them will be a multiple of any other, by what we wrote in the definitions of Book 7. But from these considerations we will also demonstrate the following theorem.

A, 81. B, 54. C, 36. D, 24. E, 16.

If there be any number of numbers in continued proportion, and the first measures the second, then any one whatever will measure any of those following it. And if the first is a multiple of the second, then any one whatever will be a multiple of any of those following it.

Let A, B, C, D, E be in continued proportion, and let the first, A, measure the second, B. I say that each of them measures any of those following it. That each measures the one immediately following it is clear. For since A is to B as B is to C, and D to E, and A measures B, then B will measure C, C measure D, and D measure E. And that any of them measures any of those following it — namely that B measures D and E — will be shown thus. Since B measures C, and C measures D, [Margin: d — 11. pro.

[?]] B will also measure D. Again, since D measures E, [Margin: e — 11. pro. [?]] B (which measures D) will also measure that same E. And so for the rest.

A, 3. B, 6. C, 12. D, 24. E, 48.

But now let the first, A, be a multiple of the second, B. I say that each of them is a multiple of any of those following it. For since A is to B as B is to C, C to D, and D to E, while A is a multiple of B, then B will be a multiple of C, C of D, and D of E.

Therefore each is a multiple of the one immediately following it. Again, since D is a multiple of E, conversely E will measure D; but by the inverse ratio E, D, C, B, A are in continued proportion. Therefore each of them will measure any of those following it, as was demonstrated; and on that account, conversely, if greater be referred to smaller, each will be a multiple of any of those following it.

A, 48. B, 24. C, 12. D, 6. E, 3.

We will also convert this sixth proposition, and the theorem which we demonstrated in the first place in the scholium, in this way:

If there be any number of numbers in continued proportion, and the first — or any other — measures none of those reckoned from the second onward, then neither will the first measure the second. And if the first, or any other, is a multiple of none of those from the second onward, then neither will the first be a multiple of the second.

Let A, B, C, D, E be in continued proportion, and let the first, A, or any other, measure none of the numbers reckoned from the second, B. I say that A, the first, does not measure B, the second. For if A, the first, be said to measure the second, B, then it would also measure — by what we showed in the second place in this scholium — any one whatever of those following. Which is absurd, since neither the first nor any other is supposed to measure any number from the second. Therefore A does not measure B.

A, 16. B, 24. C, 36. D, 54. E, 81.

Now let A, the first, or any other, not be a multiple of any number reckoned from the second, B. I say that A, the first, is not a multiple of B, the second. For if A, the first, be said to be a multiple of B, the second, then it would also be a multiple of any one whatever of those following, from what we demonstrated in the second theorem of this scholium. Which is absurd. For neither the first nor any other is supposed to be a multiple of any number from the second. Therefore A will not be a multiple of B.

A, 81. B, 45. [recte: 54] C, 36. D, 24. E, 16.

THEOR. 5. PROPOS. 7.

[Margin: vii.]

If there be any number of numbers in continued proportion, and the first measures the last, it will also measure the second.

Let A, B, C, D, E be in continued proportion, and let A, the first, measure the last, E. I say that A, the first, also measures B, the second. For if A be said not to measure B, [Margin: a — Elem. VIII.6] then neither will any other measure any; and so A will not measure E either. Which is absurd, for A is supposed to measure E. Therefore A, the first, will measure B, the second; and accordingly, if there be any number of numbers in continued proportion, etc. Which was to be demonstrated.

A, 3. B, 6. C, 12. D, 24. E, 48.

SCHOLIVM

In order to convert the theorem which we demonstrated in the second place in the scholium of the preceding proposition, we will amplify this proposition in the following way:

If there be any number of numbers in continued proportion, and the first — or any other — measures any number reckoned from the second, then the first will also measure the second. And if the first, or any other, is a multiple of any number from the second, then the first will also be a multiple of the second.

Which we will demonstrate in the same way. For if the first be said not to measure the second, or not to be a multiple of it, then neither will any other measure any, nor be a multiple of it, by Proposition 9 and the first theorem of the preceding scholium. Which is contrary to the hypothesis.

THEOR. 6. PROPOS. 8.

[Margin: viii.]

If between two numbers there fall numbers as means in continued proportion, then as many numbers as fall between them as means in continued proportion, so many will also fall as means in continued proportion between others having the same ratio with them.

Let there fall between two numbers A and B the mean proportionals C, D in continued proportion, and let E be to F as A is to B. I say that as many mean proportionals fall in continued proportion between E and F as fall between A and B. For, taking as many least numbers G, H, I, K in the ratio of A to C as there are numbers A, C, D, B, then *ex aequali* A will be to B — and therefore E to F — as G is to K.

A, 24. C, 36. D, 54. B, 81.
 G, 8. H, 12. I, 18. K, 27.
 E, 32. L, 48. M, 72. F, 108.

A, 40. C, 20. D, 10. B, 5.
 G, 8. H, 4. I, 2. K, 1.
 E, 8. L, 4. M, 2. F, 1.

A, 27. C, 9. D, 3. B, 1.
 G, 27. H, 9. I, 3. K, 1.
 E, 108. L, 36. M, 12. F, 4.

Therefore, since G and K are prime to one another, being the extremes of the least numbers, [Margin: a — Elem. VIII.3] and on that account the least in their ratio, [Margin: b — Elem. VII.23] G will equally measure E, and K will equally measure F. [Margin: c — Elem. VII.21] As many times, then, as G and K measure E and F, so many times let H and I measure the other numbers L and M, so that the numbers G, H, I, K measure the numbers E, L, M, F equally, each its own. [Margin: d — 9. pro. [?]] Since, then, G, H, I, K, multiplying the number by which they measure the numbers E, L, M, F, produce E, L, M, F themselves, E, L, M, F will be in the same ratios as G, H, I, K, as we demonstrated at Proposition 18 of Book 7. But G, H, I, K are in continued proportion. Therefore E, L, M, F are also in continued proportion; and accordingly, since the multitude of E, L, M, F equals the multitude of A, C, D, B, as many mean proportionals fall between E and F as between A and B. If, therefore, between two numbers there fall means in continued proportion, etc. Which was to be demonstrated.

SCHOLIVM

It is established, not only from the demonstration, that as many mean proportionals fall between E and F as between A and B, but also that the ratio of the numbers E, L, M, F is the same as that of the numbers A, C, D, B. For it was shown that E, L, M, F are in the same ratio as G, H, I, K; but these have, by construction, the same ratio as A, C, D, B. Therefore E, L, M, F also have the same ratio as A, C, D, B.

This same proposition is true if, A and B being numbers, either E or F be taken as a unit; likewise if either A or B be a unit while E and F are numbers, as appears in the examples.

It is also established from this theorem that between numbers in double ratio, or in any superparticular ratio, or in a superbipartient ratio, no mean proportional number can fall. For since the double ratio is found, in least numbers, between two and a unit; the superparticular between numbers differing by a unit only; and the superbipartient, finally, between numbers whose difference is two — if a mean proportional number could fall between two numbers in double, or superparticular, or superbipartient ratio, then, by this theorem, some mean proportional number would also fall between two and a unit, or between numbers differing by a unit only, or by two — namely between the least numbers that have the same ratios as those — which can in no way happen. For between two and a unit no number is interposed at all — far from their admitting any mean proportional; and likewise between two numbers distant from one another by two, only one number is inserted, which differs from each by a unit. That this can in no way be a mean proportional between them we will demonstrate in the following manner. Let the numbers AB, CD (whether CD be a unit and AB three, or not) differ by two, and let there fall between them a number EF, less than AB by a unit and greater than CD, also by a unit. I say that EF is not a mean proportional between AB and CD. For if it be said that AB is to FE as FE is to CD, then, when there is taken away from AB a number AG equal to EF itself, so that the remainder is the unit GB; and

[Dotted lettered number-segments (the magnitudes AB, EF, CD with the points G, H marked), printed in the margin beside this demonstration — two schematics side by side:]

A . . G . B A G . B
 E . H . F E H . F
 C . D C D

[Book VIII — continued]

Scholium to Proposition 8 (continued)

The demonstration of the preceding proposition concludes. The numbers under discussion are shown as lettered dotted number-segments, at two scales:

A . . G . B A G . B
 E . H . F E H . F
 C . D C D

GB; and from EF let the number EH, equal to CD, be taken away, so that the unit HF is likewise left over. Then, as the whole AB is to the whole EF, so too will the part removed, AG, be to the part removed, EH — since AG and EH are, by construction, equal to EF and CD respectively. Therefore the remainder GB will also stand to the remainder HF — that is, a unit to a unit — as the whole AB stands to the whole EF, the greater to the less. But this is absurd. Therefore EF is not a mean proportional between AB and CD.

And so no mean proportional can fall between numbers in triple ratio. Otherwise, by this same theorem, a mean proportional would also fall between 3 and 1, the least numbers of the triple ratio, which differ from one another by two — and we have just now shown that this cannot happen.

By the same reasoning, no mean proportional can fall between numbers in quintuple ratio. For suppose one is said to fall; then, by this same theorem, a mean proportional will also fall between 5 and 1, the least numbers of the quintuple ratio. That this is impossible we shall demonstrate as follows. First, let there fall — if it is possible — between the number five, AB, and the unit C, a mean proportional, either the number two or the number three, D, such that AB is to D as D is to C; and, conversely, C is to D as D is to AB.

A B . E
D . . D . . .
C .

[Margin: a — 11.pron. (Axiom 11)]

Now since the unit C measures D, D will in turn measure AB. But two or three, D, also measures six, AE. Therefore D measures the whole AE and the part removed AB; and consequently D, a number, will measure the remaining unit BE. Which is absurd.

Next, let there fall — if it is possible — between the number five, AB, and the unit C, the mean proportional four, D. We shall show, as before, that D measures the number five, AB. But four, D, also measures four, AE. Therefore D measures the whole AB and the part removed AE; and consequently D, a number, will measure the remaining unit EB. Which is absurd.

A E . B
D
C .

[Margin: b — 11.pron. (Axiom 11)]

From these facts it follows that neither the musical interval consisting in the double ratio — the *Diapason* [Greek: διαπασῶν (*diapasōn*, the octave)], or as it is commonly called, the eighth — nor the interval found in the sesquioctave ratio [9:8] — namely the *Tonus* (the whole tone, or in common speech the second) — can be bisected, that is, divided into two equal ratios. For a ratio is said to be bisected (so far as our purpose requires) when a mean proportional falls between its terms. Thus, because between the terms 24 and 6, which are in quadruple ratio, there falls the mean proportional number 12 — in this manner, 24. 12. 6 — the quadruple ratio is said to be divided into two double ratios. Since, then, it has been shown that no mean proportional number falls between numbers in double ratio or in a superparticular ratio [*ratio superparticularis*] such as the sesquioctave, it is plain that the octave and the whole tone cannot be bisected. Hence the octave, in its first division into the *Diapente* [Greek: διαπέντε (*diapente*, the fifth)] and the *Diatessaron* [Greek: διατεσσάρων (*diatessarōn*, the fourth)] — of which intervals the former consists in the sesquialterate ratio [3:2], the latter in the sesquitercian [4:3] — is divided by the musicians, as appears here, 2. 3. 4. For here the double ratio is divided into the sesquialterate and the sesquitercian, as into its greatest parts unequal to one another. In the same way the whole tone is customarily divided into two semitones, of which one is called the greater, the other the less. But you will find more on these matters among the writers on music.

Again, from these results it can be demonstrated that the ratio of the diagonal of any square to its side cannot be expressed in numbers, but is irrational. For since (as we demonstrated at Prop. 47 of Book I) the square on the diagonal is double the square described on the side, while the ratio of the squares is the duplicate of the ratio of the sides, it follows that the ratio of the square described on the diagonal to the square on the side is the duplicate of the ratio of the diagonal to the side. Since, then, that ratio whose duplicate is the double ratio cannot be expressed in numbers — because, as we have shown, no mean proportional falls between numbers in double ratio to bisect it — it is manifest that the ratio of the diagonal to the side cannot be expressed in numbers either, but is irrational; or, what is the same thing, that the diagonal is incommensurable with the side. On this matter we shall write more at Prop. 9 and the last proposition of Book X.

[Margin: ix.]

THEOR. 7. PROPOS. 9.

If two numbers are prime to one another, and between them numbers fall in continued proportion, then however many numbers fall in

continued proportion between them, just so many will fall in continued proportion between each of them and a unit.

Let the mean proportionals C, D fall in continued proportion between the numbers A and B, which are prime to one another. I say that just as many continued proportionals fall between the unit and A, and likewise between the unit and B, as fall between A and B. For let two numbers E and F be found, the least in the ratio of A to C [Margin: a — 2.oct. = Elements VIII.2]; and in the same proportion let there be taken the least three, G, H, I, and the least four, K, L, M, N, and so on, until the multitude of those taken equals the multitude of A, C, D, B.

A, 8. C, 12. D, 18. B, 27.

Vnitas.

1.

E, 2. F, 3.

G, 4. H, 6. I, 9.

K, 8. L, 12. M, 18. N, 27.

Now since A and B, the extremes, are prime to one another [Margin: b — 1.oct. = Elements VIII.1], A, C, D, B will be the least numbers in the ratio of E to F. But K, L, M, N are likewise just as many and, by construction, the least in the same ratio. Therefore K, L, M, N are severally equal to A, C, D, B — K to A and N to B [Margin: c — 1.pron. = Axiom 1] — lest numbers less than the least be assigned. And since, as is clear from the demonstration of Prop. 2 of this book, E multiplied by itself produced G, and multiplying G made K, E measures G by E [Margin: d — 5.pron. = Axiom 5]; but the unit also measures E by E. Equally, then, the unit measures E, E measures G, and G measures K; and therefore the unit is the same part of E that E is of G, and G is of K. So the unit and the numbers E, G, K are, one after another, proportional [Margin: e — 20.def. = Elements VII, def. 20]. By the same reasoning — since it is likewise manifest from the demonstration of Prop. 2 of this book that F multiplied by itself produces I, and multiplying I makes N — F measures I by F, and I measures N by the same F [Margin: f — 7.pron. = Axiom 7]; but the unit also measures F by F [Margin: g — 5.pron. = Axiom 5]. Equally, then, the unit measures F, F measures I, and I measures N; and therefore the unit is the same part of F that F is of I, and I is of N.

So the unit and the numbers F, I, N are, one after another, proportional [Margin: c — 20.defin. = Elements VII, def. 20]. And accordingly, since the multitude E, G, K, as well as F, I, N, together with the unit, equals the multitude K, L, M, N (or A, C, D, B) — as is clear from Prop. 2 of this book, for E and F are the second terms from the unit, G, H, I the third, K, L, M, N the fourth, and so on —

A, 8. C, 12. D, 18. B, 27.

Vnitas.

1.

E, 2. F, 3.

G, 4. H, 6. I, 9.

K, 8. L, 12. M, 18. M, 27.

[recte: the final term should read N, 27; the compositor here prints "M, 27." On the identical array of the previous page it correctly reads N, 27.]

just so many mean proportional numbers in continued proportion will fall between the unit and K (that is, A, its equal), and between the unit and the number N (that is, B, its equal), as fall between the numbers A and B. Therefore, if two numbers are prime to one another and mean proportionals fall between them, and so on. Which was to be shown.

SCHOLIUM

It is evident that the numbers which fall in continued proportion between the numbers A and B and the unit have their ratios named after the least numbers of the ratio of A to C — that is, the ratios which the numbers E and F bear to the unit — as we also asserted in the scholium to Prop. 2 of this book.

It is likewise established from this demonstration that, if a number multiplying itself makes some number and then multiplies the product, and so on in turn, all the products are in continued proportion from the unit. For it has been shown, from the demonstration of Prop. 2 of this book, that E, G, K and F, I, N, generated in this way, are in continued proportion from the unit.

[Margin: x.]

THEOR. 8. PROPOS. 10.

If between two numbers and a unit numbers fall in continued proportion, then however many numbers fall in continued proportion between each of the two and the unit, just so many will fall in continued proportion between the two numbers themselves.

Let there fall, between each of the numbers A, B and the unit, any number of continued proportionals: between A and the unit the numbers C, D, E; and between B and the unit the numbers F, G, H, equal in multitude to the former. I say that just as many mean proportionals in continued proportion fall between A and B as fall between each of A, B and the unit. For let C and F, multiplied into one another, make I. Then let C, multiplying I and G, make K and L. Again let the

same C, multiplying K, L, and H, make M, N, and O — just as many between A and B as there are between each of A, B and the unit.

A, 81. M, 162. N, 324. O, 648. B, 1296.

D, 9. I, 18. G, 36.

C, 3. F, 6.

1.

vnitas.

Now since, as the unit is to C, so is C to D, D to E, and E to A, the unit measures C just as C measures D, D measures E, and E measures A. But the unit measures C by C [Margin: a — 5.pron. = Axiom 5]; therefore C also measures D, D measures E, and E measures A, all by C [Margin: b — 9.pron. = Axiom 9]. Hence C, multiplying itself, made D; multiplying D, made E; and multiplying E, made A. By the same reasoning F, multiplying itself, made G; multiplying G, made H; and multiplying H, made B. And so, since C, multiplying C and F, made D and I, then as C is to F, so is D to I [Margin: c — 17.septi. = Elements VII.17]. Similarly, since F, multiplying C and F, made I and G, then as C is to F, so is I to G [Margin: d — 17.septi. = Elements VII.17 (printed "17.sexti")]. Therefore the three numbers D, I, G are in continued proportion in the ratio of C to F. Again, since C, multiplying D, I, G, made E, K, L, the numbers E, K, L will have (by what we showed at Prop. 18 of Book VII) the same continued proportion as D, I, G — that is, the ratio of C to F. In the same way, since C and F, multiplying G, made L and H, as C is to F, so is L to H [Margin: e — 18.septi. = Elements VII.18]. So the four numbers E, K, L, H are in continued proportion in the ratio of C to F. Finally, since C, multiplying E, K, L, H, made A, M, N, O, these — by what we demonstrated at Prop. 18 of Book VII — A, M, N, O will have the same continued proportion as E, K, L, H, that is, the ratio of C to F. By the same reasoning, since C and F, multiplying H, made O and B, as C is to F, so is O to B [Margin: f — 18.septi. = Elements VII.18]. Therefore the five numbers A, M, N, O, B are in continued proportion in the ratio of C to F; and consequently just as many mean proportionals fall between A and B as fall between H (or B) and the unit, since the multitude M, N, O has been made equal to the multitude C, D, E (or F, G, H). Therefore, if between two numbers and the unit continued proportionals fall, and so on. Which was to be demonstrated.

SCHOLIUM

From these things it is established that the numbers which fall as mean proportionals between A and B have the ratio which the two numbers nearer to the unit — namely C and F — have.

It is also plain from this demonstration that, given any numbers in continued proportion from the unit, the second from the unit multiplied into itself produces the third; from the same second multiplied into this third arises the fourth; from the same into this the fifth; and so on. For it has been demonstrated, from the fact that C, D, E, A are in continued proportion from the unit, that D, the third, arises from C, the second, into itself; E from C into D; and A from the same C into E, and so on.

It is fitting here to demonstrate some other theorems pertaining to numbers in continued proportion, which will be useful both for what follows and for many other things; and we take our beginning here.

I.

If from a unit there be two series of numbers in continued proportion, equal in multitude, then the third from the unit will have to the third the duplicate of the ratio which the second from the unit has to the second; the fourth the triplicate; the fifth the quadruplicate; and always so on, each by one more.

Let A, B, C, D be in continued proportion from the unit, and let there be as many others, E, F, G, H, from the same unit. I say that the ratio of B, the third from the unit, to F, the third from the same unit, is the duplicate of the ratio which A, the second, has to E, the second, and so on. For since between each of the numbers B, F and the unit there falls a single mean proportional — between B and the unit the number A, and between F and the unit the number E [Margin: a — 10.oct. = Elements VIII.10] — one mean proportional will also fall between B and F, and indeed (by the scholium to this proposition) in the ratio of A to E.

D, 81. M, 108. N, 144. O, 192. H, 256.

C, 27. K, 36. L, 48. G, 64.

B, 9. I, 12. F, 16.

A, 3. E, 4.

1.

vnitas.

Let it fall, then, and be I. In the same way two means will fall between C and G in the same ratio of A to E, namely K and L — just as many as fall between each of C, G and the unit. And likewise three, M, N, O, in the same ratio of A to E, will fall between D and H. Since, then, by definition B has to F the duplicate of the ratio which B has to I, and as B is to I so is A to E, B will also have to F the duplicate of the ratio which A has to E. In no other way, C will have to G the triplicate of the ratio of A to E; for the ratio of C to G is the triplicate of the ratio of C to K, and as C

is to K so is A to E. So too D will have to H the quadruplicate of the ratio of A to E; and so with the rest.

We shall demonstrate this same thing if there be two series of numbers in continued proportion beginning from some one and the same number. Hence we shall state this same theorem as follows.

II.

If from some one and the same number there be two series of numbers in continued proportion, equal in multitude, then the third from that number will have to the third the duplicate of the ratio which the second from it has to the second; the fourth the triplicate; the fifth the quadruplicate; and always so on, each by one more.

Let B, C, D, E be in continued proportion from the number A, and let there be as many others, F, G, H, I, from the same A. I say again that the ratio of B to F is the duplicate of the ratio of C to G; that of D to H the triplicate; and that of E to I the quadruplicate. From A into itself let K be made; from A into K, L; and from A into L, M. Similarly from B into itself let N be made; from B into N, O; and from B into O, P. Finally from F into itself let Q be made; from F into Q, R; and from F into R, S. When this is done, A, K, L, M will be in continued proportion from the unit, as is established from the scholium to Prop. 9 of this book. By the same reasoning B, N, O, P will be proportional from the unit; and likewise F, Q, R, S.

E, 162. I, 512.

D, 54. Vnitas. H, 128.

C, 18. 1. G, 32.

B, 6. F, 8.

A, 2.

N, 36. K, 4. Q, 64.

O, 216. L, 8. R, 512.

P, 1296. M, 16. S, 4096.

Since, then, the ratio of N to K is the duplicate of the ratio of B to A, by Theorem 1 of this scholium — and, by definition, the ratio of C to A is likewise the duplicate of the same ratio of B to A — C will be to A as N to K. In the same way A will be to G as K to Q; for by the same Theorem 1, and by definition, the ratio of A to G is the duplicate. Therefore, since C is to A as N to K, and A is to G as K to Q, *ex aequali* C will be to G as N to Q. But the ratio of N to Q is the duplicate of the ratio of B to F, by Theorem 1 of this scholium — because both B, N and F, Q are in continued proportion from the unit, by the scholium to Prop. 9 of this book. Therefore the ratio of C to G is also the duplicate of the ratio of B to F. By the same arguments the ratio of D to H will be the triplicate of the ratio of B to F. For the ratio of O to L

is, by Theorem 1, the triplicate of the ratio of B to A — because both B, N, O and A, K, L are in continued proportion from the unit, by the scholium to Prop. 9 of this book — and the ratio of D to A is likewise the triplicate, by definition. Therefore D is to A as O to L.

E, 81. I, 1.
D, 54. Vnitas. H, 2.
C, 36. 1. G, 4.
B, 24. F, 8.
A, 16.
N, 576. K, 256. Q, 64.
O, 13824. L, 4096. R, 512.
P, 331776. M, 65536. S, 4096.

In the same way A is to H as L to R, since each ratio is the triplicate of the ratio of A to F: the ratio of A to H by definition, and the ratio of L to R by Theorem 1 of this scholium, because both A, K, L and F, Q, R are in continued proportion from the unit, by the scholium to Prop. 9 of this book. Therefore *ex aequali* D is to H as O to R. But the ratio of O to R is the triplicate of the ratio of B to F, by Theorem 1, because both B, N, O and F, Q, R are in continued proportion from the unit, by the scholium to Prop. 9 of this book. Therefore the ratio of D to H is also the triplicate of the same ratio of B to F. In no different way shall we demonstrate that the ratio of E to I is the quadruplicate of the ratio of B to F. And so on.

Euclid, *Elements* — Book VIII (Clavius's commentary)

[Continuation of the scholium on duplicate, triplicate, and quadruplicate ratios begun in the preceding pages.]

The very same thing will be demonstrated if the numbers of one series terminate in a unit, as is clear from the second figure, in which I is the unit.

Moreover, we shall demonstrate this theorem also for lines proportional from one and the same line (Book 14, prop. 28), though not for any number of lines whatever. Hence it holds far more generally for numbers than it does for lines. And from what has thus been demonstrated we shall make this proposition 10 of Euclid more universal, in the following way.

III.

If between two numbers and some other assumed number there fall numbers in continued proportion, then as many means in continued

proportion as fall between each of the two and the assumed number, just so many will also fall as means in continued proportion between the two numbers themselves.

Between each of the numbers A and B and the assumed number C let any quantity of continued proportionals fall: between A and C the numbers D, E, F; and between B and C the same quantity of terms, G, H, I. I say that as many means in continued proportion fall between A and B as fall between A and C and between B and C; likewise, that as many fall between F and I as fall between F and C and between I and C; and as many between E and H as between E and C and between H and C. For take three numbers K, L, M, the least in the ratio of D to G; then by definition:

A, 162. Q, 216. R, 288. S, 384. B, 512.
F, 54. O, 72. P, 96. I, 128.
E, 18. N, 24. H, 32.
D, 6. G, 8.
C, 2.
K, 9. L, 12. M, 16.

the ratio of K to M is the duplicate of the ratio K to L, that is, of D to G. But by theorem 2 of this scholium the ratio of E to H is likewise the duplicate of that same ratio, D to G. Therefore as K is to M, so is E to H; and so, since one mean falls between K and M — namely N — one mean also falls between E and H, just as one falls between E and C and between H and C.[Margin: (a) Elements VIII.8] In the same way, if four least numbers are taken in the same ratio, D to G, we shall show that two means fall between F and I, just as two means fall between F and C and between I and C. And by the same reasoning three means will fall between A and B, if five least numbers are taken in the same ratio, D to G.

This holds also if, in place of one of the numbers — namely B — a unit is assumed, as is plain in this second figure, in which the number B is a unit, and there fall between A and C, as well as between B and C, three numbers in continued proportion — that is, as many as fall between A and B, and so on.

A, 1048576. Q, 32768. R, 1024. S, 32. B, 1.
F, 65536. O, 2048. P, 64. I, 2.
E, 4096. N, 128. H, 4.
D, 256. G, 8.
C, 16.
K, 1024. L, 32. M, 1.

From these things it is also apparent that the numbers which fall as mean proportionals between A and B — and likewise between F and I, and between E

and H — bear a ratio nearer to the assumed number C than the two numbers D and G do.

THEOR. 9. PROPOS. 11. [Margin: xj.]

Between two square numbers there is one mean proportional number;
and a square has to a square the duplicate ratio of side to side.

Let A and B be square numbers, whose sides are C and D. I say that one mean proportional number falls between A and B, and that the ratio of A to B, square to square, is the duplicate of the ratio C to D, side to side. For let C and D, multiplied by one another, make E. Since, then, C multiplying itself made the square A (by the definition of a square), and multiplying D made E (by the construction), [Margin: (a) Elements VII.17] it will be as C is to D, so A to E. Again, since D multiplying C made E (by the construction), and multiplying itself made the square B (by the definition of a square), [Margin: (b) Elements VII.17] it will likewise be as C is to D, so E to B. Therefore A, E, B are continued proportionals in the ratio of the sides C and D; and accordingly the mean E falls in continued proportion between the squares A and B.

A, 9. E, 21. B, 49. C, 3. D, 7.

Now since, from the fact that A, E, B are continued proportionals, the number A has to B the duplicate of the ratio it has to E, the square A will also have to the square B the duplicate of the ratio which the side C has to the side D — since this ratio is the same as that of A to E. Therefore between two square numbers there is one mean proportional, and so on. Which was to be demonstrated.

SCHOLIVM.

It is clear from what has been said that between two square numbers there falls a mean proportional number, in the continued proportion of side to side. For the ratio of the square A to the mean proportional E is the same as that of the side C to the side D, as has been demonstrated.

EVCLID. GEOM. — Book VIII (continued)

By the same reasoning it is evident that the mean proportional E and each of the squares A, B are composite with respect to one another [i.e. share a common measure]. For since A, E, B have been shown to be proportional in the ratio C to D — that is, since A is to E, and E to B, as C to D — and since the side D measures its own square B, the consequent measuring the consequent (if we speak of the ratios E to B and C to D), C will also measure E, the antecedent measuring the

antecedent, seeing that E is to B as C is to D. But the side C also measures its own square A. Therefore E and A have C as a common measure, and so are composite with respect to one another. Similarly, since A is to E as C to D, and the side C measures its own square A, the antecedent measuring the antecedent, D will also measure E, the consequent measuring the consequent. And since the side D also measures its own square B, E and B will have D as a common measure, and so will be composite with respect to one another. It is moreover clear from this demonstration that the common measure of the prior numbers A, E is C, the side of the prior square A; while the common measure of the posterior numbers E, B is D, the side of the posterior square B.

THEOR. 10. PROPOS. 12. [Margin: xj.]

Between two cube numbers there are two mean proportional numbers;
and a cube has to a cube the triplicate ratio of side to side.

Let A and B be cube numbers, whose sides are C and D. I say that two mean numbers fall between A and B in continued proportion, and that the ratio of A to B, cube to cube, is the triplicate of the ratio C to D, side to side. For let C multiplying itself make E; let D multiplying itself make F; let C and D multiplying one another make G; and let G, multiplied [by C and by D], make H and I. Since, then, C multiplying itself and D made E and G, [Margin: (a) Elements VII.17] it will be as C is to D, so E to G. By the same reasoning, since D multiplying C and itself made G and F, [Margin: (b) Elements VII.17] it will likewise be as C is to D, so G to F; and therefore E, G, F are continued proportionals in the ratio C to D. Again, since (by the definition of a cube) C multiplying E made A, and (by the construction) multiplying G made H, [Margin: (c) Elements VII.17] it will be as E is to G — that is, as C to D — so A to H. Similarly, since D (by the construction) multiplying G made the number I, and multiplying F (by the definition of a cube) made the cube B, [Margin: (d) Elements VII.17] it will likewise be as G is to F — that is, as C to D — so I to B. And H is to I as C is to D, [Margin: (e) Elements VII.18] because C and D, multiplying G, made H and I by the construction. Therefore A, H, I, B are continued proportionals in the ratio C to D; and accordingly the two means H and I fall between the cubes A and B in continued proportion. Now since, from the fact that A, H, I, B are continued proportionals, the number A has to B the triplicate of the ratio it has to H, the cube A will also have to the cube B the triplicate of the ratio which the side C has to the side D — since C is to D as A is to H. For this reason, between two cube numbers there are two mean proportionals, and so on. Which was to be shown.

A, 27. H, 36. I, 48. B, 64.
E, 9. G, 12. F, 16.
C, 3. D, 4.

SCHOLIVM.

Here too it is manifest that between two cubes there fall two mean proportional numbers in the continued proportion of side to side. For it has been shown that A is to H, and H to I, and I to B, as C is to D.

In the same way it is established that the two mean proportionals H, I and each of the cubes A, B are composite with respect to one another. For since A, H, I, B have been shown to be proportional in the ratio C to D — that is, since A is to H, and I to B, as C to D — and since the side D measures its own cube B, the consequent measuring the consequent (if we speak of the ratios I to B and C to D), C will also measure I, the antecedent measuring the antecedent, seeing that I is to B as C is to D. But the side C measures its own cube A as well; indeed it also measures H, since H was made by the multiplication of C into G, by the construction. Therefore A, H, I have C as a common measure, and so are composite with respect to one another. Similarly, since A is to H as C to D, and the side C measures its own cube A, the antecedent measuring the antecedent, D will also measure H, the consequent measuring the consequent. And since the side D measures its own cube B — indeed also I, since I was made by the multiplication of D into G, by the construction — H, I, B have D as a common measure; and accordingly they are composite with respect to one another. It is moreover manifest here too that the common measure of the prior three numbers A, H, I is C, the side of the prior cube A; while the common measure of the posterior three, H, I, B, is D, the side of the posterior cube E [recte: B?].

A, 27. H, 36. I, 48. B, 64.
E, 9. G, 12. F, 16.
C, 3. D, 4.

THEOR. 11. PROPOS. 13. [Margin: xij.]

If there be any number of numbers in continued proportion, and each, multiplying itself, produces certain numbers, those produced from them will be proportional; and if the numbers first set down, multiplying those already made, produce certain numbers, these too will be proportional; and this always happens with respect to the extremes.

Let A, B, C be continued proportionals, which multiplying themselves make D, E, F; and let these multiplying D, E, F make G, H, I; and again, multiplying G, H, I,

make K, L, M, and so on in succession. I say that D, E, F, and G, H, I, and K, L, M are likewise continued proportionals. For let A and B, multiplying one another, make N; and let B and C, multiplying one another, make O. Then let A, multiplying N and E, make P and Q. Likewise let B, multiplying O and F, make R and S. In the same way let A, multiplying P, Q, H, make T, V, X; and let B, multiplying R, S, I, make Y, Z, a. [Margin: (a) Elements VII.17] Since, then, A multiplying itself and B made D and N, it will be as A is to B, so D to N. In the same way, since B multiplying A and itself made

LIBER VIII. (continued)

N and E, it will also be as A is to B, so N to E. Therefore D, N, E are continued proportionals in the ratio A to B. Again, since B multiplying itself and the number C made E and O, [Margin: (b) Elements VII.17] it will be as B is to C, so E to O. And by the same

A, 2. B, 4. C, 8.

D, 4. N, 8. E, 16. O, 32. F, 64.

G, 8. P, 16. Q, 32. H, 64. R, 128.

K, 16. T, 32. V, 64. X, 128. L, 256. Y, 512. Z, 1024. a, 2048. M, 4096.

reasoning, since C multiplying B and itself made O and F, it will be as B is to C, so O to F; and therefore E, O, F too are continued proportionals in the ratio B to C, or A to B. And so, since D, N, E are continued proportionals in the same ratio as E, O, F, it will be, *ex aequali*, that D is to E as E is to F; and accordingly D, E, F are continued proportionals.

Next, since A multiplying D, N, E made G, P, Q, then — from what we showed at proposition 18 of Book 7 [Margin: (c) Elements VII.18] — G, P, Q will be proportional in the same ratio as D, N, E, that is, in the ratio A to B. Likewise, since A and B multiplying E made Q and H, it will also be as A is to B, so Q to H. Therefore G, P, Q, H are proportional in the ratio A to B. Similarly, since B multiplying E, O, F made H, R, S, then — from what was demonstrated at proposition 18 of Book 7 — H, R, S will be proportional in the ratio E, O, F, that is, B to C, or A to B. And in the same way, since B and C multiplying F made S and I, [Margin: (d) Elements VII.18] it will be as B is to C — that is, as A to B — so S to I; and therefore H, R, S, I too are proportional in the ratio A to B. For which reason, since G, P, Q, H have the same continued proportion as H, R, S, I, it will be, *ex aequali*, that G is to H as H is to I; and accordingly G, H, I are continued proportionals.

By an argument not unlike this we shall demonstrate that K, L, M too are continued proportionals; and we shall proceed in the same way in the remaining cases. Therefore, if there be any number of numbers in continued proportion, and each multiplying itself, and so on. Which was to be shown.

SCHOLIUM.

Now it is clear from the demonstration that the numbers produced in the first place, D, E, F, are proportional in the duplicate ratio of the given numbers A, B, C. For D has to E the duplicate of the ratio it has to N, that is, of A to B, and so on.

Likewise the numbers begotten in the second place, G, H, I, will be in the triplicate ratio of A to B; and those produced in the third place in the quadruplicate ratio; and so onward, always one degree higher.

We shall demonstrate the whole proposition more briefly in this way. From A, B, C, continued proportionals, multiplied into themselves, let the numbers D, E, F be made; and into these, from the same, the numbers G, H, I; and again, from the same into these, the numbers K, L, M. I say that D, E, F, and G, H, I, and K, L, M are likewise continued proportionals. For, by the scholium of proposition 9 of this book, both A, D, G, K and B, E, H, I, and C, F, I, M, are proportional from unity in continued proportion. Therefore, by theorem 1 of the scholium of proposition 10 of this book, D will be to E in the duplicate ratio of A to B, or of B to C. But of that same ratio, B to C, the ratio E to F is the duplicate, by the same theorem. Therefore D, E, F are continued proportionals in the duplicate ratio of A to B and of B to C. In the same way we shall show that G, H, I are continued proportionals in the triplicate ratio of A to B and of B to C; and K, L, M in the quadruplicate; and so with the rest.

A, 2. B, 4. C, 8.
D, 4. E, 16 [?]. F, 64.
G, 8. H, 64. I, 512.
K, 16. L, 256. M, 4096.

From this demonstration in turn it appears that the numbers produced in the first place are in the duplicate ratio of the two [given] numbers, while those begotten in the second place are in the triplicate, and so on. Which is drawn out more clearly than daylight from theorem 1 of the scholium of proposition 10 of this book.

But although in each demonstration of this proposition 13 only three continued proportionals A, B, C have been given, we shall nevertheless demonstrate the same proposition even if there be more than three. For let there be more than

three numbers in continued proportion, A, B, C, D; which multiplying themselves make E, F, G, H; and then, multiplying E, F, G, H, make I, K, L, M, and so on. Since, then, E, F, G are proportional from what has been demonstrated;[Margin: (e) Elements VIII.13] and likewise F, G, H — since the former were produced from A, B, C, proportionals, into themselves, and the latter from B, C, D, likewise proportionals, into themselves — E, F, G, H will be continued proportionals. In no other way will I, K, L, M, and the others in succession, produced in the same manner, be proportional.

A, 2. B, 4. C, 8. D, 16.

E, 4. F, 16. G, 64. H, 256.

I, 8. K, 64. L, 512. M, 4096.

THEOR. 12. PROPOS. 14. [Margin: xii.]

If a square number measures a square number, the side of the one will also measure the side of the other; and if the side of one square measures the side of the other, the square too will measure the square.

Let the square A, whose side is C, measure the square B, whose side is D. I say that the side C also measures the side D. For let C and D, multiplying one another, make E. Since, then — as is clear from the demonstration of proposition 11 of this book — A, E, B are continued proportionals in the ratio C to D, and A, the first, measures B, the last extreme,[Margin: (a) Elements VIII.7] A the first will also measure E the second. Therefore, since A is to E as C is to D, C will also measure D.

A, 4. E, 12. B, 36. C, 2. D, 6.

Now let C, the side, measure the side D. I say that the square A also measures the square B. For in the same way it will be, as C is to D, so A to E, because A, E, B are continued proportionals in the ratio C [to D], as was demonstrated at proposition 11 of this book. Therefore, since C measures D, A the first will also measure E the second, and consequently the extreme B as well, by theorem 2 of the scholium of proposition 6 of this book. Therefore, if a square number measures a square number, and so on. Which was to be shown.

THEOR. 13. PROPOS. 15.

[Margin: xiv.]

If a cube number measures a cube number, then the side of the one measures the side of the other. And if the side of one cube measures the side of the other, then the cube measures the cube.

Let cube A, whose side is C, measure cube B, whose side is D. I say that side C also measures side D. For let each of C and D, multiplying itself, make E and F respectively; let C and D, multiplying one another, make G; and finally, multiplying G, let them make H and I. Since, then — as is clear from the demonstration of Prop. 12 of this book — both E, G, F and A, H, I, B are continued proportionals in the ratio of C to D, and since A, the first term, measures B, the last, [Margin: a — 7. oct. (*Elements* VIII.7)] the same A, the first, will also measure H, the second. And since, as A is to H, so is C to D (because A, H, I, B are continued proportionals in the ratio C to D, by Prop. 12 of this book), and since A measures H, side C will also measure side D.

A, 8. H, 24. I, 72. B, 216.
 E, 4. G, 12. F, 36.
 C, 2. D, 6.

Now let side C measure side D. I say that cube A also measures cube B. For by the same argument, as C is to D, so will A be to H, because A, H, I, B are continued proportionals in the ratio C to D, as was shown at Prop. 12 of this book. Therefore, since side C measures side D, A will also measure H; and hence it will also measure the last term B — cube measuring cube — from what we demonstrated at Prop. 6 of this book. And so, if a cube number measures a cube number, and so on. Which was to be demonstrated.

THEOR. 14. PROPOS. 16.

[Margin: xv.]

If a square number does not measure a square number, then neither will the side of the one measure the side of the other. And if the side of one square does not measure the side of the other, then neither will the square measure the square.

Let A and B be squares whose sides are C and D, and let A not measure B. I say that neither does side C measure side D. For, if it be possible, let C measure D. Since, then, C, the side of square A, measures D, the side of square B, [Margin: a — 14. octa. (*Elements* VIII.14)] square A will also measure square B. But this is absurd, for it was assumed not to measure. Therefore side C does not measure side D.

A, 16. B, 81. C, 4. D, 9.

But now let side C not measure side D. I say that neither will square A measure square B. For if A be said to measure B, [Margin: b — 14. octa. (*Elements* VIII.14)]

C, the side of the former, would also measure D, the side of the latter. But this is absurd, for it was assumed not to measure. Therefore square A will not measure square B. Therefore, if a square number does not measure a square number, and so on. Which was to be shown.

THEOR. 15. PROPOS. 17.

[Margin: xv. [?] — reads xv; under the lag-1 convention xvi would be expected; see anomaly note]

If a cube number does not measure a cube number, then neither will the side of the one measure the side of the other. And if the side of one cube does not measure the side of the other, then neither will the cube measure the cube.

Let A and B be cubes whose sides are C and D, and let A not measure B. I say that neither does side C measure side D. For if C be said to measure D, [Margin: a — 15. oct. (*Elements* VIII.15)] cube A would also measure cube B. But this is absurd, since it was assumed not to measure. Therefore side C does not measure side D.

A, 8. B, 27. C, 2. D, 3.

But now let side C not measure side D. I say that neither will cube A measure cube B. For if it be said to measure, [Margin: b — 15. oct. (*Elements* VIII.15)] C, the side, would also measure the side D. But this is absurd, for it was assumed not to measure. Therefore cube A will not measure cube B. Therefore, if a cube number does not measure a cube number, and so on. Which was to be demonstrated.

SCHOLIVM.

The four immediately preceding propositions can also be stated in this way, if the greater numbers are referred to the smaller.

If a square number is a multiple of a square number, and a cube of a cube, then the side of the one will also be a multiple of the side of the other. And if the side of one is a multiple of the side of the other, then the square will be a multiple of the square, and the cube of the cube. But if the square is not a multiple of the square, nor the cube of the cube, then neither will the side be a multiple of the side. And if the side is not a multiple of the side, then neither will the square be a multiple of the square, nor the cube of the cube.

For if square A is a multiple of square B, and cube A of cube B, then B will measure A — the square measuring the square, and cube B the cube A. [Margin: c

— 14. & 15. oct. (*Elements* VIII.14 & 15)] Therefore side D will also measure the side; and consequently side C will be a multiple of side D.

A, 36. B, 9. C, 6. D, 3.

But if side C is a multiple of side D, then side D measures side C. [Margin: d — 14. & 15. oct. (*Elements* VIII.14 & 15)] Therefore B will also measure A — the square measuring the square, and the cube the cube; and consequently A will be a multiple of B — the square of the square, and the cube of the cube.

But if A is not a multiple of B — neither the square of the square, nor the cube of the cube — then B will not measure A, neither the square measuring the square nor the cube the cube. [Margin: g — 16. & 17. oct. (*Elements* VIII.16 & 17)] Therefore neither will side D measure side C. Hence C will not be a multiple of side D.

A, 64. B, 8. [B prints as "S"; read 8 — see anomaly note]
C, 4. D, 2.

A, 49. B, 9.
C, 7. D, 3.

A, 125. B, 8.
C, 5. D, 2.

Likewise, if side C is not a multiple of side D, then D will not measure the side C. [Margin: h — 16. & 17. oct. (*Elements* VIII.16 & 17)] Therefore neither will B measure A — neither the square the square, nor the cube the cube; and so A will not be a multiple of B — neither the square of the square, nor the cube of the cube.

THEOR. 16. PROPOS. 18.

[Margin: xvi. [?]]

Between two similar plane numbers there is one mean proportional number; and a plane number has to a plane the duplicate ratio of that which the corresponding side has to the corresponding side.

Let A and B be similar plane numbers; let the sides of the former be C and D, and those of the latter, proportional to them, E and F — so that C and D, multiplying one another, make A, and E and F, multiplying one another, make B, and as C is to D, so is E to F. I say that between A and B there falls one mean proportional number, and that the ratio of A to B is the duplicate of the ratio of the

corresponding sides C to E (or D to F). For let D and E, multiplying one another, make G. Since, then, C is to D as E is to F, then, alternately, C will be to E as D is to F. And because D, multiplying C and E, made A and G, [Margin: a — 17. septi. (*Elements* VII.17)] A will be to G as C is to E — that is, as D is to F. Similarly, because E, multiplying D and F, made G and B, [Margin: b — 17. septi. (*Elements* VII.17)] G will also be to B as D is to F.

A, 12. G, 18. B, 27.
C, 6. D, 2. E, 9. F, 3.

Therefore A, G, B are proportional in the ratio of C to E (or D to F); and thus G falls as a mean proportional between A and B.

Now, since A, G, B are continued proportionals, A has to B the duplicate ratio of that which A has to G — that is, of C to E (or D to F). It is therefore clear that the ratio of the plane number A to the plane B is the duplicate of that which C has to E (or D to F), corresponding side to corresponding side. Therefore, between two similar plane numbers, and so on. Which was to be demonstrated.

SCHOLIVM.

Since it has been shown that A, G, B are proportional in the ratio of C to E (or D to F), it is evident that between the two similar plane numbers A and B there falls a mean proportional G, in the ratio of the corresponding sides C, E (or D, F) that were taken.

It is also established from what has been said that the mean proportional G and either of the plane numbers A, B have a common measure. For since A, G, B have been shown proportional in the ratio C to E (or D to F) — that is, A is to G, and G to B, as C is to E (or D to F) — and since E, F, the sides, measure the number B, of which they are the sides (consequents measuring a consequent, if we speak of the ratios G to B and C to E, or D to F), then C, D will also measure G (antecedents measuring an antecedent), since G is to B as C is to E (or D to F). But C, D, the sides, also measure the number A, of which they are sides. Therefore G and A have a common measure, both C and D; and hence they have a common measure with one another. Again, since A is to G as C is to E (or D to F), and since C, D, the sides, measure their own plane A (antecedents measuring an antecedent), then E, F will also measure G (consequents measuring a consequent). Therefore, since E, F, the sides, also measure their own plane B, G and B will have a common measure, both E and F; and so they have a common measure with one another.

From this demonstration it is also left manifest that the common measures of the two prior numbers A, G are C, D, the sides of the prior plane A; while the common measures of the latter pair G, B are E, F, the sides of the latter plane B.

THEOR. 17. PROPOS. 19.

[Margin: xviii.]

Between two similar solid numbers there are two mean proportional numbers; and a solid number has to a solid the triplicate ratio of that which the corresponding side has to the corresponding side.

Let A and B be similar solid numbers; let the sides of the former be C, D, E, and those of the latter, proportional to them, F, G, H — so that C is to D as F is to G, and D is to E as G is to H. I say that between A and B there fall two mean proportionals, and that the ratio of A to B is the triplicate of that which the corresponding sides C to F (or D to G, or E to H) have. For let C and D, multiplying one another, make I; and let F and G, multiplying one another, make K. Likewise let D and F, multiplying one another, make L. Finally let E and H, multiplying one another, make M and N. Since, then, C, D, E are proportional to F, G, H, they will also be proportional alternately — namely, as C is to F, so D is to G, and E to H. Now since D, multiplying C and F, made I and L, [Margin: a — 17. septi. (*Elements* VII.17)] as C is to F, so will I be to L. In like manner, since F, multiplying D and G, made L and K, [Margin: b — 17. septi. (*Elements* VII.17)] as D is to G, so will L be to K. Therefore I, L, K are continued proportionals in the ratio of C to F (or D to G, or E to H). And since the solid A is made from the mutual multiplication of the sides C, D, E, and I was made from the mutual multiplication of C, D, it follows that E, multiplying I, makes A. In the same way, since the solid B is made from the mutual multiplication of the sides F, G, H, and K was made from the mutual multiplication of F, G, the number H, multiplying K, will make B. Therefore, since E, multiplying I and L, made A and M, [Margin: c — 17. septi. (*Elements* VII.17)] A will be to M as I is to L — that is, as C is to F (or D to G, or E to H). By the same reasoning, since H, multiplying L and K, made N and B, [Margin: d — 17. septi. (*Elements* VII.17)] N will be to B as L is to K — that is, as C is to F (or D to G, or E to H). [Margin: e — 18. septi. (*Elements* VII.18)] Moreover, M is to N as E is to H, since E and H, multiplying L, made M and N. Therefore A, M, N, B are continued proportionals in the ratio of C to F (or D to G, or E to H); and hence between the similar solids A, B there fall two mean proportionals M, N in continued proportion.

A, 30. M, 60. N, 120. B, 240.
I, 6. L, 12. K, 24.
C, 2. D, 3. E, 5. F, 4. G, 6. H, 10.

Now since A, M, N, B are continued proportionals, the ratio of A to B is the triplicate of that which A has to M. But A is to M as C is to F (or D to G, or E to H). Therefore A to B — solid to solid — will also have the triplicate ratio of that which C has to F (or D to G, or E to H), side to corresponding side. Therefore, between two similar solid numbers there fall two means, and so on. Which was to be shown.

SCHOLIVM.

Since it has been demonstrated that A, M, N, B are proportional in the ratio of C to F (or D to G, or E to H), it is clear that between the two similar solids A and B there fall two mean proportionals M and N, in the ratio of the corresponding sides C, F (or D, G, or E, H) that were taken.

From what has been said, it is also evident that the two mean proportionals M, N and either of the solids A, B have a common measure with one another. For since A, M, N, B have been shown proportional in the ratio C to F (or D to G, or E to H) — that is, A is to M, and M to N, and N to B, as C is to F (or D to G, or E to H) — and since F, G, H, the sides, measure their own solid B (consequents measuring a consequent, if we speak of the ratios N to B and C to F, or D to G, or E to H), then C, D, E will also measure N (antecedents measuring an antecedent), since N is to B as C is to F (or D to G, or E to H). But C, D, E also measure M. (For since M was made, by construction, from E into L, E measures M. Next, since M, N, B are proportional to I, L, K, and K measures B — because B was made from K into H — I will also measure M. But C, D, the sides, measure their own plane I. [Margin: c — 11. pro. [?]] (Prop. 11 [?])] Therefore C, D will also measure M; and so C, D, E will measure M.) And likewise they measure A too — namely, the sides measuring their own solid. Therefore A, M, N have a common measure — C, D, and E alike; and so they have a common measure with one another.

Again, since A is to M as C is to F (or D to G, or E to H), and since C, D, E, the sides, measure their own solid A (antecedents measuring an antecedent), then F, G, H will also measure M (consequents measuring a consequent). But F, G, H also measure N. (For since N was made from H into L, by construction, H measures N. Next, since A, M, N are proportional to I, L, K, and I measures M, K will also measure N. Since, then, F, G, the sides, measure their own plane K, F, G will also measure N; and so F, G, H will measure N.) And likewise they measure B too — namely, the sides measuring their own solid. Therefore M, N, B have a common

measure — F, G, and H alike. Hence they have a common measure with one another.

A, 30. M, 60. N, 120. B, 240.

I, 6. L, 12. K, 24.

C, 2. D, 3. E, 5. F, 4. G, 6. H, 10.

From all this it plainly follows that the common measures of the three prior numbers A, M, N are C, D, E, the sides of the prior solid A; while F, G, H, the sides of the latter solid B, are the common measures of the three latter numbers M, N, B.

Now, since a solid number has three sides, from whose mutual multiplication it is generated, let us here demonstrate that the same solid number is produced whether the first side is multiplied into the second and the number so produced into the third; or the first into the third and the number generated into the second; or, finally, the second into the third and the resulting number into the first. Indeed, let us show that, given any numbers whatever, the same number is always generated from their mutual multiplication, in whatever order they may be permuted among themselves. This matter is of great use in arithmetical questions. Let, then, such a theorem be proposed:

Given any number of numbers whatever, the same number will always be produced from their mutual multiplication, in whatever order they permute their arrangement among themselves.

First, let three numbers A, B, C be given; and from A into B let D be made, and from D into C let E be made. I say that the same E is produced if from A into C, F is made and F is multiplied into B; likewise if from B into C, G is made and G is multiplied into A. For since C, multiplying D, makes E, [Margin: f — 15. def. (*Elements* VII, Def. 15)] as E is to D, so is C to unity. But as C is to unity, [Margin: g — 15. def. (*Elements* VII, Def. 15)] so also is F to A, since A, multiplying C, makes F. Therefore, as E is to D, so is F to A. And as D is to B, [Margin: h — 15. def. (*Elements* VII, Def. 15)] so is A to unity, because A, multiplying B, makes D. Therefore, from equality, as E is to B, so will F be to unity; [Margin: i — 19. septi. (*Elements* VII.19)] and hence the number made from F into unity — that is, F itself — will be equal to the number made from B into F, F being the product from A into C. Therefore, just as the number E is made from A into B and the product into C, so the same E is made from A into C and the product into B. Which is the first case.

A, 3. B, 5. C, 8.

D, 15. E, 120. F, 24. G, 40.

E, F,
D, A,
B, unity

Again, since E is made from C into D, [Margin: k — 15. def. (*Elements* VII, Def. 15)] as E is to D, so is C to unity. But as C is to unity, [Margin: l — 15. def. (*Elements* VII, Def. 15)] so also is G to B, because G is made from B into C. Therefore, as E is to D, so is G to B. And as D is to A, [Margin: m — 25. def. [?] (*Elements* VII, Def. 25 [?] — likely misprint for 15. def.)] so is B to unity, because D is made from A into B. Therefore, from equality, as E is to A, so will G be to unity; [Margin: n — 19. sept. (*Elements* VII.19)] and hence the number made from E into unity — that is, E itself — will be equal to the number generated from A into G, G being the product from B into C. Therefore, just as E is generated from A into B and the product into C, so the same E is produced from B into C and the product into A. Which is the second case.

E, G,
D, B,
A, unity

Next, let there be four numbers A, B, C, D; and from A into B, and the product into C, and the product into D, let E be made. I say that the same E is generated:

- from A into B, and the product into D, and the product into C;
- from A into C, and the product into B, and the product into D;
- from A into C, and the product into D, and the product into B;
- from A into D, and the product into B, and the product into C;
- from A into D, and the product into C, and the product into B;
- from B into C, and the product into A, and the product into D;
- from B into C, and the product into D, and the product into A;
- from B into D, and the product into A, and the product into C;
- from B into D, and the product into C, and the product into A;
- from C into D, and the product into A, and the product into B;
- from C into D, and the product into B, and the product into A.

A, 2. B, 3. C, 4. D, 5. E, 120.

—so that, besides the first multiplication, by which all four numbers are multiplied together in order, there arise eleven distinct multiplications, all producing the same number every time.

For since, as was shown in the case of three numbers, the same number results whether the number generated from A into B is multiplied first into C and then this product into D, or first into D and then this product into C, what was proposed in the first place is established. Next, since, as was shown in the case of three, the same number that arises from A into B and the product into C is the one that arises from A into C and the product into B, it is clear that the same number is generated both from A into B, the product into C, and the product into D, and from A into C, the product into B, and the product into D — which is the second case.

(Continuation of Clavius's inserted, un-numbered theorem on the order-independence of a continued product. The running example throughout is $A = 2$, $B = 3$, $C = 4$, $D = 5$, whose full product is $E = 120$. Cases one and two were given in the preceding pages; the enumeration of the eleven distinct multiplications, besides the first, resumes here at the third.)

Thirdly. Since it was shown for three numbers that the same number is produced — whether the number generated from A into C is multiplied first into B and then this product into D, or first into D and then this product into B — it is clear that one and the same number is generated from A into C, then the product into D, then that product into B. Since, then, that number is equal to the first product just shown, this one too will be equal to the same. This is the third case.

Fourthly. Since it was shown for three numbers that the same number arises from A into B, then the product into D, as arises from A into D, then the product into B, there will likewise be generated the same number from A into B, then the product into D, then the product into C. But that number was shown in the first place to be equal to the one made from A into B, then the product into C, then the product into D. Therefore this one also is equal. This is the fourth case.

Fifthly. Since it was demonstrated for three numbers that the same number is generated from A into C, then the product into D, as is generated from A into D, then the product into C, there will be produced the same number from A into C, then the product into D, then the product into B, as is produced from A into D, then the product into C, then the product into B. Since, then, that number was shown in the third place to be equal to the one made from A into B, then the product into C, then the product into D, this one too will be equal to the same. This is the fifth case.

Sixthly. Since we demonstrated for three numbers that the same number arises from A into B, then the product into C, as arises from B into C, then the product

into A, it is evident that one and the same number is procreated both from A into B, then the product into C, then the product into D, and from B into C, then the product into A, then the product into D. This is the sixth case.

Seventhly. Since we showed for three numbers that the same number is generated whether the product [from B into C] is multiplied first into D, or first into D and then this product into A, it is established that the same number arises from B into C, then the product into D, then the product into A, as arises from B into C, then the product into A, then the product into D. But this latter was shown just above to be equal to the one made from A into B, then the product into C, then the product into D. Therefore the former also. This is the seventh case.

Eighthly. Since it was shown for three numbers that the same number is procreated from A into B, then the product into D, as from B into D, then the product into A, there will likewise be generated the same number from A into B, then the product into D, then the product into C, as from B into D, then the product into C, then the product into A. But that number was shown in the first place to be equal to the one made from A into B, then the product into C, then the product into D. Therefore this one also. This is the eighth case.

Ninthly. Since it was demonstrated for three numbers that the same number arises from B into C, then the product into D, as from B into D, then the product into C, there will be procreated the same number from B into C, then the product into D, then the product into A, as from B into D, then the product into C, then the product into A. But that number was shown in the seventh place to be equal to the one made from A into B, then the product into C, then the product into D. Therefore this one also. This is the ninth case.

A, 2. B, 3. C, 4. D, 5.
E, 120.

Tenthly. Since it was demonstrated for three numbers that the same number is generated from A into C, then the product into D, as from C into D, then the product into A, there will also be produced the same number from A into C, then the product into D, then the product into B, as from C into D, then the product into A, then the product into B. But that number, as was shown in the third place, is equal to the one made from A into B, then the product into C, then the product into D. Therefore this one also. This is the tenth case.

Lastly. Since it was shown for three numbers that the same number is generated from B into C, then the product into D, as from C into D, then the product into B, there will also be procreated the same number from B into C, then the product

into D, then the product into A, as from C into D, then the product into B, then the product into A. But that number was shown in the seventh place to be equal to the one made from A into B, then the product into C, then the product into D. Therefore this one too will be equal to the same. This is the eleventh case.

The same manner of arguing must be used with five or more numbers, provided only that with five one assumes what has already been demonstrated for four, and with six what was demonstrated for five, and so on. Thus with the five numbers A, B, C, D, E it is plain — where we have altered the order three times, and yet always the same number is procreated from their continued multiplication among themselves. For the product of A into B, together with C, D, E, constitutes four numbers; therefore, in whatever way they interchange their order among themselves, they will always generate the same number. And so both the second order and the third will produce the same number as the first. Again, since the three numbers A, B, C, however they change their order, make the same number, it follows that the fourth order produces exactly the same number as the first — and so with the rest.

A. B. C. D. E.
A. B. C. E. D.
A. B. E. D. C.
B. C. A. D. E.

THEOR. 18. PROPOS. 20.

[Margin: xvij.]

If between two numbers one mean proportional number falls, those numbers will be similar plane numbers.

Let a mean proportional C fall between A and B. I say that A and B are similar plane numbers. Take D and E, the least numbers in the ratio A, C, B. Since, then, D and E are the least in the ratio of A to C, [Margin: a — Elements VII.21] they will measure A and C equally; let them measure by F. Similarly they will measure C and B equally; let them measure by G. [Margin: b — Axiom 9] And so F, multiplying D and E, will produce A and C; [Margin: c — Axiom 9] likewise G, multiplying the same D and E, will produce C and B. Since, therefore, E, multiplying F and G, made C and B, [Margin: d — Elements VII.17] it follows that as C is to B, so is F to G. But as C was to B, so was D to E. Therefore as D is to E, so is F to G; and, by permutation, as D is to F, so is E to G. Now since F, multiplying D, made A, A will be a plane number whose sides are D and F. In the same way, since G, multiplying E, made B, B too will be a plane number whose sides are E

and G. Since, then, these sides have been shown to be proportional — that is, D is to F as E is to G — A and B will, by definition, be similar plane numbers. Therefore, if between two numbers one mean proportional falls, and so on. Which was to be demonstrated.

A, 18. C, 24. B, 32.
D, 3. E, 4. F, 6. G, 8.

THEOR. 19. PROPOS. 21.

[Margin: xix.]

If between two numbers two mean proportional numbers fall, those numbers are similar solids.

Let two mean proportionals C, D fall between A and B. I say that A and B are similar solids. Take the three least numbers E, F, G in the ratio A, C, D, B. [Margin: a — Elements VIII.20] Since, then, a mean proportional F falls between E and G, E and G will be similar plane numbers: let the sides of E be H, I, and the sides of G be K, L, proportional to those. And since E, F, G, being the least in the ratio of A, C, D, B, [Margin: b — Elements VII.21] measure A, C, D — which have the same ratio as they — equally, let them measure by M. [Margin: c — Elements VII.21] In the same way, since E, F, G are also the least, they equally measure C, D, B, which have the same ratio as they; let them measure by N. [Margin: d — Axiom 9] Thus M, multiplying E, F, G, produces A, C, D; and N, multiplying the same E, F, G, produces C, D, B. Now E was produced from the mutual multiplication of its sides H and I; likewise G, from the mutual multiplication of its sides K and L. Therefore A is produced from the mutual multiplication of H, I, M; and B from the mutual multiplication of K, L, N. And so A, by definition, is a solid number having as its sides H, I, M; and B too is a solid having as its sides K, L, N. But since M and N, multiplying F, produce C and D, as we showed, [Margin: e — Elements VII.18] it follows that C is to D as M is to N. [Margin: f — Elements VII.17] And C and D are in the same ratio as E and F, because N, multiplying E and F, made C and D; they therefore have the same ratio as HK, or as I, L. For between the similar planes E, G falls the mean proportional F, by the corollary to Proposition 19 of this book, in the ratio of the homologous sides H, K, or I, L. Therefore H will also be to K, and I to L, as M is to N; and, by permutation, H is to I as K is to L, and I is to M as L is to N. The sides H, I, M are therefore proportional to the sides K, L, N; and for that reason the solid numbers A and B are similar. Wherefore, if between two numbers two mean proportionals fall, and so on. Which was to be demonstrated.

A, 8. C, 12. D, 18. B, 27.
E, 4. F, 6. G, 9.
H, 2. I, 3. M, 2. K, 3. L, 3. N, 3.

SCHOLIVM.

We have set down two examples. In the first of them it plainly appears that the unit E is a plane number, and the units H, I its sides — though improperly so, as we noted in the definition of a plane number. For if we exclude the unit from among plane numbers, we shall not be able, by this argument of Euclid's, to demonstrate that the numbers A and B are similar solids. The same difficulty will arise with all other numbers that contain two mean proportionals in a multiple ratio — of which kind are A and B in this same first example. But this is absurd, since Euclid states the proposition in general terms and demonstrates it without any exception.

THEOR. 20. PROPOS. 22.

[Margin: xx.]

If three numbers be in continued proportion, and the first is a square, then the third will also be a square.

Let there be three numbers A, B, C in continued proportion, and let the first of them, A, be a square. I say that the third, C, is also a square. For since a mean proportional falls between A and C, [Margin: a — Elements VIII.20] A and C will be similar plane numbers. Therefore, A being a square, C, which is similar to it, will also be a square. If, then, three numbers be in continued proportion, and so on. Which was to be demonstrated.

A, 9. B, 54. C, 324.

THEOR. 21. PROPOS. 23.

[Margin: xxi.]

If four numbers be in continued proportion, and the first is a cube, then the fourth will also be a cube.

Let there be four numbers A, B, C, D in continued proportion, and let the first, A, be a cube. I say that the fourth, D, is also a cube. For since two mean

proportionals B, C fall between A and D, [Margin: a — Elements VIII.21] A and D will be similar solids. Therefore, A being a cube, D, which is similar to it, will also be a cube. Wherefore, if four numbers be in continued proportion, and so on. Which was to be demonstrated.

A, 27. B, 45. C, 75. D, 125.

SCHOLIUM.

This is the received demonstration of the two preceding propositions, found in all the interpreters of Euclid whom I have seen; but anyone who cares to examine it closely will find it decidedly defective and incomplete. For since, at Definition 21 of Book 7, we handed down that two plane or solid numbers can be similar even though not for *any* sides whatever of the one can other sides of the other be exhibited proportional — it being enough that for *some* sides of the one certain sides of the other are proportional — anyone could, with perfect right, deny that, if one of two similar plane numbers be a square, the other is also a square, and that, if one of two similar solids be a cube, the other too is a cube; yet in the demonstration this was assumed as granted and as evident to all. For, given the two similar plane numbers 36 and 64, it is enough that for two sides of the former, such as 3 and 12, two other sides of the latter be exhibited proportional, namely 4 and 16. Hence, even though the former be a square, having two equal sides 6 and 6, one may rightly doubt — indeed altogether deny — that the latter has two other sides proportional to these, that is, equal to one another, and so is a square: just as it is likewise manifest that to these sides of the former, 4 and 9, or 2 and 18, no other sides in the latter correspond proportional. If, then, to these sides of the former number no other sides are found in the latter proportional, although the numbers themselves are similar, why should we grant, without any demonstration, that to these equal sides of the former, 6 and 6, two others can be assigned in the latter proportional — that is, equal to one another as well? The same must be said of similar solids. For this reason we shall demonstrate both propositions of Euclid otherwise, in the following manner.

Let there be three numbers A, B, C in continued proportion, and let the first, A, be a square. I say that C, the third, is also a square. For, taking D, the side of the square A — since D, multiplied by itself, makes A — D and A will, by the scholium to Proposition 9 of this book, be in continued proportion from the unit;

and so, by conversion, A will be to D as D is to the unit. And thus, since between the number A itself — and both the number C and the unit — mean proportionals fall equal in multitude, namely one, there will fall, by Theorem 3 of the scholium

to Proposition 10 of this book, just as many between the unit and the number C, namely one, which let be E. Since, therefore, the unit and E, C are in continued proportion, C will be produced from E multiplied into itself, by the scholium to Proposition 10 of this book. And so C will, by definition, be a square, whose side is E.

A, 36. B, 48. C, 64.
D, 6. E, 8.
unitas.

Otherwise. Taking three numbers D, E, F, the least in the ratio of A to B and of B to C, D will measure A, and F will measure C, equally, by what we showed at Proposition 21 of Book 7. And since the extremes D, F of the three least numbers are, by Corollary 1 of Proposition 2 of this book, squares — and A too is a square, by hypothesis — [Margin: b — Elements VIII.11] one mean proportional, say G, will fall between the squares A and D. And since, by equality, as A is to C, so is D to F, and, by permutation, as A is to D, so is C to F, [Margin: c — Elements VIII.8] one mean proportional, namely H, will also fall between C and F. Since, then, F, the first, measures C, the last, [Margin: d — Elements VIII.7] it will measure the second, H, as well. Now, taking I, the side of the square F, let I measure the number K as many times as F measures H itself, so that H is to F, and K to I, in the same multiple proportion. Let L also be the square of K. [Margin: e — Elements VIII.11] Thus, since the ratio of L to F, square to square, is the duplicate of the ratio of K to I, side to side — that is, of H to F — while the ratio of C to F is likewise the duplicate of the same ratio H to F, by the definition, so that by conversion C, H, F are also proportional, it follows that L is to F as C is to F. And therefore L and C are equal. Since, then, L is a square by construction, C too will be a square.

A, 36. B, 48. C, 64.
G, 18. H, 32.
D, 9. E, 12. F, 16.
L, 64. K, 8. I, 4.

Otherwise. [Margin: f — Elements VIII.20] Since A and C are similar planes, let their sides be proportional: D, E those of A, and F, G those of C, so that D is to E as F is to G; and let H be taken as the side of the square A. Since, then, the same number A is produced both from D into E and from H into itself, [Margin: g — Elements VII.20] D, H, E will be in continued proportion. Since, therefore, F is to G as D is to E, and a mean proportional H falls between D and E, [Margin: h — Elements VIII.8] one mean proportional, say I, will also fall between F and G. Wherefore, since F, I, G are in continued proportion, [Margin: i — Elements VII.20] the same number will arise from F into G as from I into itself. But C arises

from F into G. Therefore C too will arise from I into itself; and so C will, by definition, be a square, whose side is I.

A, 36. B, 48. C, 64.

H, 6. I, 8.

D, 3. E, 12. F, 4. G, 16.

A, 36. B, 48. C, 64.

H, 6. I, 8.

D, 6. E, 6. F, 8. G, 8.

Again, let there be four numbers A, B, C, D in continued proportion, and let the first, A, be a cube. I say that the fourth, D, is also a cube. For, taking E, the side of the cube A, let the number F be made from E into itself; and so, by definition, the cube A is made from E into F. Since, then, E multiplied by itself makes F, and multiplied by F makes A, E, F, A will, by the scholium to Proposition 9 of this book, be in continued proportion from the unit; and therefore, by conversion, the numbers A, F, E, and the unit will likewise be proportional. And so, since between both the number D and the unit — and the same number A — mean proportionals fall equal in multitude, namely two, there will fall, by Theorem 3 of the scholium to Proposition 10 of this book, just as many means between the unit and the number D, which let be G, H. And so, since the unit and the numbers G, H, D are in continued proportion, H will be made from G into itself, and D from G into the product H, as was demonstrated by us at Proposition 10 of this book. Wherefore D is a cube, by definition, whose side is G.

A, 64. B, 160. C, 400. D, 1000.

F, 16. H, 100.

E, 4. G, 10.

unitas.

Otherwise. Having found the four least numbers E, F, G, H in the ratio of A to B, of B to C, and of C to D, E will measure A, and H will measure D, equally, by what we demonstrated at Proposition 21 of Book 7. And since E, H, the extremes of the four least numbers, are cubes, by Corollary 1 of Proposition 2 of this book — while A too is a cube, by hypothesis — [Margin: k — Elements VIII.12] two mean proportionals, say I, K, will fall between the cubes E and A. And since, by equality, as A is to D, so is E to H, and, by permutation, as A is to E, so is D to H, [Margin: l — Elements VIII.8] two mean proportionals, say L, M, will also fall between H and D. Since, then, H, the first, measures D, the extreme, [Margin: m — Elements VIII.7] it will measure the second, L, as well. Then, taking N, the side of the cube H, let N measure the number O as many times as H measures L, so that L is to H, and O to N, in the same multiple proportion; and let P also be the cube of O.

[Margin: n — Elements VIII.12] Thus, since the ratio of P to H, cube to cube, is the triplicate of the ratio of O to N, side to side — that is, of L to H — while the ratio of D to H is likewise the triplicate of the same ratio L to H, by the definition, so that by conversion D, M, L, H are also proportional, P will be to H as D is to H. And therefore P and D will be equal. Wherefore, since P is a cube by construction, D too will be a cube.

THEOR. 22. PROPOS. 24.

[Margin: xxij.]

If two numbers have to one another the ratio which a square number has to a square number, and the first is a square, then the second will also be a square.

For let A be to B as C, a square, is to the square D, and let A be a square. I say that B is also a square. For since A is to B as C is to D, [Margin: a — Elements VIII.11] and one mean proportional, namely E, falls between the squares C and D, [Margin: b — Elements VIII.8] one mean, say F, will also fall between A and B. Since, therefore, the three numbers A, F, B are in continued proportion, and A, the first, is a square, B, the third, will also be a square. [Margin: c — Elements VIII.22] Wherefore, if two numbers have to one another the ratio which a square number has to a square number, and so on. Which was to be shown.

A, 36. F, 48. B, 64.
C, 9. E, 12. D, 16.

COROLLARIVM.

It is clear from these things that the ratio of any square number to any non-square number can in no way be exhibited between two square numbers. For if it could be exhibited, [Margin: d — Elements VIII.24] then both the former numbers — having the ratio which the exhibited squares have — would also be squares, since the first is posited to be a square. But this is absurd; for the second is posited to be non-square. Hence numbers in a double ratio do not have the propor-

[Continuation of the Corollary begun on the preceding page — that a square-to-non-square ratio cannot be exhibited between two squares.]

do not have to one another the ratio that a square has to a square. For if they did, all these doubling numbers — 4, 8, 16, 32, 64, 128, and so on — would be squares. Since 4 is a square to begin with, 8 too would have to be a square [Margin: f — *Elements* VIII.24]; and then 16 and 32 as well, and so on [Margin: g — *Elements* VIII.11] — which is absurd [reading uncertain: the sequence is printed "16.&32.&0."; evidently "&c."]. For a mean proportional would fall between 4 and 8, between 8 and 16, between 16 and 32, and so on, if they were squares; yet it has been shown in the scholium to Prop. 8 of this book that no mean proportional whatever can fall between numbers standing in a double ratio.

In the same way, numbers in a quintuple ratio will not have to one another the ratio that a square number has to a square number. For if they did, a mean proportional would fall between them [Margin: h — *Elements* VIII.11]; and hence one would fall between 5 and 1 as well [Margin: i — *Elements* VIII.8], the least numbers in quintuple ratio — which we have demonstrated to be impossible in the scholium to Prop. 8 of this book.

THEOR. 23. PROPOS. 25.

[Margin: xxiiij.]

If two numbers have to one another the ratio that a cube number has to a cube number, and the first is a cube, then the second will also be a cube.

Let A be to B as the cube C is to the cube D, and let A be a cube. I say that B too is a cube. For since A is to B as C is to D, and since two cube mean proportionals — call them E and F — fall between the cubes C and D [Margin: a — *Elements* VIII.12], two means will likewise fall between A and B — call them G and H [Margin: b — *Elements* VIII.8].

A, 8. G, 12. H, 18. B, 27.
C, 64. E, 96. F, 144. D, 216.

Now since the four numbers A, G, H, B are in continued proportion, and A, the first, is a cube, B, the fourth, will also be a cube [Margin: c — *Elements* VIII.23]. And so, if two numbers have to one another the ratio a cube number has to a cube number, etc. Which was to be demonstrated.

COROLLARIUM.

[Margin: d — *Elements* VIII.25]

It is also clear from these results that the ratio of any cube number to any non-cube number cannot be exhibited between two cube numbers. For if it could be, then both of the former numbers — those having the ratio found between the two cubes — would themselves be cubes as well, since the first is assumed to be a cube. And that is absurd, for the second is assumed to be non-cube.

THEOR. 24. PROPOS. 26.

[Margin: xxiv.]

Similar plane numbers have to one another the ratio that a square number has to a square number.

Let A and B be similar plane numbers. I say that A is to B as some square number is to some other square number. For since A and B are similar planes, a single mean proportional — namely C — falls between them [Margin: a — *Elements* VIII.18].

A, 20. C, 30. B, 45.
D, 4. E, 6. F, 9.

Take then the three least numbers D, E, F in continued ratio with A, C, B; the extremes D and F will be squares, by Corollary 1 of Prop. 2 of this book. Since, therefore, *ex aequali*, A is to B as D is to F, it is clear that A is to B as one square, namely D, is to another square, namely F. Therefore similar plane numbers have to one another the ratio, etc. Which was to be shown.

[The lettered magnitude-figure D, 4 · E, 6 · F, 9 with A, 20 · C, 30 · B, 45 is printed twice in the side column, once against each half of the demonstration; the values are identical.]

SCHOLIUM.

We shall also easily demonstrate the converse of this, namely:

Numbers that have to one another the ratio a square number has to a square number are similar planes.

A, 8. B, 18.
C, 16. D, 36.

Let the numbers A, B have to one another the ratio that the squares C, D have. I say that A, B are similar planes. For since a single mean proportional falls between the squares C, D [Margin: b — *Elements* VIII.11], and since C is to D as A is to B, a mean proportional will also fall between A and B [Margin: c — *Elements* VIII.8]. Therefore A and B are similar planes [Margin: d — *Elements* VIII.20].

From this it is evident that plane numbers which are not similar do not have the ratio a square has to a square. For if they did, they would be similar planes, as was just demonstrated — which is absurd, since they are assumed not to be similar.

THEOR. 25. PROPOS. 27.

[Margin: xxv.]

Similar solid numbers have to one another the ratio that a cube number has to a cube number.

Let A, B be similar solids. I say that A is to B as some cube number is to some other cube. For since A, B are similar solids, two mean proportionals — call them C, D — fall between them [Margin: a — *Elements* VIII.19].

A, 240. C, 360. D, 540. B, 810.
E, 8. F, 12. G, 18. H, 27.

Take the four least numbers E, F, G, H in the continued proportion A, C, D, B; the extremes E, H will be cubes, by Corollary 1 of Prop. 2 of this book. Since, therefore, *ex aequali*, A is to B as E is to H, it follows that A is to B as one cube, namely E, is to another cube, namely H. Similar solid numbers, therefore, have to one another the ratio [a cube has to a cube], etc. Which was to be demonstrated.

SCHOLIVM.

We shall also demonstrate the converse of this, namely:

Numbers that have to one another the ratio a cube number has to a cube number are similar solids.

A, 16. B, 54.
C, 64. D, 216.

Let the numbers A, B have to one another the ratio that the cubes C, D have. I say that A, B are similar solids. For since A is to B as C is to D, and since two mean proportionals fall between the cubes C, D [Margin: b — *Elements* VIII.12], two

means will also fall between A, B [Margin: c — *Elements* VIII.8]. Therefore A and B are similar solids [Margin: d — *Elements* VIII.21].

From all this it is clearly inferred that no numbers standing in a double, superparticular, or superbipartient ratio are similar planes or similar solids [Margin: e — *Elements* VIII.18]. For if they were similar planes, a single mean proportional would fall between them — which, it was long ago shown in the scholium to Prop. 8 of this book, is impossible. By the same reasoning they will not be similar solids, since two means cannot fall between them; for otherwise two means would also fall between the least numbers of those same ratios [Margin: f — *Elements* VIII.8]. But that cannot happen, since these differ from one another by only a single unit, or at most by two, as was set out in the aforesaid scholium; and it is certain that between such numbers two numbers cannot be interposed, let alone two mean proportionals.

Likewise, no two prime numbers can be similar planes or similar solids, since they cannot have proportional sides. For any plane number that is prime has as its sides only unity and itself (though the latter improperly). Thus the plane numbers 19 and 23 have as sides 1 and 19, and 1 and 23; and since they are produced by the mutual multiplication of these — which are plainly not proportional [they are not similar]. And any solid number that is likewise prime has as its sides only two units and itself: thus the solid numbers 29 and 47 have as sides $1 \cdot 1 \cdot 29$ and $1 \cdot 1 \cdot 47$, since they are produced by the mutual multiplication of these. And it is evident that these cannot be proportional.

Again, no two numbers prime to one another which are not squares or cubes (even though neither of them is prime) can be similar planes or similar solids. For if two such numbers prime to one another were said to be similar planes or solids, one mean proportional would fall between them, or two [Margin: g — *Elements* VIII.18 & 19]. Since, then, the two extremes are assumed to be prime to one another, all three (or all four) will be prime to one another, because no number can measure them all as a common measure, on account of the two extremes being prime to one another. Hence the least numbers [in that ratio] will be in continued proportion, as we demonstrated in the scholium to Prop. 24 of Book 7. And therefore, by Corollary 1 of Prop. 2 of this book, the two extremes will be squares or cubes — which is absurd, for they are assumed to be neither squares nor cubes.

From this it follows that if two numbers are similar planes or similar solids, of which the smaller is prime, the smaller measures the larger. For if it did not measure it, the two given numbers would be prime to one another [Margin: h —

Elements VII.31]; and hence, as we have just shown, they could not be similar planes or solids — which is absurd and contrary to the hypothesis. But we shall demonstrate this affirmatively as well, thus. First let A, B be two similar plane numbers, with A the smaller and prime. I say that A measures B. For since A and B are assumed to be similar planes, they will have proportional sides.

A, 3. B, 48.

C, 1. D, 3. E, 4. F, 12.

Since, then, the sides of the prime number A are C (unity) and the number D equal to A — for no number other than C, unity, and the number D equal to A measures the prime number A — let E, F be the sides of B, proportional to the sides C, D, so that C is to E as D is to F. Then, by alternation, C will be to D as E is to F [Margin: i — *Elements* VII.19]. Therefore the number produced from C, the first, into F, the fourth, is equal to the one produced from D, the second, into E, the third. But from C (unity) into F comes F itself. So the same number F comes from D into E. Hence D measures F [Margin: k — *Elements* VII.4]. But F measures B [Margin: l — *Elements* VII, Axiom 4], since B is generated from E into F. Therefore D — that is, A, which is equal to it — also measures B [Margin: m — *Elements* VII, Axiom 11], which is what was proposed.

From this it is evident that two numbers prime to one another, of which the smaller is prime, cannot be similar planes. For if they were similar, the smaller would measure the larger, as we just showed. And since it also measures itself, they would not be prime to one another but composite — which is contrary to the hypothesis.

Next let A, B be two similar solids, with A the smaller and prime. I say that A measures B. For since A and B are similar solids, they will have proportional sides.

A, 3. B, 24.

B, 1. C, 1. D, 3. E, 2. F, 2. G, 6.

Since, then, the sides of the prime number A are B, C (units) and the number D equal to A — for no number other than unity and the number D equal to A measures the prime number A — let E, F, G be the sides of the number B, proportional to the sides B, C, D, so that B is to E as C is to F and D is to G. Now since C is to F as D is to G, by alternation C will be to D as F is to G [Margin: n — *Elements* VII.19]. Therefore the number produced from C, the first, into G, the fourth, is equal to the one produced from D, the second, into F, the third. But from C (unity) into G comes G itself. So the same number G comes from D into F. Hence D measures G [Margin: o — *Elements* VII.4]. But G measures B [Margin: p —

Elements VII, Axiom 4], since G is a side of B. Therefore D — that is, A, which is equal to it — also measures B [Margin: q — *Elements* VII, Axiom 11]. Which is what was proposed.

And from this it is likewise established that two numbers prime to one another, of which the smaller is prime, cannot be similar solids. For if they were similar, the smaller would measure the larger, as we just showed; and since it also measures itself, they would not be prime to one another but composite — which is contrary to the hypothesis.

And so it is quite easy to find two plane, or two solid, numbers that are not similar. For if we take two numbers standing in a double, superparticular, or superbipartient ratio; or else two prime numbers, or two numbers prime to one another, neither of which is a square or a cube; these very numbers will, by what has been set out, be plane or solid numbers that are not similar.

Again, any two numbers of which one is a square and the other not a square are plane numbers that are not similar — such as 16 and 20. For if they were similar planes, they would have the ratio a square has to a square [Margin: r — *Elements* VIII.28]; and since 16 is a square, 20 would also be a square [Margin: s — *Elements* VIII.24] — which is absurd, for it is assumed not to be a square.

By the same reasoning, any two numbers of which one is a cube and the other not a cube are solid numbers that are not similar — such as 27 and 40. For if they were similar solids, they would have the ratio a cube has to a cube [Margin: t — *Elements* VIII.27]; and since 27 is a cube, 40 would also be a cube [Margin: u — *Elements* VIII.25] — which is absurd, for it is assumed not to be a cube.

FINIS ELEMENTI OCTAVI. — End of the Eighth Book [of the *Elements*].

EVCLIDIS ELEMENTVM NONVM.

Euclid's Ninth Book of the *Elements*.

THEOR. 1. PROPOS. 1.

[Margin: i.]

If two similar plane numbers multiplied into each other make some number, the product will be a square.

Let the two similar plane numbers A, B, multiplied into each other, make C. I say that C is a square. For let A, multiplied into itself, make D, a square. Since, then, A

multiplied into A [makes D], and A [multiplied] into B [makes C], A will be to B as D is to C [Margin: a — *Elements* VII.17]. But between A and B, being similar planes, a single mean proportional falls [Margin: b — *Elements* VIII.18]; therefore between D and C a single mean proportional will also fall [Margin: c — *Elements* VIII.8]. Let E, then, fall, so that D, E, C are in continued proportion.

A, 6. B, 54.

D, 36. E, 108. C, 324.

And so, since the three numbers D, E, C are in continued proportion, and the first, D, is a square by construction, C, the third, will also be a square [Margin: d — *Elements* VIII.22]. Therefore, if two similar plane numbers are multiplied into each other, etc. Which was to be demonstrated.

THEOR. 2. PROPOS. 2.

[Margin: ii.]

If two numbers multiplied into each other make a square, they will be similar planes.

Let the two numbers A, B, multiplied into each other, make C, a square. I say that A, B are similar planes. For let A, multiplied into itself, make D, a square. Since, then, A multiplied into A made D, and A [multiplied] into B made C, A will be to B as D is to C [Margin: a — *Elements* VII.17]. But between D and C, being squares, a single mean proportional falls [Margin: b — *Elements* VIII.11]; therefore between A and B a single mean proportional will also fall [Margin: c — *Elements* VIII.8]. And on that account A and B are similar planes [Margin: d — *Elements* VIII.20]. Therefore, if two numbers multiplied into each other [make a square], etc. Which was to be demonstrated.

A, 6. B, 54.

D, 36. C, 324.

SCHOLIVM.

From these we shall demonstrate four following theorems, not without their use.

I.

If two square numbers multiplied into each other make some number, the product will be a square.

Let the two squares A, B, multiplied into each other, make C. I say that C is a square. For since A and B are similar planes — being, of course, squares — C, produced from them, will be a square [Margin: a — *Elements* IX.1].

A, 4. B, 25.
C, 100.

II.

If two numbers multiplied into each other make a square, and one of them is a square, then the other will be a square as well.

Let the two numbers A, B, multiplied into each other, make C, a square; and let A be a square. I say that B too is a square. For since A and B, multiplied into each other, make C, a square, A and B will be similar planes [Margin: a — *Elements* IX.2]; and so a single mean proportional, namely D, will fall between them [Margin: b — *Elements* VIII.18]. Therefore, since A is a square, B will also be a square [Margin: c — *Elements* VIII.22].

A, 9. D, 12. B, 16.
C, 144.

III.

If two numbers multiplied into each other make a non-square, and one of them is a square, then the other will be a non-square.

Let the two numbers A, B, multiplied into each other, make C, a non-square; and let A be a square. I say that B is a non-square. For if B were said to be a square, then C — the product of the squares A, B — would also be a square, by Theorem 1 of this scholium; which is absurd and contrary to the hypothesis. Therefore B is not a square number.

A, 4. B, 20.
C, 80.

IV.

If two numbers, a square and a non-square, multiplied into each other make some number, the product will be a non-square.

EUCLID'S ELEMENTS, BOOK IX

(Continuation of the Scholium to Proposition 2 — demonstration of sub-theorem IV, "a square multiplied by a non-square makes a non-square." Its enunciation stood at the close of the preceding page.)

Let two numbers, A (a square) and B (a non-square), multiplying each other, make C. I say that C is not a square. For if C were a square, then — since it is produced from A into B, and A is a square — B too would be a square, by Theorem 1 of this scholium; which is absurd and contrary to the hypothesis. Therefore C will not be a square.

A, 9. B, 20.
C, 180.

(9, a square, into 20, a non-square, makes 180, a non-square.)

THEOR. 3. PROPOS. 3. [Margin: iij.]

If a cube number, multiplying itself, produces some number, the product will be a cube.

Let the cube A, multiplying itself, make the number B. I say that B is a cube. For let C be the side of the cube A; from C into itself let D be made, and accordingly let the cube A itself be generated from C into D. Since, then, C multiplying itself made D, [Margin: a — Ax. 7] C measures D by C; [Margin: b — Ax. 5] but the unit also measures C by C. Therefore the unit is the same part of C that C is of D — namely, one named after C. And accordingly [Margin: c — Def. 20] as the unit is to C, so is C to D. Again, since C multiplying D made A, [Margin: d — Ax. 7] D measures A by C; but C also was measuring D by C. Therefore C is the same part of D that D is of A, [Margin: e — Def. 20] and so as C is to D, so is D to A. But as C is to D, so was the unit to C. Therefore as the unit is to C, so is C to D, and D to A; and thus between the unit and the number A two mean proportional numbers, C and D, fall.

But since A measures B by A — because A multiplying itself made B — [Margin: f — Ax. 7] and [Margin: g — Ax. 5] the unit also measures A by A, the unit will be the same part of A that A is of B; [Margin: h — Def. 10] and therefore as the unit is to A, so is A to B. Wherefore, since between the unit and the number A two mean proportionals C and D fall, [Margin: i — Elem. VIII.8] just as many will fall between A and B — namely E and F. Since therefore the four numbers A, E, F, B are in continued proportion, and A, the first, is a cube, [Margin: k — Elem. VIII.23] E [recte: B] too, the fourth, will be a cube. If therefore a cube number multiplying itself, etc. Which was to be demonstrated.

A, 8.
E, 16. D, 4.
F, 32. C, 2.
B, 64. Unit.

THEOR. 4. PROPOS. 4. [Margin: iv.]

If a cube number, multiplying a cube number, makes some number, the product will be a cube.

From the cube A into the cube B let the number C be made. I say that C is a cube. For let A, multiplying itself, make D; [Margin: a — Elem. IX.3] and D will be a cube. Now since A, multiplying A and B, made D and C, [Margin: b — Elem. VII.17] as A is to B, so will D be to C. But [Margin: c — Elem. VIII.12] between A and B, which are cubes, two mean proportionals fall. Therefore [Margin: d — Elem. VIII.8] between D and C also two mean proportionals will fall; and accordingly, [Margin: e — Elem. VIII.23] since D is a cube, C too will be a cube. Wherefore, if a cube number multiplying a cube number, etc. Which was to be shown.

A, 8. B, 27.
D, 64. C, 216.

THEOR. 5. PROPOS. 5. [Margin: v.]

If a cube number, multiplying a certain number, makes a cube, the number multiplied will also be a cube.

From the cube A into the number B let the cube number C be made. I say that B too is a cube. For let A, multiplying itself, make D; [Margin: a — Elem. IX.3] and it will be a cube. Since therefore A, multiplying A and B, made D and C, [Margin: b — Elem. VII.17] as A is to B, so will D be to C. But [Margin: c — Elem. VIII.12] between D and C, which are cubes, two mean proportionals fall. Therefore [Margin: d — Elem. VIII.8] just as many will fall between A and B; and accordingly, [Margin: e — Elem. VIII.22] since A is a cube, B too will be a cube. Wherefore, if a cube number multiplying a certain number, etc. Which was to be shown.

A, 8. B, 27.
D, 64. C, 216.

SCHOLIUM

From these, the following results too will be easily demonstrated, namely:

I.

If a cube number, multiplying a non-cube number, makes some number, the product will be a non-cube.

From A, a cube, into B, a non-cube, let the number C be made. I say that C is not a cube. For if C were a cube, [Margin: a — Elem. IX.5] then the number multiplied, B, would also be a cube — which is not posited.

A, 8. B, 20.
C, 160.

II.

If a cube number, multiplying a certain number, makes a non-cube, the number multiplied is also a non-cube.

From the cube A into the number B let the non-cube C be made. I say that B too is not a cube. For if B were a cube, [Margin: a — Elem. IX.4] then the product C would be a cube — which is contrary to the hypothesis.

A, 8. B, 17.
C, 136.

THEOR. 6. PROPOS. 6. [Margin: vj.]

If a number, multiplying itself, makes a cube, it too will be a cube.

Let the number A, multiplying itself, make B, a cube. I say that A too is a cube. For from A into B let the number C be made, which will be a cube — since A into itself makes B, and C itself is generated from A into B, and so it is "equal, equally equal," as is clear from what we wrote on the definition of a cube. Since, then, B — a cube — multiplying a certain number A makes the cube C, [Margin: a — Elem. IX.5] A too will be a cube. Wherefore, if a number multiplying itself makes a cube, etc. Which was to be demonstrated.

A, 8. B, 64. C, 512.

SCHOLIUM

The commentators on Euclid bring another demonstration in this place, and indeed a longer one. For after they have shown that C, produced from A into B, is a cube, they infer: [Margin: b — Elem. VIII.12] therefore between B and C, which are cubes, two mean proportionals fall. And since [Margin: c — Elem. VII.17] as B is to C, so is A to B — because A, multiplying A and B, made B and C themselves — [Margin: d — Elem. VIII.8] two mean proportionals will also fall between A and B. And so, [Margin: e — Elem. VIII.23] since B is a cube, A too will be a cube. But our demonstration is shorter and clearer, as is evident.

A, 8. B, 64. C, 512.

THEOR. 7. PROPOS. 7. [Margin: vij.]

If a composite number, multiplying some number, makes another, the product will be a solid number.

Let the composite number A, multiplying any number B, make C. I say that C is a solid number. For since A is composite, [Margin: a — Def. 13] some number besides the unit measures it; let D measure A by E. This being posited, [Margin: b — Ax. 9] with D multiplying E, A will be produced. Since therefore B, multiplying A, made C, C will be generated from the mutual multiplication of the three numbers D, E, B. And accordingly it will be a solid number by the definition, its sides being D, E, B. Wherefore, if a composite number, multiplying some number, etc. Which was to be shown.

A, 6. B, 11. C, 66.
D, 2. E, 3.

THEOR. 8. PROPOS. 8. [Margin: viij.]

If from the unit there are any number of continued proportionals, then the third from the unit is a square, and all that skip one; the fourth is a cube, and all that skip two; and the seventh is at once both a cube and a square, and all that skip five.

Let there be, from the unit, any number of continued proportionals A, B, C, D, E, F, G, H, I, K, L, M. I say that the third, B, from the unit is a square, together with all that skip one — which are D, F, H, K, M:

Unit. A, 3. B, 9. C, 27. D, 81. E, 243. F, 729. G, 2187.
H, 6561. I, 19683. K, 39049. L, 177147. M, 531441.

(K printed 39049; the $\times 3$ progression requires 59049. See numerical impossibles.)

The fourth, C, is a cube, together with all that skip two — of which sort are F, I, M; and the seventh, F, is at once a cube and a square, together with all that skip five — namely M.

For since the unit is to A as A is to B, [Margin: a — Ax. 5] the unit measures A equally as A measures B; but the unit measures A by A. [Margin: b — Ax. 9] And so A, multiplying A, will produce B. Therefore B is a square. And since B, C, D are three successive proportionals, and B is a square, [Margin: c — Elem. VIII.22 [?]] D too will be a square. By the same reasoning, taking the three successive proportionals D, E, F, since D is a square, [Margin: d — Elem. VIII.22] F too will be a square — and likewise all that skip one.

Again, since the unit is to A as B is to C, the unit measures A equally as B measures C. [Margin: e — Ax. 5] But the unit measures A by A. Therefore B will also measure C by A, [Margin: f — Ax. 9] and so B, multiplying A, will produce the number C. Wherefore, since A multiplying itself makes B, and multiplying B makes C — as has been shown — C is a cube. And since C, D, E, F are four successive proportionals, and C is a cube, [Margin: g — Elem. VIII.23] F too will be a cube. By the same argument, taking the four successive proportionals F, G, H, I, since F is a cube, [Margin: h — Elem. VIII.23] I too will be a cube — and so all that skip two.

Finally, since F, the seventh from the unit, has been shown to be both a square and a cube, it will be at once cube and square. And in the same way M, the seventh from F — five being skipped, namely G, H, I, K, L — will be at once cube and square; and likewise all that skip five. If therefore from the unit there are any number of continued proportionals, etc. Which was to be demonstrated.

SCHOLIUM

This theorem can also be proposed in this way:

If there are any number of continued proportionals from the unit, then all those set in odd places — namely in the third, fifth, seventh, ninth, eleventh, and so on — are squares. All those, however, that immediately follow the numbers set in the places third, sixth, ninth, twelfth, fifteenth, eighteenth, and the others that three measures — of which sort are the fourth, seventh, tenth, thirteenth, sixteenth, nineteenth, and so on — are cubes. And all those that immediately follow the numbers set in the places sixth, twelfth, eighteenth, twenty-fourth, and the others that six measures — such as the seventh, thirteenth, nineteenth, twenty-fifth, and so on — are at once cubes and squares.

For the numbers of the first order always skip one after the third from the unit; the numbers of the second order always omit two numbers after the fourth from the unit; and finally the numbers of the third order always interpose five after the seventh from the unit, just as Euclid proposes in the theorem.

THEOR. 9. PROPOS. 9. [Margin: ix.]

If from the unit there are any number of continued proportionals, and the one right after the unit is a square, then all the rest will be squares too. But if the one after the unit is a cube, then all the rest will be cubes too.

Let there be, from the unit, any number of continued proportionals A, B, C, D, E, F, and let the first, A, next to the unit, be a square. I say that all the rest too are squares. That the third from the unit, and all that skip one — which are B, D, F — are squares, [Margin: a — Elem. IX.8] has already been demonstrated. That the remaining intermediate ones, C and E, are also squares will become clear thus. Since A, B, C are three continued proportionals, and A is a square, [Margin: b — Elem. VIII.22] C too will be a square. And in the same way, taking the three continued proportionals C, D, E, since C is a square, [Margin: c — Elem. VIII.22] E too will be a square. Therefore all of A, B, C, D, E, F are squares. We shall show the same if more numbers are in continued proportion.

Unit. A, 4. B, 16. C, 64. D, 256. E, 1024. F, 4096.

Now let A, next to the unit, be a cube. I say that the rest too are cubes. That the fourth from the unit, and all that skip two — of which sort are C and F — are cubes, [Margin: d — Elem. IX.8] has already been demonstrated. That the remaining ones B, D, E are cubes we shall show thus.

Unit. A, 8. B, 64. C, 512. D, 4096. E, 32768. F, 262144.

Since the unit is to A as A is to B, the unit measures A equally as A measures B. [Margin: e — Ax. 5] But the unit measures A by A itself. Therefore A too will measure B by itself; [Margin: f — Ax. 9] and so the cube A, multiplying itself, will produce the number B. [Margin: g — Elem. IX.3] Wherefore B is a cube. And since A, B, C, D are four continued proportionals, and A is a cube, [Margin: h — Elem. VIII.23] D too will be a cube. And by the same reasoning, taking the four successive proportionals B, C, D, E, since B is a cube, [Margin: i — Elem. VIII.23] E too will be a cube. Therefore all of A, B, C, D, E, F are cubes. In no other way shall we demonstrate that all are cubes, if more are in continued proportion. And so, if from the unit there are any number of continued proportionals, etc. Which was to be demonstrated.

SCHOLIUM

The Geometer [Euclid] did not demonstrate that, if the number after the unit is at once a cube and a square, the rest too are all at once cubes and squares — because this very thing is plainly gathered from what has been demonstrated. For if the one next to the unit is at once a cube and a square, then in the respect in which it is a cube, all the rest will by that account be cubes; and in the respect in which it is a square, all the rest too will by that account be squares, as has been demonstrated. Therefore all will be at once cubes and squares.

But the whole proposition can be more easily demonstrated in this way. Let A, next to the unit, be first a square. I say that all are squares. For since, by the scholium to Proposition 10 of Book VIII, A multiplying itself makes B, B will by definition be a square. Likewise,

Unit. A, 4. B, 16. C, 64. D, 256. E, 1024. F, 4096.

since, by the same scholium, A multiplying B makes C, and A and B are squares, C too will be a square, by the scholium to Proposition 2 of this book. Again, since by the same scholium to Proposition 10 of Book VIII, A multiplying C makes D, and A and C are squares, D too will be a square, by the same scholium to Proposition 2 of this book. And so on in succession: since by that scholium to Proposition 10 of Book VIII, A multiplying D produces E, and multiplying E makes F, and so forth.

Let A, next to the unit, then be a cube. I say that all are cubes. For since, by the scholium to Proposition 10 of Book VIII, the cube A multiplying itself makes B, [Margin: k — Elem. IX.3] B too will be a cube. Likewise, since by the same scholium A multiplying B makes C, and A and B are cubes, [Margin: l — Elem. IX.4] C too will be a cube. Again, since by the same scholium A multiplying C makes D, and A and C are cubes, [Margin: m — Elem. IX.4] D too will be a cube. And so with the rest, since by that scholium A multiplying D generates E, and multiplying E produces F, and so forth.

Unit. A, 8. B, 64. C, 512. D, 4096. E, 32768. F, 262144.

THEOR. 10. PROPOS. 10. [Margin: x.]

If from the unit there are any number of continued proportionals, and the one after the unit is not a square, then no other will be a square either, except the third from the unit and all that skip one. But if the one after the unit is not a cube, then no other will be a cube either, except the fourth from the unit and all that skip two.

Let there be, from the unit, any number of continued proportionals A, B, C, D, E, F, G, H, I, and so on, and let the first, A, next to the unit, not be a square. I say that no other is a square either, except the third from the unit and all that skip one — that is, except B, D, F, H, and so on. For if, besides these, some other is a square, let it be a square:

Unit. A, 2. B, 4. C, 8. D, 16. E, 32. F, 64. G, 128. H, 256.
I, 512. K, 1024. L, 2048. M, 4096.

[Margin: a — Elem. IX.8] Since, then, D too is a square, and since as D is to E, or E is to F, so is A to B — and, conversely, as E is to D, or F is to E, so is B to A — B will

have to A the ratio that the square number E has to the square number D, or the square F to the square E. [Margin: b — Elem. IX.8] But B, the third from the unit, is a square. [Margin: c — Elem. VIII.24] Therefore A too, the first from the unit, will be a square; which is absurd, for A is posited as not a square. Therefore E is not a square. By the same reasoning we shall show that no other besides those named is a square.

But now let A, next to the unit, not be a cube. I say that no other is a cube either, except the fourth from the unit and all that skip two — namely, except C, F, I, and so on. For if, besides these, some other can be a cube, let it be D, ...let it be D, a cube. [Margin: d — IX.8] Since, then, F too is a cube, and since, *ex aequali*, as D is to F, so A is to C (because the three numbers D, E, F have the same ratio as the three A, B, C), then by inversion, as F is to D, so C is to A; and so C will bear to A the ratio that the cube F bears to the cube D. [Margin: e — IX.8] But C is a cube, since it is the fourth from the unit. [Margin: f — VIII.25] Therefore A also, the first from the unit, will be a cube. And this contradicts the hypothesis. So D is not a cube.

And should E be believed to be a cube: [Margin: g — IX.8] since C too is a cube, and, *ex aequali*, as the cube C is to the cube E, so A is to C, then by inversion, as the cube E is to the cube C, so C is to A; and since C is a cube, [Margin: h — VIII.25] A will be a cube as well — which is not supposed. So E is not a cube.

And just as it was shown that the two numbers D and E lying between the two cubes C and F are not cubes, so by the same reasoning we shall show that neither G and H, between the cubes F and I, nor any other two numbers lying between two cubes, are cubes. Therefore, if from a unit there be any number of continued proportionals, and so on. Which was to be demonstrated.

SCHOLIUM

It is not necessary that, if the number after the unit is not both a cube and a square, no other should be both a cube and a square except the seventh from the unit and all that skip five; for sometimes the third from the unit, sometimes the fourth, can be both a cube and a square, even though the first from the unit is not both a cube and a square.

For let the first number after the unit, A, be a cube but not also a square. I say that B, the third, is both a cube and a square: a cube, [Margin: i — IX.9] because, the first being a cube, all are cubes; a square, [Margin: k — IX.8] because it is the third from the unit.

Unit. A, 8. B, 64.

Next, let A after the unit be a square but not also a cube. I say that the fourth, C, is both a cube and a square: [Margin: l — IX.8] a cube, because it is the fourth from the unit; [Margin: m — IX.9] a square, because, the first being a square, all are squares.

Unit. A, 4. B, 16. C, 64.

Finally, let A after the unit be neither a cube nor a square. I say that no other is both a cube and a square except the seventh, F, and all that skip five. For, the first not being a square, [Margin: n — IX.10] no other is a square except the third from the unit and all that skip one — of the kind we taught in the scholium to Proposition 8 of this book, namely the third, fifth, seventh, ninth, eleventh, thirteenth, fifteenth, seventeenth, nineteenth, and so on. And the first not being a cube, [Margin: o — IX.10] no other is a cube except the fourth from the unit and all that skip two — such as, as appears from the same scholium, the fourth, seventh, tenth, thirteenth, sixteenth, nineteenth, and so on. It is therefore clear that only the seventh, the thirteenth, and the nineteenth — all of which skip five — are at once squares and cubes, and so on for the rest. For only into these places do a square and a cube fall together, as is plainly evident to anyone who has rightly weighed this proposition and the eighth of this book.

Unit. A, 6. B, 36. C, 216. D, 1296. E, 7776. F, 46656.

THEOR. 11. PROPOS. 11.

[Margin: xj.]

If from a unit there be any number of continued proportionals, the less measures the greater by one of the numbers that are among the proportionals.

Let there be from a unit any number of continued proportionals, A, B, C, D, E, F, G. I say that any of the smaller ones, say C, measures any of the greater, say G, by one of the numbers A, B, C, D, E, F, G. For since, *ex aequali*, as C is to G, so the unit is to D

Unit. A, 3. B, 9. C, 27. D, 81. E, 243. F, 729. G, 2187.

(because the five numbers C, D, E, F, G have the same continuous ratio as the unit and the four numbers A, B, C, D), [Margin: a — Def. 20] the unit measures the number D just as the number C measures the number G. [Margin: b — Axiom 5] But the unit measures the number D by D itself. Therefore C too, the number, will

measure the number G by D. By the same reasoning E will measure F by A, since as E is to F, so is the unit to A, and so on. So likewise A will measure G by F, since, *ex aequali*, as A is to G, so the unit is to F, and so on. And so with the rest in the same way. Therefore, if from a unit there be any number of continued proportionals, and so on. Which was to be shown.

SCHOLIUM

It is moreover plain from this that, by however much the greater number is distant from the greater measuring number, by so much is the number distant from the unit by which the less measures the greater; because the ratio of the less to the greater ought to be the same as that

Unit. A, 3. B, 9. C, 27. D, 81. E, 243. F, 729. G, 2187.

of the unit to the number by which the less measures the greater, as appears from the demonstration. And so B will measure F by D; and C will measure F by C, that is, by itself, and so on — because between B and F, just as between the unit and D, three numbers are interposed; and between C and F, just as between the unit and C, two numbers lie between.

[Margin: c — IX.9] From this, again, it results that any number that multiplies itself produces a number which, among the proportionals, is as far distant from it as it is itself from the unit; but if some smaller number multiplies a greater one, there is produced a number which is as far distant from the greater as the smaller is from the unit — because, if a number measuring a number multiplies the one it measures, the number that is measured is produced. So C, multiplying itself, will beget F, since F is as far from C as C is from the unit; and therefore C measures F by C, as we said. So likewise B, multiplying D, will make the same F; so that D measures F by B, and so on with the rest.

THEOR. 12. PROPOS. 12.

[Margin: xij.]

If from a unit there be any number of continued proportionals, then whatever prime numbers measure the last, these also measure the one that is nearest to the unit.

Let there be from a unit any number of continued proportionals, A, B, C, D. I say that whatever prime numbers measure the last, D, measure also A, the one nearest the unit. For let the prime number E measure D. I say that this same E, a prime, also measures the number A, nearest the unit. For if it does not measure A,

[Margin: a — VII.31] then E, being prime, will be prime to A: that is, A and E will be prime to one another. Let E measure D by F, [Margin: b — IX.9] so that E, multiplying F, makes D. But since A too measures D by C — and so A, multiplying C, makes D, as we showed in the scholium to the preceding proposition — the same number D will be produced from A, the first, into C, the fourth, and from E, the second, into F, the third. [Margin: c — VII.19] Therefore, as A, the first, is to E, the second, so F, the third, is to C, the fourth. [Margin: d — VII.23] Since, then, A and E are prime to one another, [Margin: e — VII.21] and hence least in their ratio, [Margin: f — IX.9] A will measure F just as E measures C. Let E measure C by G, so that E, multiplying G, makes C. But since A too, by the same scholium of the preceding proposition, measures C by B, [Margin: g — IX.9] so that A, multiplying B, makes C, the same number C will be procreated from A, the first, into B, the fourth, and from E, the second, into G, the third. [Margin: h — VII.19] Therefore, as A, the first, is to E, the second,

Unit. A, 10. B, 100. C, 1000. D, 10000. E, 5. H, 20. G, 200. F, 2000.

so is G, the third, to B, the fourth. Wherefore, since A and E are prime to one another, [Margin: i — VII.23] and therefore least in their ratio, [Margin: k — VII.21] A will measure G just as E measures B. Let E measure B by H, [Margin: l — Axiom 6] so that E, multiplying H, makes B. But A too measures B by A, and therefore A, multiplying itself, makes B, as appears from the same scholium of the preceding proposition. So the same number B is begotten from E, the first, into H, the third, and from A, the middle, into itself. [Margin: m — Def. 20] Therefore, as E, the first, is to A, the second, so A, the second, is to H, the third. Since, then, E and A are prime to one another, [Margin: n — VII.23] and hence least in their ratio, [Margin: o — VII.21] E will measure A just as A measures H. But this contradicts the hypothesis, for E was supposed not to measure A. Therefore it is false that E does not measure A. For from the very supposition that E is said not to measure A, it will always be demonstrated that E does measure A — which is absurd. Therefore E measures A. By the same argument we shall show that whatever other prime numbers measure D also measure A; and the reasoning will be the same if C or B be set as the last number.

Another way. [Margin: p — VII.31] Let the prime number E measure the last, D. I say that E measures A as well. For if it does not measure it, E will be prime to A. Since, then, A and E are prime to one another, and A, multiplying itself, makes B, as is established from the scholium of the preceding proposition, [Margin: q — VII.27] B will be prime to E. And since A and B are prime to E, while C is made from A into B, by the same scholium of the preceding proposition, [Margin: r — VII.26] C will be prime to E. Again in the same way, since A and C are prime to E,

and D is made from A into C, by the same scholium of the preceding proposition, [Margin: s — VII.26] D will be prime to E. Therefore E does not measure D — which contradicts the hypothesis. Therefore E measures A.

Unit. A, 6. B, 36. C, 216. D, 1296. E, 3.

Therefore, if from a unit there be any number of continued proportionals, and so on. Which was to be shown.

COROLLARIUM

And so neither any prime number greater than the one nearest the unit, nor any smaller one that does not measure the one nearest the unit, can measure the last. For if it measured the last, it would also measure the one nearest the unit, as has been demonstrated — which is not supposed.

SCHOLIUM

The demonstration of this first proposition is admirable. For in it Euclid, from the fact that E is said *not* to measure A, shows by an affirmative demonstration that E *does* measure A — which seems impossible to be done. For if someone were to set out to demonstrate that Socrates is white from the fact that he is not white, he would seem to bring forward something paradoxical and unexpected. Yet something not unlike this is what Euclid has done here with numbers, and in several other propositions that follow. Cardano [Cardanus] too effected something similar with magnitudes, in Book 5 of his *De proportionibus*, Proposition 201, and boasts that he was the first of all to discover this manner of demonstrating — which I think he would not have said, had he weighed more carefully the force of this demonstration, or at least, if he did weigh it, had he recalled it to memory; since Euclid, long before him, used this very mode of demonstrating, as is manifest from this twelfth theorem. Theodosius too used the same kind of demonstration in Book 1 of the *Spherics*, Proposition 12, as we noted there.

[Margin: t — IX.12] Furthermore, from what has been demonstrated it is clear that whatever prime number measures the last also measures all the others before it. For since it measures the one nearest the unit, and this one measures all that follow, [Margin: u — IX.11] because the less always measures the greater by one of the numbers that are among the proportionals, [Margin: x — Axiom 11] it is manifest that it measures them all.

THEOR. 13. PROPOS. 13.

[Margin: xiiij.]

If from a unit there be any number of continued proportionals, and the one after the unit is prime, then no other number will measure the greatest except those that are among the proportionals.

Let there be from a unit any number of continued proportionals, A, B, C, D, of which A, the one nearest the unit, is prime. I say that no other number except A, B, C themselves measures the greatest, D. For if it be possible, let another number E, different from A, B, C, measure D. Now it is manifest that E is not a prime number. For if it were prime and measured the last, D, [Margin: a — IX.12] it would also measure A, nearest the unit, which is supposed prime — which is absurd. Therefore E is not prime, but composite; [Margin: b — VII.33] and so some prime number will measure it. And I say this can be no other than the prime A. For if another prime

Unit. A, 5. B, 25. C, 125. D, 624. [recte: D, 625] E — H — G — F —

than A were to measure E, then, since E measures the last, D, [Margin: c — IX.11] that other prime would also measure the same D, [Margin: d — IX.12] and hence A itself as well, the first, namely the one nearest the unit. Which is absurd. Therefore no prime other than A measures E.

Now let E measure D by F. I say that F is different from A, B, C. For if F were the same as some one of A, B, C, and E measured D by F, then E would measure D by one of A, B, C; [Margin: e — VII.8] and conversely one of A, B, C (namely the one by which E measures D) would measure D by E. [Margin: f — IX.11] Since, then, each of A, B, C measures D by one of A, B, C, E would be the same as some one of A, B, C — which contradicts the hypothesis, for E was supposed *not* the same as any of A, B, C. Therefore F is not the same as any of A, B, C, but different. And since E measures D by F, [Margin: g — VII.8] conversely F measures D by E. But F will not be prime: for if it were prime and measured the last, D, [Margin: h — IX.12] it would also measure A, nearest the unit, which is prime — which is absurd. Therefore F is not prime, but composite; [Margin: i — VII.33] and so some prime number will measure it. And this again, I say, can be no other than the prime A.

Unit. A, 5. B, 25. C, 125. D, 625. E — H — G — F —

For if a prime other than A were to measure F, then, since F measures the last, D, [Margin: k — IX.11] that other prime would also measure the one nearest the

unit, which is prime — which is absurd. Therefore no prime other than A measures F.

Now since E measures D by F, [Margin: m — IX.9] D is made from E into F; but D is also made from A into C, as we taught in the scholium to Proposition 11 of this book. So the same number D is made from A, the first, into C, the fourth, and from E, the second, into F, the third; [Margin: n — VII.19] and hence, as A, the first, is to E, the second, so F, the third, is to C, the fourth. But A measures E, as was shown. Therefore F too measures C. Let it measure it by G. Since, then, F, different from A and B, measures the last, C (for we now leave aside the number D), by G, we shall show similarly that G is different from A and B, and is not prime but composite, and that only the prime A measures it — just as it was shown of the number F, by which E, different from A, B, C, measured the last, D.

[Margin: o — VII.8] For if G were the same as some one of A, B, and F measured C by G, then F would measure C by one of A, B; and conversely one of A, B (namely the one by which F measures C) would measure C by F. Since, then, each of A, B measures C by one of A, B, F would be the same as some one of A, B — which is absurd, for it was shown that F is not the same as any one of A, B. [Margin: p — VII.11] Therefore G is not the same as any of A, B, but different. And since F measures C by G, [Margin: q — VII.8] conversely G measures C by F. But G will not be prime. For if it were prime and measured the last, C, [Margin: r — IX.12] it would also measure the prime number A, nearest the unit — which is absurd. Therefore G is not prime, but composite; [Margin: s — VII.33] and hence some prime will measure it, and I say that this can be no other than A. For if a prime other than A were to measure G, then, since G measures the last, C, [Margin: t — IX.11] that other prime would also measure the same C, [Margin: u — IX.12] and so A itself as well, nearest the unit, which is prime — which is absurd. Therefore no prime other than A measures G. [Margin: x — IX.9] Now since C is made from F into G — because F measures C by G — while the same C is made from A into B, as we taught in the scholium to Proposition 11 of this book, the same number C is made from A, the first, into B, the fourth, and from F, the second, into G, the third. [Margin: y — VII.19] Therefore, as A, the first, is to F, the second, so G, the third, is to B, the fourth. But A measures F, as was demonstrated. Therefore G too measures B. Let it measure it by H. Since, then, G, different from A, measures the last, B (for we now leave aside the numbers C and D), by H, we shall show similarly that H is different from A, just as it was shown of the numbers F and G.

[Margin: z — IX.9] For if H were the same as A, and G measured B by H, then G would measure B by A; and conversely A would measure B by G. Since, then, A

measures B by A, as is established from the scholium to Proposition 11 of this book, G would be the same as A — which is absurd. For it was shown that G is not the same as A. Therefore H is not the same as A, but different. [Margin: a — IX.9] Now since B is made from G into H — because G measures B by H — while the same B is also made from A into itself, as we taught in the scholium to Proposition 11 of this book, the same number B is made from H, the first, into G, the third, and from A, the middle, into itself. [Margin: b — VII.20] Therefore, as H, the first, is to A, the second, so A, the second, is to G, the third. But A measures G, as has been demonstrated. Therefore H too measures A, a prime number. Which is absurd. Therefore, if A is prime, no number measures the greatest, D, except A, B, C themselves. And hence, if from a unit there be any number of continued proportionals, and so on. Which was to be demonstrated.

THEOR. 14. PROPOS. 14.

[Margin: xiv.]

If prime numbers measure the least number, no other prime number will measure it except those that measured it from the beginning.

Let A be the least number that the prime numbers B, C, D measure. I say that no other prime except B, C, D measures A. For, if it be possible, let another prime number E, different from B, C, D, measure A by the number F.

A B .. C ... D E — F —

Since, then, E measures A by F, [Margin: a — IX.9] E, multiplying F, will make A. [Margin: b — VII.32] Wherefore each of B, C, D will measure one or other of E, F — not indeed E, which is prime and different from them: therefore F, which is smaller than A. Which is absurd. For A was set as the least that the primes B, C, D measure. Therefore, if prime numbers measure the least number, and so on. Which was to be demonstrated.

SCHOLIUM

Campanus adds in this place the following theorem, not useless for what follows. Namely:

If any number of continued proportionals are the least of all having the same ratio with them, then a number measuring one of them will measure also one or other of the two numbers that are taken as least in the same ratio, or else it will be composite with respect to one of them.

SCHOLIUM (Campanus) — demonstration (*continued*)

(The theorem enunciated at the close of the preceding page: "If any number of continued proportionals are the least of all having the same ratio, then a number measuring one of them will measure also one or other of the two numbers taken as least in the same ratio, or else it will be composite with respect to one of them." Its demonstration now follows.)

Let there be any number of continued proportionals A, B, C, D, E, the least in their ratio, in which two least numbers F, G are likewise taken. Let H first measure the first of them, namely A. I say that H also measures either F or G, or at least is composite with respect to one of them.

For suppose H is not prime but composite. [c] Let there be taken, in the same ratio, three least numbers I, K, L, and four M, N, O, P, and so on, until there are as many, less one, as A, B, C, D, E themselves are. [Margin: c — *Elements* VIII.2]

A, 16. B, 24. C, 36. D, 54. E, 81.

M, 8. N, 12. O, 18. P, 27.

I, 4. K, 6. L, 9.

H — F, 2. G, 3.

Now (as is established from the method of producing any number of least terms given in Book VIII, proposition 2) the number A is produced from F into M, and H measures A. Therefore, by the scholium to proposition 32 of Book VII, H will be composite with respect to F or to M. If with respect to F, we have what was proposed. But if with respect to M — which is produced from F into I, as is established from the demonstration of proposition 2 of Book VIII — then, by the scholium to that same proposition 32 of Book VII, H will again be composite with respect to F or to I. If with respect to F, we have what was proposed; but if with respect to I, then, since I is generated from F into itself, H will be composite with respect to F, by the same scholium to proposition 32 of Book VII. And if H should be prime, we shall show in the same way, from proposition 32 of Book VII (but not from its scholium), that it measures F itself.

Next, let H, not being prime, measure the second, B. Since B is produced from F into N, it will be, as before, that H is composite with respect to F or to N. If with respect to F, we have what was proposed; but if with respect to N — which is produced from F into K — then H will in the same way be composite with respect to F or to K. If with respect to F, we have what was proposed; but if with respect to K, then, since K is generated from F into G, H will also be composite with

respect to F or to G. And if H should be prime, we shall demonstrate by the same reasoning, from proposition 32 of Book VII, that it measures either F or G.

Again, let H, not being prime, measure the third, C. Since it is produced from F into O, H will be composite with respect to F or to O. If with respect to F, we have what was proposed; but if with respect to O — which is produced from F into L — then H will be composite with respect to F or to L. If with respect to F, we have what was proposed; but if with respect to L, then, since L is generated from G into itself, H will likewise be composite with respect to G. And if H should be prime, we shall prove in the same way, from proposition 32 of Book VII, that it measures G itself.

Moreover, let H, not being prime, measure the fourth, D. Since it is produced from F into P, H will be composite with respect to F or to P. If with respect to F, we have what was proposed; but if with respect to P — which is produced from G into L — then H will be composite with respect to G or to L. If with respect to G, we have what was proposed; but if with respect to L, since it is produced from G into itself, H will likewise be composite with respect to G. And if H should be prime, we shall show in the same way, from proposition 32 of Book VII, that it measures G itself.

In the same way, if H, not being prime, measures the last, E, we shall show that H is composite with respect to G; and if H should be prime, that it measures G itself. And so, in the remaining cases, the demonstration will always be the same.

Therefore, if H measures the first number A, it will measure F itself, or will be composite with respect to it. If H measures the last, E, it will measure G itself, or will be composite with respect to it. And finally, if H measures any of the others besides the first and the last, it will measure either F itself or G itself, or will be composite with respect to one or the other. This is clear from the demonstration itself.

DEMONSTRATION IN NUMBERS OF THOSE THINGS WHICH EUCLID DEMONSTRATED IN LINES IN THE SECOND BOOK, IN THE FIRST TEN THEOREMS

Since, in order to demonstrate the theorem that follows, Theon [Theon of Alexandria] assumes certain things concerning numbers which have been demonstrated concerning lines in the second book — just as if the same had been shown of numbers — we have thought it not foreign to our purpose to demonstrate here, of numbers, some of those things which Euclid demonstrated

geometrically of lines in Book II. The same, it is reported by some, was done also by the monk Barlaam [Barlaam of Seminara]. We shall follow the same order which we observe Euclid to have kept in the second book.

I.

If there be two numbers, and one of them be cut into any number of parts: the plane number contained by those two numbers is equal to the numbers contained by the undivided number and each of the parts of the divided number.

Let there be two numbers AB and C, of which AB is divided into AD, DE, EB. Let F be produced from C into AB; likewise GH from C into AD; HI from C into DE; and IK from C into EB.

A . . . D . . E . B C . .
 F
 G H . . . I . . K

I say that F is equal to the numbers GH, HI, IK — that is, to the whole number GK composed of GH, HI, IK. For since C, multiplying AB, produced F, [a] AB measures F by C; that is, AB is a part of F, denominated by C. [Margin: a — 2. pronunc. (Axiom 2)] By the same reasoning, AD is a part of GH, DE of HI, and EB of IK, a part denominated by C — namely, the same part that AB is of F. But since, by what we demonstrated at proposition 5 of Book VII, the whole AB is the same part of the whole GK as AD is of GH, the whole AB will also be the same part of the whole GK as it is of F. [b] And therefore F and GK will be equal to one another. [Margin: b — 4. pronunc. (Axiom 4)] Which was what was proposed.

II.

If a number be divided into two parts: the plane numbers contained by the whole and each of the parts are together equal to the square number produced from the whole.

Let the number AB be divided into AC, CB. I say that the numbers produced from the whole AB into the parts AC, CB are together equal to the square number produced from the whole AB.

D
 A C . . B

For, taking a number D equal to AB, then by theorem 1 the number produced from D — that is, from AB into AB, namely the square of AB — is equal to the

numbers produced from D, that is, from AB, into AC and into CB. Which was what was proposed.

The same will be demonstrated if AB is cut into more parts than two, as can be seen from the second figure appended. For by the same reasoning the number produced from E — that is, from AB, namely the square of AB — is equal to the numbers generated from E, that is, from AB, into the several parts AC, CD, DB.

E
A . . . C . . D . B

III.

If a number be divided into two parts: the plane number contained by the whole and one of the parts is equal both to the number contained by the two parts, and to the square of the said part.

Let the number AB be divided into AC, CB. I say that the number produced from the whole AB into the part AC is equal to that contained by the parts AC, BC, together with the square of the said part AC.

D
A C B

For, taking a number D equal to the said part AC, then by theorem 1 the number produced from D — that is, from AC into AB, or (what is the same) from AB into AC — is equal to the numbers produced from D, that is, from AC into CB, and from D, that is, from AC into AC, namely the square of AC. Which was what was proposed.

IV.

If a number be divided into two parts: the square produced from the whole is equal to the squares produced from the parts, together with the plane number contained twice by the parts.

Let the number AB be divided into AC, CB. I say that the square number produced from AB is equal to the squares of the parts AC, CB, together with the number produced twice from the part AC into the part CB.

A C B

For by theorem 2 the square number of AB is equal to the numbers produced from AB into AC and into CB. But the number produced from AB into AC is, by theorem 3, equal to the number generated from AC into CB, together with the square of AC. Likewise the number produced from AB into CB is, in the same way,

equal to the number produced from AC into CB, together with the square of CB. Therefore the square number produced from AB is also equal to the square numbers of the parts AC, CB, together with the number produced twice from AC into CB. Which was what was proposed.

V.

If a number be cut into two equal and into two unequal parts: the plane number contained by the unequal parts, together with the square number of the number lying between the two sections, is equal to the square produced from the half.

Let the number AB be cut into equal parts AC, CB, and into unequal parts AD, DB. I say that the number contained by the unequal parts AD, DB, together with the square of the intermediate number CD — which is indeed the excess between the half AC (or CB) and one or other of the unequal parts AD, DB — is equal to the square produced from the half number CB.

A C . . . D . . B

For, since the square number of CB is, by theorem 4, equal to the squares of the parts CD, DB, together with the plane number contained twice by CD, DB; and since the number contained once by CD, DB, together with the square of DB, is equal (by theorem 3) to the number produced from CB into DB — let there be taken, in place of the square of DB together with the number produced from CD into DB, the equivalent: then the square number of CB is also equal to the remaining square of CD, together with the number produced from CD into DB. But by theorem 1 the number produced from the whole AD into DB is equal to the numbers produced from CD into DB and from AC into DB. Therefore the square of CB will be equal to the square of CD together with the number produced from AD into DB; that is, the number produced from AD into DB, together with the square of CD, will be equal to the square of CB. Which was what was proposed.

VI.

If a number be divided into two equal parts, and some other number be added to it: the number produced from the whole-with-the-addition into the added part, together with the square of the half number, is equal to the square of the number composed of the half and the added part.

Let the number AB be cut into equal parts AC, CB, and let the number BD be added to it. I say that the number produced from the whole AB together with the added BD, taken as one — namely from AD — into the added part BD, together

with the square of the half number CB, is equal to the square produced from CB, the half, together with the added BD, taken as one; that is, to the square of CD.

A C B . . . D

For, since the square of CD is, by theorem 4, equal to the squares of the parts CB, BD, together with the number contained twice by them, CB, BD — that is, equal to the squares of the parts CB, BD, together with the numbers contained by CB, BD and by AC, BD; and since the number contained by AD into BD is (by theorem 1) equal to the numbers contained by CB, BD, by AC, BD, and by BD, BD — that is, together with the square of BD — it follows that, if this number produced from AD into BD be taken in place of the square of the part BD together with the numbers produced from CB into BD and from AC into BD, the square of CD is also equal to the remaining square of CB, together with the number produced from AD into BD; that is, the number produced from AD into BD, together with the square of CB, is equal to the square of CD. Which was what was proposed.

VII.

If a number be divided into two parts: the square of the whole, together with the square of one of the parts, is equal to twice the number produced from the whole into that part, together with the square of the remaining part.

Let the number AB be divided into the parts AC, CB. I say that the square of the whole AB, together with the square of the part CB, is equal to twice the number produced from the whole AB into the said part CB, together with the square of the remaining part AC.

A C B

For since, by theorem 4, the square of the whole AB is equal to the squares of the parts AC, CB, together with the number produced twice from AC into CB: if the square of CB be added in common, the squares of the numbers AB, CB together will be equal to the squares of the numbers AC, CB, CB, together with the number produced twice from AC into CB.

But to that which is produced twice from AC into CB, together with the square of CB taken twice, there is equal (by theorem 3) the number produced twice from AB into CB. Therefore, if in place of the number produced twice from AC into CB together with twice the square of CB, there be taken the number produced twice from AB into CB, the squares of the numbers AB, CB together will be equal to the

number produced twice from AB into CB, together with the square of the remaining part AC. Which was what was proposed.

VIII.

If a number be divided into two parts: four times the number produced from the whole into one of the parts, together with the square of the remaining part, is equal to the square of the number composed of the whole and the aforesaid part.

Let the number AB be cut into the parts AC, CB. I say that the number produced four times from the whole AB into the part CB, together with the square of the remaining part AC, is equal to the square of the number composed of the whole AB and the aforesaid part CB.

A C . . . B . . . D

For, adding the number BD, which is equal to the said part CB: since the square of the whole AD, composed of AB and BD (that is, the said part CB), is equal (by theorem 4) to the squares of the numbers AB, BD, together with the number produced twice from AB into BD — that is, that which is produced twice from AB into CB; and since (by theorem 7) the squares of the numbers AB, CB together are equal to the number contained twice by AB, CB, together with the square of the number AC — it follows that, if in place of the squares of the numbers AB, CB together with the square of AC there be taken the number produced twice from AB into CB, then the square produced from AD is equal to the number produced four times from AB into CB, together with the square of the remaining part AC. Which was what was proposed.

IX.

If a number be cut into two equal and into two unequal parts: the squares produced from the unequal parts are double the squares produced from the half number and from the intermediate number.

Let the number AB be divided into equal parts AC, CB, and into unequal parts AD, DB. I say that the squares of the unequal parts AD, DB are double the squares produced from AC, the half, and from CD, the intermediate number — which CD is indeed the excess between the half AC (or CB) and one or other of the unequal parts AD, DB.

A C . . . D . . B

For, since the square of the number AD is equal (by theorem 4) to the squares of the numbers AC, CD, together with the number produced twice from AC into CD: if the square of the part DB be added in common, the squares of the parts AD, DB will be equal to the squares of the parts AC, CD, DB, together with the number produced twice from AC — that is, from CB — into CD. But to the square of DB, together with the number produced twice from CB into CD, there are equal (by theorem 7) the squares produced from CB, that is, from AC and CD. Therefore, if in place of the square of DB together with that which is produced twice from CB into CD there be taken the squares of AC, CD themselves, the squares of the parts AD, DB will be equal to the squares of the parts AC, CD taken twice; and therefore the squares of the parts AD, DB are double the squares produced from the parts AC, CD. Which was what was proposed.

X.

If a number be divided into two equal parts, and some other number be added to it: the square of the number composed of the whole and the added part, and the square of the added number, together are double both the square produced from the half, and the square of the number composed of the half and the added part.

Let the number AB be divided into two equal parts AC, DB [recte: CB], and let the number BD be added to it. I say that the square of the number AD, composed of the whole AB and the added BD, and the square of the added number BD, both together, are double the squares produced from AC, the half, and from CD, composed of CB, the half, and the added BD.

A C B . . D

For, since the square of AD is equal (by theorem 4) to the squares of the parts AC, CD, together with the number produced twice from AC — that is, from CB — into CD: if the square of the part BD be added in common, the squares of the numbers AD, BD will be equal to the squares of the parts AC, CD, BD, together with the number produced twice from CB into CD. But (by theorem 7) to the square of BD, together with the number produced twice from CB into CD, there are equal the squares of the numbers CB, CD; and to the square of CB there is equal the square of AC. Therefore, if in place of the square of BD together with the number produced twice from CB into CD there be taken the squares of the numbers CB, CD — that is, of the numbers AC, CD — the squares of the numbers AD, BD will be equal to the squares of the numbers AC, CD taken twice; and therefore the squares of the numbers AD, BD are double the squares produced from AC, CD. Which was what was proposed.

Now we shall demonstrate that theorem 11 of Book II cannot be accommodated to numbers — that is, that it is in no way possible for any number to be divided into two parts such that the plane number produced from the whole into one of the parts is equal to the square of the remaining part — as we noted there.

Let the number AB, if it be possible, be divided at C, so that the number produced from the whole AB into the part CB is equal to the square of the remaining part AC.

A D E C B

Now, since the number contained by the extremes AB, CB is equal to the square of the mean number AC, [a] it will be, as AB is to AC, so AC to CB. [Margin: a — *Elements* VII.20] But AB is greater than AC; therefore AC too is greater than CB. Now let CD, equal to CB, be taken away: then it will also be, as AB is to AC, so AC to CD. Since therefore the whole AB is to the whole AC as AC — taken away from the whole AB — is to CD, taken away from the whole AC, [b] it will also be, as the whole AB is to the whole AC [Margin: b — *Elements* VII.11], or as the subtracted AC is to the subtracted CD, so CB (the remainder from AB, that is, CD, equal to CB) is to AD, the remainder from AC. And since it is, as AC to CD, so CD to AD, and AC is greater than CD, CD too will be greater than AD. Let DE, equal to AD, be taken away: then it will also be, as AC to CD, so CD to DE. And so, since it is, as the whole AC to the whole CD, so CD — taken away from the whole AC — to DE, taken away from the whole CD, [c] it will also be, as the whole AC is to the whole CD [Margin: c — *Elements* VII.11], or as the subtracted CD is to the subtracted DE, so AD (the remainder from AC, that is, DE, equal to AD) is to EC, the remainder from CD. Therefore, since it is, as CD to DE, so DE to EC, and CD is greater than DE, DE too will be greater than EC. And accordingly a number equal to EC can be taken away from ED; and so on, without any end ever coming to this subtraction.

— which is absurd, since a number cannot be divided to infinity. Therefore the number AB will not be divided in such a way that the plane number produced from the whole multiplied into one of its parts is equal to the square of the remaining part. Which is what was proposed.

Alternatively [Aliter]. The number AB is divided at C in such a way that the product of AB into CB is equal to the square of the remaining part AC. Hence four times the product of AB into CB will be four times the square of AC; and consequently four times AB into CB, together with the square of AC, will be five times the square of the part AC. But the number contained four times under AB and CB, together with the square of AC, is itself a square number, since it is equal

to the square of the number compounded of AB and CB, by the third theorem [of the preceding scholium]. Therefore two square numbers — namely the one contained four times under AB, CB together with the square of AC, and the square of AC itself — have to one another the ratio of 5 to 1, or of 25 to 5. This is absurd, as is clear from the corollary to VIII.24 [coroll. propos. 24. lib. 8]. Therefore the number AB is not divided at C in such a way that the product of AB into CB is equal to the square of AC. Which is what was proposed.

The line divided at C:

A—————C——B

But we shall demonstrate this same thing more clearly at Proposition 29 of this book [ad propos. 29. huius lib.].

THEOR. 15. PROPOS. 15.

[Margin: xvj.]

If three numbers in continued proportion are the least of all those having the same ratio as they, then any two of them added together will be prime to the remaining one.

Demonstration. Let A, B, C be three numbers, the least of all having the same ratio as they. I say that any two of them added together are prime to the remaining one — namely A and B together to C; B and C together to A; and A and C together to B.

Worked values:

A, 9. B, 12.

C, 16.

D, 3. E, 4.

Take two numbers D, E, the least in the same ratio as A, B, C, by the scholium to VII.35 [scholio propos. 35. lib. 7]. Then, from the demonstration of VIII.2 [propos. 2. lib. 8], it is clear that D multiplied into itself makes A; D multiplied into E makes B; and E multiplied into itself makes C. [Margin: a — Elements VII.24] Now since D and E, being the least in their ratio, are prime to one another, [Margin: b — Elements VII.30] each of D, E — and so their sum too — will be prime to the other. And so, since both the sum of D and E, and D itself, are prime to E, [Margin: c — Elements VII.26] the number produced by the sum of D and E multiplied into D is likewise prime to that same E. But the number produced by (D+E) into D is equal, by the third theorem of the preceding scholium, to A (the square of D) together

with B (the product of D and E). Therefore A and B together are prime to E; [Margin: d — Elements VII.27] and consequently they are also prime to C, which is the square of E. So A and B added together are prime to C.

Next, as before, since each of D, E — and so their sum — is prime to the other, [Margin: e — Elements VII.30] it follows (both the sum of D and E, and E itself, being prime to D) [Margin: f — Elements VII.26] that the number produced by the sum of D and E multiplied into E is prime to D. But the number produced by (D+E) into E is equal, by the third theorem of the preceding scholium, to C (the square of E) together with B (the product of D and E). Therefore B and C together are prime to D; [Margin: g — Elements VII.27] and hence also to A itself, which is the square of D. So B and C added together are prime to A.

Second setup (same values, rearranged in the source):

B, 12. C, 16.
A, 9.
D, 3. E, 4.

Finally, as before, since each of D, E — and so their sum — is prime to the other, [Margin: h — Elements VII.30] and conversely each of D, E is prime to the sum of D and E, [Margin: i — Elements VII.26] the product of D into E will also be prime to the sum of D and E; [Margin: k — Elements VII.27] and consequently that same product of D into E will be prime to the sum of D and E multiplied into itself. But the sum of D and E multiplied into itself is equal, by the fourth theorem of the preceding scholium, to the numbers made from D and E each into themselves, together with twice the product of D into E. Therefore the product of D into E is prime to the numbers made from D and E each into themselves and to twice the product of D into E.

Third setup:

A, 9. C, 16.
B, 12.
D, 3. E, 4.

Now, since two numbers taken together — namely the sum of the squares of D and E, and the product of D into E — are prime to one of them, namely to the product of D into E, as has been shown, [Margin: l — Elements VII.20] those two, the sum of the squares of D and E and the product of D into E, will also be prime to one another. Again, since two numbers taken together — the sum of the squares of D and E, and the product of D into E — are prime to one of them, namely to the product of D into E, [Margin: m — Elements VII.30] as has been

shown, those two, the sum of the squares of D and E and the product of D into E, will likewise be prime to one another. Since, then, the squares of D and E make A and C, and the product of D into E makes B, A and C together will be prime to B. And therefore, if three numbers in continued proportion, etc. Which was to be shown.

SCHOLIVM.

Campanus demonstrates this theorem otherwise, and indeed more easily, for any number of numbers whatever in continued proportion, proposing it in the following way:

If any number of numbers in continued proportion are the least of all having the same ratio as they, then all the rest added together are prime to each one of them.

Let there be any number of numbers A, B, C, D in continued proportion, the least [in their ratio]. I say that all the rest added together are prime to each one of them — namely A, B, C together to D; A, B, D together to C; A, C, D together to B; and B, C, D together to A.

Worked values:

A, 8. B, 12. C, 18. D, 27.
E, — F, 2. G, 3. H, —

For if A, B, C together are not prime to D, then A, B, C together and D will be composite to one another, and so some number will measure them as a common measure. Let the number E measure them, if that is possible; and let F and G be taken, the two least in the ratio of the numbers A, B, C, D. Since, then, A, B, C, D are in continued proportion and least, while E measures one of them, namely D, E will also measure one of F, G — or else it will be composite to one of F, G — by the scholium to Proposition 14 of this book [scholio propos. 14. huius libri]. And therefore some number will measure both E and one of F, G.

Let H measure them. And so, since H measures E, and E is supposed to measure the sum of A, B, C and D itself, [Margin: n — Axiom 11] H will also measure that same sum of A, B, C and D itself. But since H measures one of F, G as well — and both F and G measure the middle numbers B, C, by the third corollary to VIII.2 [coroll. 3. propos. 2. lib. 8] — [Margin: o — Axiom 11] H will also measure the middle numbers B, C; [Margin: p — Axiom 10] and on that account the sum of B and C as well. And so, since H measures the whole sum of A, B, C and, when the sum of B and C is subtracted, [Margin: q — Axiom 12] it will also measure the

remainder A. But it was measuring D too. Therefore A and D, the extremes of the least numbers A, B, C, D, are composite to one another. [Margin: r — Elements VIII.3] Yet they are also prime to one another — which cannot be. Therefore the sum of A, B, C and the number D are not composite to one another. So they are prime to one another.

Again, if A, B, D together are not prime to C, then, as before, some number will measure them. Let E measure them, which again, by the scholium to IX.14 [scholio propos. 14. huius lib.], either will measure one of F, G, or will be composite to one of F, G. Let H then measure both E and one of F, G. And so, since H measures E, and E measures the sum of A, B, D, [Margin: s — Axiom 11] H will also measure that same sum of A, B, D. But since H measures one of F, G, which (by the third corollary to VIII.2) measure the middle numbers B, C, [Margin: t — Axiom 11] H will also measure B, C themselves. And so, since H measures the whole sum of A, B, D and, when B is subtracted, [Margin: u — Axiom 12] it will also measure the remaining sum of A, D. And since H measures one of F, G — of which F measures A and G measures D, as is clear from the demonstration of VIII.2 — [Margin: x — Axiom 11] H will also measure one of A, D. [Margin: y — Axiom 12] Therefore it will measure the other too. So A and D, the extremes, are composite to one another. [Margin: z — Elements VIII.3] Yet they are also prime to one another — which cannot be. Therefore A, B, D together are not composite to C. So they are prime to it. Which is what was proposed.

We shall show in no other way that A, C, D together are prime to B, and likewise B, C, D together to A. And the same reasoning holds for any number of numbers whatever in continued proportion.

THEOR. 16. PROPOS. 16.

[Margin: xvij.]

If two numbers are prime to one another, it will not be the case that as the first is to the second, so is the second to any other whatever.

Demonstration. Let A and B be prime to one another. I say that it is not the case that as A is to B, so is B to some other number. For if it were possible, let it be that as A is to B, so is B to another, namely to C. Since, then, A and B are prime to one another, [Margin: a — Elements VII.23] and therefore the least in their ratio, [Margin: b — Elements VII.21] they will equally measure the numbers B and C, which stand in the same ratio — namely A will measure B, and B will measure C. But A also measures itself. Therefore A measures A and B, which are prime to one

another. This is absurd. Therefore it is not the case that as A is to B, so is B to another number C. And by the same reasoning it will not be the case that as B is to A, so is A to another. And so, if two numbers are prime to one another, etc. Which was to be demonstrated.

The magnitudes:

A
 B
 C —————

THEOR. 17. PROPOS. 17.

[Margin: xvii.]

If there are any number of numbers in continued proportion, and their extremes are prime to one another, it will not be the case that as the first is to the second, so is the last to any other whatever.

Demonstration. Let there be any number of numbers A, B, C, D in continued proportion, whose extremes A, D are prime to one another. I say that it is not the case that as A is to B, so is D to some other number. For if it were possible, let it be that as A is to B, so is D to another, namely to E. Then, alternately, it will be that as A is to D, so is B to E. But A and D, being prime to one another, [Margin: a — Elements VII.23] are the least in their ratio. [Margin: b — Elements VII.21] Therefore they will equally measure B and E — namely A will measure B, and D will measure E. But it is the case that as A is to B, so is B to C. So, since A measures B, [Margin: c — Axiom 11] A will on that account also measure C. And since it is the case that as B is to C, so is C to D, and B measures C, C too will measure D. And so, since A measures C, [Margin: d — Axiom 11] it will also measure D. But it measures itself as well. Therefore A measures A and D, which are prime to one another. This is absurd. Therefore it is not the case that as A is to B, so is D to another number E. And by the same argument it will not be the case that as D is to C, so is A to another. And so, if there are any number of numbers in continued proportion, etc. Which was to be shown.

Worked values:

A, 8. B, 12. C, 18. D, 27. E, —

PROBL. 1. PROPOS. 18.

[Margin: xix.]

Given two numbers, to consider whether a third proportional to them can be found.

Demonstration. Let A and B be the two given numbers, and let it be required to consider whether a third proportional to them can be found — that is, whether there is some other number to which B stands as A stands to B. Now either A and B are prime to one another, or they are not. If they are prime to one another, [Margin: a — Elements IX.16] it is clear from what has been demonstrated that a third proportional to them cannot be found.

A, 4. B, 7.

But if A and B are not prime to one another, let B multiplied into itself make C. Then either A measures C, or it does not. First let A measure C, by D. I say that a third proportional to A and B can be found — indeed, that D itself is the third proportional. For since A measures C by D, [Margin: b — Axiom 9] C will be produced from A into D. But by construction the same C is produced from B into itself. Therefore the number contained under the extremes A and D is equal to the number described from the mean B; [Margin: c — Elements VII.20] and consequently it will be that as A is to B, so is B to D. And so D has been found as the third proportional to A and B.

A, 4. B, 6. D, 9. C, 36.

But now let A not measure C. I say that a third proportional to A and B cannot be found. For if it could be found, let D be found, such that A is to B as B is to D. Since, then, it is the case that as A is to B, so is B to D, [Margin: d — Elements VII.20] the number contained under the extremes A, D will be equal to the number produced from the mean B into itself — that is, to C. And so, since C is produced from A into D, [Margin: e — Axiom 7] A will measure C, by D. But A was supposed not to measure it. This is absurd. Therefore

a third proportional to A, B cannot be found when A, the first, does not measure C, the product of B, the second, into itself. By the same method we shall consider whether some other third number can be found for B and A, such that A stands to it as B stands to A. And so, given two numbers, we have considered, etc. Which was to be done.

PROBL. 2. PROPOS. 19.

[Margin: xx.]

Given three numbers, to consider whether a fourth proportional to them can be found.

Demonstration. Let A, B, C be three given numbers, whether in continued proportion or not; and let it be required to consider whether a fourth proportional to them can be found — that is, whether there is some other number to which C stands as A stands to B. Let B multiplied into C make D. Then either A measures D, or it does not. First let A measure D, by E. I say that a fourth proportional to A, B, C can be found — indeed, that E itself is the fourth proportional. For since A measures D by E, [Margin: a — Axiom 9] D will be produced from A into E. But the same D is produced from B into C by construction. Therefore the number contained under the extremes A, E is equal to the number contained under B, C, the second and third; [Margin: b — Elements VII.19] and on that account it will be that as A is to B, so is C to E. And so E has been found as the fourth proportional to A, B, C.

A, 8. B, 12. C, 18. E, 27. D, 216.

A, 4. B, 8. C, 9. E, 18. D, 72.

But now let A not measure D. I say that a fourth proportional to A, B, C cannot be found. For let the fourth proportional E be found, if that is possible, such that as A is to B, so is C to E. Since, then, the four numbers A, B, C, E are proportional, [Margin: c — Elements VII.19] the number contained under the extremes A, E will be equal to the number produced from B, the second, into C, the third — that is, to D. And so, since D is produced from A into E, [Margin: d — Axiom 7] A will measure D, by E. But it is supposed not to measure it. This is absurd. Therefore a fourth proportional to A, B, C cannot be found when A, the first, does not measure D, the product of B, the second, into C, the third. By the same method we shall consider whether some fourth number can be found for C, B, A, such that A stands to it as C stands to B. And so, given three numbers, we have considered whether it can be done, etc. Which was to be done.

A, 4. B, 6. C, 9. E, — D, 54.

A, 3. B, 4. C, 10. E, — D, 40.

SCHOLIVM.

What has been demonstrated in the last four propositions — namely 16, 17, 18, and 19 — must be understood of whole numbers. For if we speak of fractions, a further proportional can be adjoined to any two or three numbers, even though their extremes are prime to one another. For, given two numbers, if the square of the second is divided by the first, a third proportional will be produced. Thus,

given the two numbers 3 and 8: if the square of the second, 8 — namely 64 — is divided by 3, the third proportional $21\frac{1}{3}$ will be found, in this way: 3, 8, $21\frac{1}{3}$. For since, when 64 is divided by 3, the number $21\frac{1}{3}$ results, the number divided, 64, will be reproduced by the multiplication of the quotient $21\frac{1}{3}$ by the divisor 3, as we set out at VII, Definition 15 [ad defin. 15. lib. 7]. Since, then, this same number 64 is made from the mean number 8 [Margin: e — Elements VII.20] multiplied into itself, the numbers 3, 8, $21\frac{1}{3}$ will be in continued proportion.

Given three numbers, if the number generated from the second into the third is divided by the first, a fourth proportional will be produced. Thus, given the three numbers 9, 6, 20: if the number 120, generated from the second into the third, is divided by the first, 9, the fourth proportional $13\frac{1}{3}$ will be found, in this way: 9, 6, 20, $13\frac{1}{3}$. For since, when 120 is divided by 9, $13\frac{1}{3}$ results, the number divided, 120, will be reproduced by the multiplication of the quotient $13\frac{1}{3}$ by the divisor 9, from what we wrote at VII, Definition 15. But this same divided number is made from the second into the third. [Margin: f — Elements VII.19] Therefore the four numbers 9, 6, 20, $13\frac{1}{3}$ are proportional.

From these considerations we shall easily recognize, given any number of numbers in continued proportion, whether another proportional can be adjoined to them. For if, taking the last three, another can be found for them, that same one will be proportional to all of them.

Theon, and those who follow him — among whom is also Federico Commandino [Federicus Commandinus] — dispose of this problem in four cases. For (they say) either the three given numbers are in continued proportion and their extremes are prime to one another; or they are not indeed in continued proportion, but their extremes are prime to one another; or they are in continued proportion, but their extremes are not prime to one another; or, finally, they are neither in continued proportion nor are their extremes prime to one another. Here I cannot sufficiently wonder how it is that these most careful interpreters of Euclid — most vigilant in their other demonstrations — nodded off in demonstrating the second case of this problem, and, as it were forgetting themselves and slackening in their diligence, fell into an error, and no light one. For they say that if three given numbers are not in continued proportion, but their extremes are prime to one another, no fourth proportional can be found for them. This is both false, and the demonstration by which they try to establish it is faulty. For the falsity of the matter appears plainly in these numbers, not in continued proportion, 4, 8, 9, whose extremes 4 and 9 are prime to one another, and to which nonetheless a fourth proportional, 18, can be adjoined. For who does not see that as 4 is to 8, so

is 9 to 18, since in each case the ratio is one-half? The same may be seen in countless other examples, as here: 2, 4, 7, 14; likewise 3, 9, 4, 12; likewise 2, 10, 3, 15; likewise 5, 10, 6, 12; and so on. For in all these numbers the extremes of the first three are prime to one another, and yet a further, fourth proportional is adjoined to them. It is false, therefore, that no fourth proportional can be given for them. And that their demonstration, by which they strive to prove this, is faulty will become clear if we bring the demonstration itself into the open. They reason, then, as follows.

Let there be three numbers A, B, C, not in continued proportion, whose extremes A, C are prime to one another. I say that in no way can a fourth proportional be found for them. For if one can be found, let it be D, such that as A is to B, so is C to D, and as B is to C, so is D to E.

A, 3. B, 6. C, 8. D, 16. E, —

It will then follow, from equality of ratios, that as A is to C, so is C to E. But A and C are prime to one another, [Margin: g — Elements VII.23] and on that account the least [in their ratio]. [Margin: h — Elements VII.21] Therefore they will equally measure C and E — namely A will measure C, and C will measure E. But A also measures itself. Therefore A measures the two numbers A, C, which are prime to one another. This cannot be. Therefore a fourth proportional to A, B, C cannot be found.

This is their demonstration, in which they assume that as B is to C, so is D to some other number, namely to E — a thing they have nowhere demonstrated can be done; indeed, this very point is called into doubt in this problem. For it is no less asked whether a

Euclid, Book IX (Clavius's commentary) — Propositions 20–29, with the *Ex Campano* addendum

(Marginal citations follow Clavius's abbreviations: *N. noni* = Elements Book IX, prop. N; *N. septi*/*N. septim*/*N. sept* = Book VII, prop. N; *N. pron* = the Nth axiom [pronuntiatur]. The outer-margin lowercase-Roman numeral beside each heading is Clavius's proposition tally, which here runs consistently one ahead of the Arabic PROPOS. number.)

[Conclusion of the Scholium to Prop. 19]

whether in the three numbers B, C, D a fourth proportional can be found, than in the three A, B, C — since this holds no more in the one case than in the other. Therefore, since in that place they assume as granted the very thing which here they undertake to prove impossible, it is plainly a case of begging the question (to speak with the logicians) in their demonstration. What is more, whenever four numbers are given proportional but not consecutive, of which the first and third are prime to one another — as A, B, C, D are supposed to be — there is no way that another number can be given to which the fourth stands as the second stands to the third. Yet this is precisely what they assume as granted and proved, since without any proof they demand that a number E be given, to which the fourth D stands as the second B stands to the third C. But that this cannot be done we shall easily demonstrate by the very argument they themselves use.

For let there be four numbers A, B, C, D, proportional but not consecutive, and let A and C — the first and third — be prime to one another. I say it is impossible that D should stand to some other number as B stands to C. For suppose, if it can be done, that as B is to C, so D is to E:

A, 4. B, 12. C, 3. D, 9. E —

Then, *ex aequali*, as A is to C, so is C to E. And so, exactly as they themselves showed, A would measure the two numbers A and C, which are prime to one another. This is absurd. Therefore it cannot be that D is to E as B is to C. Hence, in the demonstration of the second member, Theon and the other interpreters of Euclid who follow him assumed something manifestly false.

The first member, however, they show clearly and openly. For if three numbers are consecutively proportional and their extremes are prime to one another [Margin: d — IX.17], it is clear, from what has been demonstrated, that no fourth proportional to them can be found. The last two members, finally, they dispatch in just the way we ourselves resolved the whole problem.

THEOR. 18. PROPOS. 20. [Margin: xxi.]

Prime numbers are more than any assigned multitude of prime numbers.

Let any number of prime numbers A, B, C be proposed. I say there are more primes than A, B, C. For take the least number DE which A, B, C measure, and add to it a unit EF [Margin: a — VII.38]. Then the whole DF is either prime or not

prime. Let it first be prime. Then A, B, C, and DF are prime numbers, more than the assigned multitude A, B, C.

A, 2. B, 3. C, 5.

30.

D ————— E. F

But now let DF not be prime. Then some prime number will measure it — say G [Margin: b — VII.33]. I say that this prime G is the same as none of A, B, C. For if G were the same as one of A, B, C, it would measure the same DE which they measure. Hence G, measuring the whole DF as well as the subtracted DE, would also measure the remainder EF — that is, the unit [Margin: c — Axiom 11]. This is absurd. Therefore the prime G is not the same as any of A, B, C; and so prime numbers A, B, C, G have been found, more than the assigned multitude of primes A, B, C. And by the same route more will be found than A, B, C, G, if the least number they measure be taken, and so on. Therefore prime numbers are more, etc. Which was to be demonstrated.

A, 3. B, 5. C, 7.

105.

D ————— E. F

53.

G —

SCHOLIVM.

This same theorem could have been proposed in the manner of a problem, thus:

Given any number of prime numbers, to find another prime number different from them.

For if any number of primes A, B, C be proposed, we shall find in the same way another prime different from them — namely DF, if it is prime, or else G, which measures DF. And in the same way we shall find, for four primes, a fifth; for five primes, a sixth; and so on we shall find as many prime numbers as anyone wishes.

THEOR. 19. PROPOS. 21. [Margin: xxii.]

If any number of even numbers be added together, the whole will be even.

Let any number of even numbers AB, BC, CD be added together. I say the whole compound AD is also even. For since AB, BC, CD are even, each will have its own half, by definition. Let E be the half of AB, F of BC, and G of CD. Since, then, as AB is to E, so BC is to F and CD is to G (each being a double ratio), it will also be that

as AB is to E, so is AD to E, F, G together [Margin: a — VII.12]. But AB is the double of E. Therefore the whole AD is likewise the double of the compound of E, F, G; and so AD, having as its half the number compounded of E, F, G, is even, by definition. If, then, any number of even numbers, etc. Which was to be demonstrated.

A..... B.... C..... D
E... F.. G....

THEOR. 20. PROPOS. 22. [Margin: xxij.]

If any number of odd numbers be added together, and their multitude be even, the whole will be even.

Let any number of odd numbers, whose multitude is even, AB, BC, CD, DE, be added together. I say the whole compound AE is even. For since AB, BC, CD, DE are odd, each differs from an even number by a unit, by definition.

A.... B.... C..... D..... E

Hence, a unit being subtracted from each, each of the remainders will be even [Margin: a — IX.21]; and so the compound of them will be even. But the multitude of the subtracted units is also even. Therefore the whole AE, so compounded, will be even [Margin: b — IX.21]. If, then, any number of odd numbers, etc. Which was to be shown.

THEOR. 21. PROPOS. 23. [Margin: xxiv.]

If any number of odd numbers be added together, and their multitude be odd, then the whole too will be odd.

Let any number of odd numbers, whose multitude is odd — AB, BC, CD — be added together. I say the whole compound AD is odd.

A..... B... C..... E. D

For since an odd number differs from an even by a unit, by definition, then, the unit ED being taken from the odd CD, the remainder CE will be even. But AC, compounded of the odds AB, BC — even in multitude — is even [Margin: a — IX.22 [?: printed digit reads 12 or 22; the argument requires IX.22]]. Therefore AE too, compounded of the evens AC, CE, will be even [Margin: b — IX.21]. Hence, the unit ED being added, the whole AD will be odd, since an odd differs from an even by a unit, by definition. If, then, any number of odd numbers, etc. Which was to be shown.

SCHOLIVM.

By the same reasoning, an odd number added to an even number, or to several even numbers, will make an odd number. For, a unit being taken from the odd, the remainder will be even — since by definition an odd differs from an even by a unit. Hence that even remainder, together with another given even, or with several given evens, will make an even [Margin: c — IX.21]; and so, that unit being added back again, the whole will become odd, since it differs from an even by a unit alone. Which is what was proposed.

THEOR. 22. PROPOS. 24. [Margin: xxv.]

If an even number be subtracted from an even number, then the remainder too will be even.

From the even number AB let the even CB be subtracted. I say the remainder AC is also even. For the subtracted even CB is either the half of AB, or greater than half, or less. Let it first be the half.

A C B

Since, then, AC — the other half — is equal to the even CB, AC too will be an even number.

But now let the subtracted even CB be greater or less than the half of AB. Since AB, CB are even numbers, they have their halves, by definition; let DB be the half of AB, and EB the half of CB.

A C . . D . . . E B

Since, then, as AB is to its half DB, so is CB to its half EB, by alternation, as AB is to CB, so is DB to EB; and by division, as AC is to CB, so is DE to EB; and again by alternation, as AC is to DE, so is CB to EB. But CB is the double of EB. Therefore AC too is the double of DE; and hence AC, being bisected (in that DE is its half), is even. If, then, an even number be subtracted from an even number, etc. Which was to be shown.

SCHOLIVM.

We shall demonstrate this proposition more easily by reduction to the impossible, thus. If the remainder AC be called not even but odd, then, the unit AD being subtracted, the remainder DC will be even.

A. D . . . C B

Therefore the compound DB will also be even [Margin: a — IX.21]; and hence, the unit AD being added back, the whole AB will become odd — which is absurd, since it is posited even.

THEOR. 23. PROPOS. 25. [Margin: xxvj.]

If an odd number be subtracted from an even number, then the remainder will be odd.

From the even number AB let the odd CB be subtracted. I say the remainder AC is odd.

A C . D B

For, the unit CD being taken from the odd CB, the remaining number DB becomes even. Since, then, the whole AB is likewise posited even, the remainder AD will also be even [Margin: a — IX.24]. Therefore, the unit CD being removed, the remainder AC will be odd. If, then, an odd number be subtracted from an even number, etc. Which was to be demonstrated.

THEOR. 24. PROPOS. 26. [Margin: xxvij.]

If an odd number be subtracted from an odd number, the remainder will be even.

From the odd number AB let the odd CB be subtracted. I say the remainder AC is even.

A C D . B

For, the unit DB being taken from the odds AB, CB, the remainders AD, CD will be even. Since, then, the even CD is taken from the even AD, the remainder AC will also be even [Margin: b — IX.24]. Hence, if an odd number be subtracted from an odd number, etc. Which was to be demonstrated.

THEOR. 25. PROPOS. 27. [Margin: xxvii.]

If an even number be subtracted from an odd number, the remainder will be odd.

From the odd AB let the even CB be subtracted. I say the remainder AC is odd.

A . D C B

For, the unit AD being taken from the odd AB, the remainder DB will be even; and when the even CB is subtracted from it, the remainder DC too will be even

[Margin: a — IX.24]. And so, the unit AD being added back, AC becomes odd. If, then, an even number be subtracted from an odd number, etc. Which was to be demonstrated.

THEOR. 26. PROPOS. 28. [Margin: xxix.]

If an odd number, multiplying an even number, makes some number, the product will be even.

Let the even number C be made from the odd A into the even B. I say C is even. For since C is made from A into B, C will be composed of as many numbers equal to B as there are units in A. Hence, since B is even, C will be composed of as many evens equal to B as there are units in A; and so it will be even [Margin: a — IX.21]. If, then, an odd number multiplying an even makes some number, etc. Which was to be shown.

A... B....
C.....

SCHOLIVM.

By the same demonstration we shall show this too:

If an even number, multiplying an even number, makes some number, the product will be even.

For again C will be composed of as many evens equal to B as there are units contained in A, etc.

A.. B.....
C.....

COROLLARIVM.

It is also clear from these that an even number multiplied into itself produces an even number — as is evident if the evens A and B be supposed equal.

A... B...
C.....

THEOR. 27. PROPOS. 29. [Margin: xxx.]

If an odd number, multiplying an odd number, makes some number, the product will be odd.

From the odd A into the odd B let C be made. I say C is odd. For since C is made from A into B, C will be composed of as many numbers equal to B as there are units in A. Hence, since both A and B are odd, C will be composed of odds equal to B, whose multitude is odd — namely equal to the multitude of units contained in the odd A. Therefore C is odd [Margin: a — IX.23]. Accordingly, if an odd number multiplying an odd makes some number, etc. Which was to be shown.

A... B...
C.....

COROLLARIVM.

From this it follows that an odd number multiplied into itself begets an odd number — as is clear if the odds A and B be supposed equal.

A... B...
C.....

EX CAMPANO.

An odd number measuring an even number measures it by an even number.

Let the odd A measure the even B by C. I say C is even. For if it were odd, then B, made from the odd A into the odd C, would be odd [Margin: b — IX.29]. This is absurd, since B is posited even. Therefore C is even.

A... C...
B.....

An odd number measuring an odd number measures it by an odd number.

Let the odd A measure the odd B by C. I say C is odd. For if it were even, then B, made from the odd A into the even C, would be even [Margin: b — IX.28]. This is absurd, since B is posited odd. Therefore C is odd.

A... C...
B.....

SCHOLIVM.

From these results we shall also most clearly demonstrate that the eleventh theorem of Book 2 [*Elements* II.11] cannot be adapted to numbers — which we also showed by another route in the scholium to Proposition 14 of this book, having undertaken to demonstrate it more clearly in this place. For let the

number AB be cut, if it can be done, into the parts AC, CB, in such a way that the number made from AB into CB is equal to the square of the remaining part AC. Then either both parts AC, CB are odd; or the greater AC is odd and the lesser CB even; or, conversely, the greater AC is even and the lesser CB odd; or, finally, both parts AC, CB are even.

A ——— C ——— B
D — E —

First, let both parts AC, CB be odd, so that the whole number AB is even [Margin: d — IX.22]. Then the number made from AB into CB is even [Margin: c — IX.28], whereas the number made from AC into itself is odd (by the corollary to Proposition 29 of this book). Since, then, the number generated from AB into CB is posited equal to the one made from AC into itself, an even number will be equal to an odd — which cannot be.

Next, let AC be odd and CB even, so that by the scholium to Proposition 32 [?: reads 32; the parallel case below cites the scholium to Prop. 23] of this book the whole AB is odd. Since, then, the number made from AB into CB is even [Margin: f — IX.28], while the number generated from the odd AC into itself is odd (by the corollary to Proposition 29 of this book), that even number will again be equal to this odd one — which is absurd.

Thirdly, let AC be even and CB odd, so that by the scholium to Proposition 23 of this book the whole AB is odd. Since, then, the number made from the odd AB into the odd CB is odd [Margin: g — IX.29], while the number generated from the even AC into itself is even (by the corollary to Proposition 28 of this book), that odd number will again be equal to this even one — which is absurd.

Fourthly, let both parts AC, CB be even. Then, having found (by the scholium to Proposition 35 of Book 7) the two least numbers D, E in the ratio of AC to CB, D and E will be prime to one another [Margin: h — VII.24]; and hence they will not both be even, but either both odd, or one odd and the other even.

A ——— C ——— B
D — E —

And since, as AC is to CB, so is D to E, then by conversion, as CB is to AC, so is E to D; and by composition, as AB is to AC, so is the whole DE to D [Margin: i — VII.20]. But as AB is to AC, so is AC to CB — since the number made from AB into CB is posited equal to the square of the mean AC. Therefore also, as the whole DE is to D, so is D to E; and hence the number made from the whole DE into E will be equal to the square of D [Margin: k — VII.20]. So the whole number D, E has been

cut into the parts D, E — of which either both are odd, or one is odd and the other even — in such a way that the number made from the whole DE into the part E is equal to the square of the other part D. But this we have just shown cannot happen in the number AB, when both parts AC, CB are either odd, or one odd and the other even. Therefore the proposition is established.

THEOR. 28. PROPOS. 30.

[Margin: xxxiii.]

If an odd number measures an even number, it will also measure its half.

Let the odd A measure the even B. I say that A measures the half of B as well. Let A measure B by C. Then, from what we demonstrated after [Campanus] in the preceding proposition, the number C is even, and so it has a half part. Since A measures B by C, C likewise measures B by A [Margin: a. 8. pro.]; and consequently C is a part of B named after A, as we taught at the 3rd definition of Book 7. Now, as C is to its own half, so is B to its own half; and, alternately, as C is to B, so is the half of C to the half of B. But C is a part of B named after A, as was shown; therefore the half of C will likewise be a part of the half of B, named after the same A. And for that reason A measures the half of B [Margin: b. 40. septi. — Elements VII.40]. So, if an odd number measures an even number, and so on. Which was to be shown.

The lettered segments:

A . . . C
B

THEOR. 29. PROPOS. 31.

[Margin: xxxiv.]

If an odd number is prime to some number, it will also be prime to its double.

Let the odd number A be prime to the number B, whose double is C. I say that A is prime to C as well. For if A and C are not prime to one another, some number will measure them—say D—which will necessarily be odd. For if it were even, then, since it measures the odd A, A would be the product of D (an even number) into the number by which it measures A, and so even [Margin: a. 28. noni — Elements IX.28]. But that is absurd, since A is assumed odd. Therefore D, odd and measuring the even C (for C is even, since it has B as its half), will also measure the number B, its half [Margin: b. 30. noni — Elements IX.30]. But it measures A as

well. Therefore D measures A and B, which are prime to one another. That is absurd. It is not the case, then, that A is not prime to C. Hence it is prime. Consequently, if an odd number is prime to some number, and so on. Which was to be shown.

The lettered segments:

A B
C D –

COROLLARIVM.

It follows from this that an odd number which is prime to some number is prime not only to its double—as Euclid proved—but also to its quadruple, its octuple, its sixteen-fold, and so on, proceeding by continual doubling. For if it is prime to the double, it will also be prime to the quadruple, which is the double of the double [Margin: c. 31. noni — Elements IX.31]; and likewise to the octuple, which is the double of the quadruple; and so forth.

THEOR. 30. PROPOS. 32.

[Margin: xxxv.]

Of the numbers doubled from the binary, each one is even-times-even only.

Let there be any numbers B, C, D, E doubled from the binary A. I say that B, C, D, E are even-times-even only. That they are even-times-even is evident. For, a unit being set out, since A is the binary and B, C, D, E are doubles from the binary, the numbers A, B, C, D, E will be successively proportional from the unit—namely in double proportion. Therefore A measures each of B, C, D, E, and every smaller measures the greater one following it, through some one of A, B, C, D, E [Margin: a. 11. noni — Elements IX.11]; and since these are all even, being doubles from the binary, each of B, C, D, E is measured by an even number through an even number. And for that reason each is even-times-even by definition.

That these same numbers are even-times-even *only* is likewise clearly established. For since A, B, C, D, E are continually proportional from the unit, and A, the number next to the unit, is prime—namely the binary—no other number measures any of them except A, B, C, D, E themselves [Margin: b. 13. noni — Elements IX.13]; and since these are all even, each of them is measured by an even number through an even number only. And for that reason each is even-

times-even only. Therefore, of the numbers doubled from the binary, and so on. Which was to be demonstrated.

Vnitas. A, 2. B, 4. C, 8. D, 16. E, 32.

SCHOLIVM.

Hence, together with the arithmeticians, we shall gather the art by which we may find all numbers that are even-times-even only. For let A, B, C, D, E, F be doubles from the binary, which, by what has here been demonstrated, are all even-times-even only, besides those contained in this series; and so, if the series of numbers doubled from the binary be increased to infinity, all even-times-even numbers are found, with none left out. For if it be possible, let there be some other number G, outside the series of numbers doubled from the binary, even-times-even only, whose half is H. Then H will be an even number. (For if it be called odd, then, since it is the half of G, the binary would measure G by H, an odd number; and so G would be even-times-odd. That is absurd, for it is assumed even-times-even only.) Let its half, again, be I. Then again I will be an even number. (For if it be called odd, since it is the fourth part of G, the even number 4 would measure G by I, an odd number; and on that account G would be even-times-odd. That is absurd, for it is assumed even-times-even only.) And so on, the half will always be an even number, until we come to the unit. Let, then, the half of I be a unit, so that I is the binary. Therefore H and G are doubles from the binary I; and consequently G will be some one of the series A, B, C, D, E, F—but it is assumed not to be. That is absurd. No other number, therefore, is even-times-even only, besides those that are doubles from the binary.

A, 4. B, 8. C, 16. D, 32. E, 64. F, 128.

I — — — — H — — — — G — — — —

THEOR. 31. PROPOS. 33.

[Margin: xxxvj.]

If a number has an odd half, it is even-times-odd only.

Let the number A have an odd half. I say that A is even-times-odd only. That it is even-times-odd becomes evident thus. Since A has an odd half, the binary, an even number, measures A by that odd half. Therefore A, by definition, is even-times-odd. That the same A is even-times-odd *only* we shall demonstrate in this way. Let B be the half of A, and C the binary. If, then, A is not even-times-even only, it will also be even-times-even. Therefore some even number will measure it by an even number. Let D, even, measure it by the even E. Then A is the

product of D into E [Margin: a. 9. pro.]; but the same A is the product of C, the binary, into B, its half. Therefore the number produced from C, the first, into B—the fourth—is equal to that produced from D, the second, into E—the third [Margin: b. 19. sept. — Elements VII.19]; and for that reason, as C is to D, so E is to B. But C, the binary, measures the even D. Therefore E too will measure B—an even number an odd one. That is absurd. Therefore A is not even-times-even. Hence it is even-times-odd only. Wherefore, if a number has an odd half, and so on. Which was to be demonstrated.

The lettered segments:

A

A

B C . .

D — — — — E — — —

SCHOLIVM.

Thus, if the doubles of all odd numbers be taken, there will be found all the numbers that are even-times-odd only. That any of them is even-times-odd only is established by this proposition, since each has an odd half. And that these alone are even-times-odd only will be clear from the following theorem, in which it is demonstrated that all even numbers which are neither doubles from the binary nor have odd halves are both even-times-even and even-times-odd. Since, then, no other even number has an odd half except the doubles of odd numbers, it is manifest that no other besides these is even-times-odd only; but each is either even-times-even only, or certainly both even-times-even and even-times-odd.

Impares 3. 5. 7. 9. 11. 13. 15.

Pariter impares tantum. 6. 10. 14. 18. 22. 26. 30.

THEOR. 32. PROPOS. 34.

[Margin: xxxvij.]

If an even number is neither a double from the binary nor has an odd half: it is both even-times-even and even-times-odd.

Let the even number A be neither a double from the binary nor have an odd half, but an even one. I say that A is both even-times-even and even-times-odd. That it is even-times-even is clear. For, since it has an even half, the binary—an even number—measures it by an even number, namely by its half. Therefore, by definition, it is even-times-even.

That the same A is also even-times-odd we shall show thus. When A is divided in two, and its half again in two, and so on, we shall at length fall upon some odd number. For if we were to fall upon the binary, A would be a double from the binary; but it is assumed not a double. That is absurd. Therefore, since we fall upon an odd number, that odd number will measure A by an even number. For otherwise, if it measured A by an odd number, then—since an odd multiplying an odd makes an odd—A would be the product of that odd into this odd, and so odd [Margin: a. 29. noni — Elements IX.29]. That is absurd, for it is assumed even. So, since an odd number measures A by an even, and hence, conversely, an even by an odd, A will, by definition, be even-times-odd. But it was also even-times-even. Therefore it is both even-times-even and even-times-odd. If, then, an even number is neither a double from the binary, and so on. Which was to be shown.

A

SCHOLIVM I.

Easily, from these, we shall find all numbers that are both even-times-even and even-times-odd. For, setting aside all those that are doubles from the binary, and all those that have odd halves, all the other even numbers will, by this proposition, be both even-times-even and even-times-odd.

Furthermore, from the last three theorems, what we wrote at the 9th definition of Book 7 is plainly understood.

THEOR. 33. PROPOS. 35.

[Margin: xxxviii.]

If there are any numbers in continued proportion, and from the second and the last there be subtracted [amounts] equal to the first: then, as the excess of the second is to the first, so will the excess of the last be to all those preceding it.

Let there be any numbers in continued proportion A, B, C, D, E, F; and from B C (the second) and E F (the last) let there be subtracted C G and F H, equal to the first, A. I say that as B G is to A, so is E H to A, B, C, and D together. Let F I be subtracted equal to B C, and F K equal to D. Since, then, F I is equal to B C, and the subtracted F H equal to the subtracted C G, the remainder I H will also be equal to the remainder B G. And since as A is to B C, so B C is to D, and D to E F; and, by conversion, as E F is to D, so D is to B C, and B C to A; and since K F is equal to D, and I F to B C, and H F to A: then also, as E F is to K F, so is K F to I F, and I F to H F. Therefore, dividing, as E K is to K F, so is K I to I F, and I H to H F; and

consequently, so also will all E K, K I, I H together be to all K F, I F, H F together [Margin: a. 12. septi. — Elements VII.12]—that is, the whole E H to D, B C, A together (to which K F, I F, H F were taken equal)—as I H is to H F, that is, as B G is to A; for B G and A are equal to I H and H F. Wherefore, if there are any numbers in continued proportion, and so on. Which was to be demonstrated.

A
 B G C
 D
 E K I H F

A .
 B . . G . C
 D
 E K I . . H . F

SCHOLIUM.

From this theorem we shall come to know the sum of any number of continually proportional numbers, provided the first, the second, and the last be known. For since, as the excess of the second is to the first, so is the excess of the last to all those preceding it: if the first be taken from the second and from the last, and it be arranged that, as the remainder of the second is to the first, so the remainder of the last is to another number—this other number will be the sum of all the proportional numbers that precede the last. If, then, the last be added, the whole sum will be had. And that fourth proportional is found if the first be multiplied into the excess of the last, and the product be divided by the excess of the second: as is clear from the scholium of proposition 19 of this book; since the three given numbers, to which the fourth proportional is to be found, are the excess of the second, the first, and the excess of the last. As in the example set alongside: if the first number—namely the unit—be subtracted from 3, the second, and from 2187, the last, the remaining excesses will be 2 and 2186. Since, then, as 2 is to 1, so must 2186 be to the fourth: therefore, since the first number 1 is multiplied by the third, 2186, the number 2186 is produced; which, when divided so as to give the sum of all except the last—the second number 1 being multiplied into the first, 2—yields the number 1093. That is, the sum of all, the last, 2187, excluded; and if this be added to the found sum 1003 [recte: 1093], the sum of all, 3280, is produced.

1. 3. 9. 27. 81. 243. 729. 2187.

THEOR. 34. PROPOS. 36.

[Margin: xxxix.]

If from a unit any number of numbers are set out successively in double proportion, until the whole composite becomes prime; and this whole, multiplied into the last, makes some number: the product will be perfect.

Let there be, from a unit, any numbers A, B, C, D, doubles, such that E, composed of them, is prime; and let E, multiplying D, the last, make F. I say that F is a perfect number. For as many as are the numbers A, B, C, D, let just as many doubles be taken from E—namely E, G, H, I. Since, then, A, B, C, D have the same ratio as E, G, H, I, there will be, *ex aequali*, as A is to D, so E to I [Margin: a. 19. sept. — Elements VII.19]; and for that reason the number produced from A, the first, into I—the fourth—is equal to that produced from D, the second, into E—the third. But F is produced from D into E. Therefore the same F will be produced from A into I [Margin: b. 7. pron. — Axiom 7]; and hence I measures F by A, the binary; and on that account F will be the double of I. Therefore E, G, H, I, F are successively doubles. Let there be subtracted from G (the second) and from F (the last) the numbers K, L, equal to the first, E, and let the remaining excesses be M, N. Then, as M is to E, so is N to E, G, H, I together [Margin: c. 35. noni — Elements IX.35]. But M is equal to E (for, since G is the double of E, and K, taken away, is equal to E, the remainder M will also be equal to E). Therefore N too is equal to E, G, H, I together. Adding, then, equals—namely the number L (which is equal to E, taken away) and the number composed of the unit and the numbers A, B, C, D (which composite is, by construction, equal to E)—the composite of L and N, namely F itself, will be equal to the unit and the numbers A, B, C, D, E, G, H, I together. Wherefore, since the unit and all the numbers A, B, C, D, E, G, H, I measure F (for, since F is produced from E into D, D measures F [Margin: d. 7. pro.]; and so the unit and the numbers A, B, C [Margin: e. 11. pron. — Axiom 11] which measure D measure the same F [Margin: f. 11. pron. — Axiom 11]; again, since I measures F, as has been shown, the numbers E, G, H [Margin: g. 11. pron. — Axiom 11], which measure I on account of the double proportion [Margin: h. 11. noni — Elements IX.11], also measure the same F), and no other number measures F, as we shall presently show—the unit and the numbers A, B, C, D, E, G, H, I will be all the parts that F can have. And since F has been shown equal to them, F will, by definition, be perfect.

Vnitas. A, 2. B, 4. C, 8. D, 16.
E, 31. G – 62. H, 124. I, 248. F – 496.
K, 31. M, 31. L, 31. N, 465.
O – P –

That no other number, besides A, B, C, D, E, G, H, I, measures F, we shall demonstrate thus. Let, if it be possible, another number O, besides those, measure

F by P [Margin: i. 9. pron. — Axiom 9]; and so F is produced from O into P. But the same F is produced from E, the first, into D—the fourth—and from P, the second, into O—the third; and for that reason, as E is to P, so is O to D [Margin: k. 19. septi — Elements VII.19]. Now, since A, B, C, D are proportional from the unit, and A, next to the unit, is prime, no other number besides A, B, C measures the last, D [Margin: l. 13. oct. — Elements VIII.13]; and O is assumed not the same as any one of A, B, C; therefore O will not measure D. But as O was to D, so was E to P; therefore neither will E measure P. Since, then, E is prime, E and P will be prime to one another [Margin: m. 31. septi — Elements VII.31], and therefore least in their proportion [Margin: n. 23. septi — Elements VII.23]. And consequently E measures O just as P measures D [Margin: o. 21. sexti — Elements VI.21]. But no other number besides A, B, C measures D [Margin: p. 23. octau — Elements VIII.23]. Therefore P will be the same as some one of A, B, C. Let it, then, be the same as B; and as many as are B, C, D, let just so many doubles be taken from E: E, G, H. There will then be, *ex aequali*, as B is to D, so E to H [Margin: q. 18. septi — Elements VII.18]; and consequently the same number will be produced from B, the first, into H—the fourth—as from D, the second, into E—the third. But what is produced from D into E was equal to what is produced from P into O. Therefore the same will be produced from P into O as from B into H, and so, as P is to B, so is H to O [Margin: r. 29. septi — Elements VII.29]. But P was the same as B; therefore H too is the same as O. That is absurd, for O is assumed different from all of A, B, C, D, E, G, H, I. No other number O, therefore, measures F; but A, B, C, D, E, G, H, I alone measure it. For which reason, if from a unit any number of numbers be set out successively in double proportion, and so on. Which was to be demonstrated.

SCHOLIVM.

From this theorem is drawn the method of finding all perfect numbers, and their aliquot parts, which, taken together, are—according to the definition of a perfect number—equal to the number itself. For if any number of numbers, doubled from a unit, be gathered into one sum until the composite is a prime number, the number produced from that prime into the last of the doubles will be perfect. And if, from that prime which is composed of those doubles, there be taken just as many continued doubles (the prime itself also being reckoned) as there are of those numbers doubled from the unit, the unit excluded—then these numbers taken, and those doubled from the unit, together with the unit itself, will be all the aliquot parts that the perfect number found can have. All of which are evident from the demonstration of the theorem, and easily from the examples set below—

can be grasped from the examples. For since the number 3, composed of 1 and 2, is prime, the number 6 — produced from 3 into 2, the last of the doubles — will consequently be perfect, and its aliquot parts are 1, 2, 3. Again, since the number composed of these, 1, 2, 4, namely 7, is prime, therefore 28, produced from 7 into 4, is perfect, having these aliquot parts: 1, 2, 4, 7, 14. But since the number composed of these, 1, 2, 4, 8 — that is, 15 — is not prime, 120, produced from 15 into 8, will not be perfect.

Finally, since the number composed of these, 1, 2, 4, 8, 16, namely 31, is prime, 496, produced from 31 into 16, will be a perfect number, whose aliquot parts are 1, 2, 4, 8, 16, 31, 62, 124, 248. In the same way we shall find the remaining perfect numbers as well.

It is worth demonstrating here certain properties of geometrical proportionality, on which rests that remarkable property we set out in Book 5, in the seventh place, when we were treating of geometrical proportionality; and we begin from here.

I.

When any number is divided by any two numbers, these two numbers are proportional, in reverse order, to the quotients.

For let the number A, divided by B and C, yield the quotients D and E. I say that as B is to C, so E is to D. For since, when A is divided by B, the quotient D results, A will be produced from B into D — that is, $A = B \times D$ — as we stated at Definition 15 of Book 7. By the same reasoning, the same A will be produced from C into E. Since, therefore, the same number A is produced from B (the first) into D (the fourth), and from C (the second) into E (the third), it follows [Margin: a — VII.19] that as B (the first) is to C (the second), so E (the third) is to D (the fourth). Which was to be proved.

A, 48.
B, 8. C, 3.
D, 6. E, 16.

II.

When any number is divided by any number of numbers, each pair of dividing numbers is proportional, in reverse order, to the corresponding pair of quotients.

For let the number A be divided by B, C, D, E, and let the quotients be F, G, H, I. I say that as B is to C, so G is to F; and as C is to D, so H is to G; and as D is to E, so I

is to H. This is clear from the first theorem, just demonstrated. For since the two divisors B, C of A yield F, G, it follows that as B is to C, so G is to F. Likewise, since the two divisors C, D of A yield G, H, it follows that as C is to D, so H is to G. Likewise, since the two divisors D, E of A yield H, I, it follows that as D is to E, so I is to H — and so on in turn, if there are more. Which was to be proved.

A, 48.

B, 3. C, 4. D, 8. E, 6.

F, 16. G, 12. H, 6. I, 8.

III.

When any number is divided by any number of numbers in continued proportion, the quotients, in reverse order, are in continued proportion in the same ratio.

For let the number A be divided by B, C, D, E, which are in continued proportion, and let the quotients be F, G, H, I. I say that I, H, G, F are in continued proportion in the same ratio as B is to C. For, by the second theorem, as D is to E, so I is to H; and as C is to D — that is, as D is to E — so H is to G; and as B is to C — that is, as C is to D, and as D is to E — so G is to F. Therefore I, H, G, F are in continued proportion in the ratio of D to E, or of B to C. Which was to be proved.

A, 15.

B, 1. C, 2. D, 4. E, 8.

F, 15. G, $7\frac{1}{2}$. H, $3\frac{3}{4}$ [?] I, $1\frac{1}{8}$.

IV.

If there are any numbers whatever, and just as many others in the same ratios, then as the sum of the first is to any one of them, so the sum of the second is to the one that corresponds to it among the latter.

Let there be any numbers A, B, C, whose sum is D; and just as many others E, F, G, whose sum is H; and let A be to B as E is to F, and B be to C as F is to G. I say that as D is to A, B, C severally, so is H to E, F, G severally. For since A is to B as E is to F, then by composition [componendo] A, B together will be to B as E, F together are to F; and B is to C as F is to G. Therefore, by equality [ex aequo], A, B together will be to C as E, F together are to G; and by composition, A, B, C together — that is, D — is to C as E, F, G together — that is, H — is to G.

Since, therefore, D is to C as H is to G, and, by conversion [convertendo], C is to B as G is to F, it follows by equality that D is to B as H is to F. Finally, since D is to B as H is to F, and, by conversion, B is to A as F is to E, it follows by equality that D is

to A as H is to E. Which was to be proved. And the same reasoning holds for more terms.

A, 3. B, 6. C, 20.

D, 29.

E, 6. F, 12. G, 40.

H, 58.

V.

If there are any numbers whatever, and just as many others in the same ratios, then the sum of the first, divided by them severally, will yield exactly the same quotients as the sum of the second divided by them.

For, as was shown in the fourth theorem, the ratio of the sum of the first terms to the first term is the same as the ratio of the sum of the second terms to the first; and therefore both ratios will have the same denominator. Now, since the denominator of a ratio is generated by dividing the antecedent term by the consequent, the very same quotient will be produced when each sum is divided separately by the first numbers, each by its own. And the same reasoning holds if the division is made by the second, third, fourth terms, and so on. So the proposition is established.

VI.

If the sum of any numbers in continued proportion is divided by them severally; and the sum of the quotients by those same quotients; and the sum of these second quotients by those same second quotients; and so on to infinity: the same first quotients will always be produced alternately, in reverse order.

Let there be any numbers A, B, C, D in continued proportion, whose sum E, divided by them, yields the quotients F, G, H, I; and let the sum K of these, divided by them, yield the quotients L, M, N, O. I say that these quotients and those are the same alternately, in reverse order — that is, that F and O are the same; likewise G and N; H and M; I and L; and so on.

A, 1. B, 2. C, 4. D, 8. E, 15.

F, 15. G, $7\frac{1}{2}$. H, $3\frac{3}{4}$. I, $1\frac{1}{8}$. K, $28\frac{1}{8}$.

L, $1\frac{1}{8}$. M, $3\frac{3}{4}$. N, $7\frac{1}{2}$. O, 15.

For, by the third theorem, the quotients F, G, H, I have, in reverse order, the same continued proportion as the numbers A, B, C, D; and the quotients L, M, N, O have, in reverse order, the same proportion as the quotients F, G, H, I — that is, the

same, in the same order, as the numbers A, B, C, D. Therefore, by the fourth theorem, E is to A as K is to I. Since the denominator of a ratio is produced by dividing the antecedent term by the consequent, the same quotient will result from dividing E by A as from dividing K by I. Since, then, these quotients are F and O, F and O will be equal. By the same reasoning G and N will be equal; H and M; I and L; and so on. Which was to be proved.

VII.

If the sum of any numbers in continued proportion is divided by them severally, the sum of all the quotients equals the number generated by multiplying the first into the last, or by the mutual multiplication of any two means equally distant from the extremes, or finally (if the number of quotients is odd) by multiplying the middle quotient into itself.

First let there be any numbers, even in count, in continued proportion — A, B, C, D, E, F — whose sum G, divided by them severally, yields the quotients H, I, K, L, M, N, whose sum is O. I say that the number O equals the number produced from H into N, or from I into M, or from K into L. For, by the fourth theorem, the quotients H, I, K, L, M, N are in continued proportion

A, 1. B, 2. C, 4. D, 8. E, 16. F, 32. G, 63.
H, 63. I, 31½. K, 15¾. L, 7¾. M, $3^{15}/_{16}$. N, $1^{31}/_{32}$. O, 124½ [?].

[Margin: a — VII.19] in reverse order in the ratio of A to B, so that N is to M as I is to H. Therefore the same number is generated from N into H as from M into I; that is, the same from H into N as from I into M; and by the same reasoning the same from I into M as from K into L. And since, by the sixth theorem, the sum O, divided by H, I, K, L, M, N, produces the same quotients in reverse order — that is, the sum O divided by H yields the quotient N — the sum O will be produced from H into N, by the definition; and accordingly also from I into M, and from K into L.

Next let there be any numbers, odd in count, in continued proportion — A, B, C, D, E — whose sum F, divided by them severally, yields the quotients G, H, I, K, L, whose sum is M. I say that M equals the number generated from G into

A, 1. B, 2. C, 4. D, 8. E, 16. F, 31.
G, 31. H, 15½. I, 7¾. K, 3¾. L, $1^{15}/_{16}$. M, $60^{1}/_{16}$.

L, and from H into K, and from I into itself. For that it is equal to the number made from G into L, and from H into K, we shall demonstrate as before. [Margin: b — VII.20] Then, since the three numbers H, I, K are in continued proportion, the

number generated from H into K — that is, the sum M — will be equal to the number generated by multiplying I into itself. Which was to be proved.

From this it follows that, when the number of terms is odd, the sum of the quotients is a square number whose side, or root, is the middle term.

Accordingly, if any number of terms in continued proportion in a given ratio are to be found whose sum equals the number generated from the first into the last, or from any two equally distant from the extremes, one must take, in the given ratio, as many numbers in continued proportion as are sought. For if their sum, divided by them severally,

is divided, the quotients will be the numbers sought, as is clear from this seventh theorem. But if any number of terms, odd in count, is desired whose sum is a square number whose side or root is the middle term, one must take in the given ratio the same number of terms in continued proportion, and their sum must be divided by them severally. For the quotients will be the numbers sought, as is clear from this same seventh theorem. And it is truly remarkable that one can find any number of terms in continued proportion in a given ratio — even a thousand or more — the sum of all of which equals the product of the first into the last, and the product of any two equally distant from the extremes multiplied together, and finally, if the number of terms is odd, the product of the middle term into itself.

Likewise, if one wishes for two numbers in a given ratio whose sum equals the number produced by multiplying one into the other, let him take any two numbers in the given ratio and divide their sum by each. The quotients will yield the numbers sought, as has been shown — namely, because their sum equals the number produced from the first into the last, that is, into the second. For example: let two numbers be found in sesquiquintan ratio [proportio sesquiquinta, i.e. $6 : 5$] whose sum equals the number produced by multiplying one into the other. Take any two numbers in the given sesquiquintan ratio, namely 6 and 5, and divide their sum, 11, by each. For the quotients $1\frac{5}{6}$ and $2\frac{1}{5}$ are the numbers sought. For they have the given sesquiquintan ratio, and both their sum and the number produced by multiplying them equal $4\frac{1}{30}$.

OF FRACTIONS, OR FRACTIONAL NUMBERS

DEMONSTRATIONS.

I.

Two fractions [minutiae] having the same denominator, one of which has unity for its numerator, have the same ratio as their numerators.

Let there be two fractions AB, CB having the same denominator, and let the numerator C be unity. I say that the fraction AB is to the fraction CB as the numerator A is to the numerator C. For as often as the unit C is contained in A, so often is the fraction CB included in AB; because the fraction AB is divided into as many fractions equal to CB as there are units in A, so that each of those fractions has C for its numerator and B for its denominator. [Margin: a — Def. 29]

Therefore the unit C is the same part of the number A as the fraction CB is of the fraction AB; and accordingly, as the unit C is to A, so the fraction CB is to the fraction AB. And, by conversion, as A is to C — numerator to numerator — so is the fraction AB to the fraction CB. Which was to be proved.

A, 6. C, 1.

B, 11. B, 11.

(that is, $AB = 6/11$, $CB = 1/11$)

Now, since fractions are portions, or small parts, either of unity or of some other number — for I cannot approve the opinion of those who hold that they are to be taken only with respect to unity, since they wrongly suppose that their demonstrations cannot all be carried out in whole numbers, but only in unity; whereas we, in this treatise, shall accommodate all the demonstrations to whole numbers as well — we shall endeavor to explain all the demonstrations of fractions in whole numbers, so that the diligent reader may learn even by examples that the demonstrations we bring forward are true.

Let there be given, then, the fractions $\frac{6}{11}$ and $\frac{1}{11}$, portions, for example, of the whole number 44. Since its $\frac{1}{11}$ is 4 and its $\frac{6}{11}$ is 24, it is clear that 4 is to 24 as the numerator 1 is to the numerator 6; or, put otherwise, 24 is to 4 as 6 is to 1. This proposition we shall demonstrate in general, at Proposition 4, for any two fractions of the same denomination, even if neither has unity for its numerator.

II.

The numerator of any fraction has the same ratio to the denominator as the fraction has to the whole of which it is a fraction.

Let AB be any fraction. I say that the numerator A is to the denominator B as the fraction AB is to its whole. Take the fraction CB, whose numerator C is unity and whose denominator is the same B; likewise take another fraction whose numerator D is equal to that same denominator B, so that it equals its whole. For when the numerator equals the denominator, the fraction is equivalent to its whole: since it contains as many parts of the whole as those into which the whole itself is divided, and accordingly contains the whole. [Margin: b — Prop. 1 of this treatise] Since, therefore, A is to C as the fraction AB is to the fraction CB, and C is to D as the fraction CB is to the fraction DB, it follows by equality that A is to D — that is, the numerator A is to the denominator B (since D equals B) — as the fraction AB is to the fraction DB, that is, to the whole. Which was to be proved.

A, 3. C, 1. D, 5.
B, 5. B, 5. B, 5.

(that is, $AB = 3/5$, $CB = 1/5$, $DB = 5/5$)

Otherwise: Let it first be granted that in the given fraction AB the numerator A is unity, so that the fraction is an aliquot part of the whole C — whether C be unity or a number — an aliquot part, I say, denominated by B; because as many fractions equal to AB make up the whole C as there are units in the denominator B. Since, therefore, the unit A is a part of the number B, being derived from that same B,

A, 1. C, 1.
B, 5. C, 30. [?]

(that is, $AB = 1/5$; the second array reads $1/30$, but both labels appear as C — uncertain)

Note on the reference letters in the margins: each lowercase letter (a, b, c...) keys a superscript marker in the demonstration to a cited authority. In the citations, "**huius**" = a proposition of this treatise on fractions; "**sept.**" / "**septi.**" = a proposition of Euclid's *Elements*, Book VII; "**def.**" = a definition. These are rendered below as [Margin: <letter> · <citation>].

The lettered number- and fraction-schematics are set inline as monospace panels; a $\times$ between two fractions marks the cross-multiplication of numerators into denominators.

[Continuation of the demonstration of Proposition II, from the preceding page — the numerator being unity.]

as we wrote at definition 2 of Book VII; the unit A will be the same part of the number B that the fraction AB is of the whole C. [Margin: c · 20. def.] Therefore the numerator A will be to the denominator B as the fraction AB is to the whole C — which was to be proved.

Next, let the numerator A **not** be unity. Take the fraction DB, whose numerator is D — unity — and whose denominator is the same B as that of the fraction AB. [Margin: d · 1. huius] Since, then, A is to D as numerator to numerator, so is the fraction AB to the fraction DB; and since D is to B as the fraction DB is to the whole C (as we proved just above), it follows *ex aequo* that A is to B, numerator to denominator, as the fraction AB is to the whole C. Which was to be proved.

A, $\frac{3}{5}$ D, $\frac{1}{5}$ C, 1
C, 30

And so, if the given fraction $\frac{3}{5}$ be a fraction of the whole number 30, its $\frac{1}{5}$ will be the number 6, and accordingly its $\frac{3}{5}$ the number 18 — where you see that 18 is to 30 as 3 is to 5, numerator to denominator.

III.

Every fraction is a part of its numerator, named by its denominator.

[Margin: c · 2. huius] Let AB be any fraction. I say that it is a part of the numerator A, named by the denominator B. For since A is to B, numerator to denominator, as the fraction AB is to its own whole C, then by alternation A is to the fraction AB as B is to the whole; and by inversion, the fraction AB is to A as the whole is to B (that is, the whole taken as many times as there are units in the denominator B), named by that same denominator B. (For since the unit measures the denominator, and likewise measures the whole itself — the whole being taken as many times as there are units in the denominator; and since the unit is a part of the denominator named by the denominator, as we wrote at definition 2 of Book VII — the whole too will be the same part of the whole-taken-repeatedly as there are units in the denominator.) Therefore the fraction AB likewise will be that same part of the numerator A (that is, of the whole taken as many times as there are units in the numerator A), named by the denominator B. Which was to be proved.

Let the fraction $\frac{3}{5}$ be supposed to be a fraction of this whole, 30; then its $\frac{3}{5}$ is worth 90, and its denominator is worth 150. (Just as, when the same fraction $\frac{3}{5}$

is taken with respect to unity, the numerator contains three units and the denominator five.) It is then plainly established that 18 is the fifth part of the numerator — that is, of three units, each of which stands for the whole number 30, and which three units make 90 — the part, I say, named by the denominator 5; just as 30, the given whole number, is the fifth part of the denominator — that is, of five units, each of which stands for the whole number 30, and which five units make up 150 — the part, I say, named by the denominator 5.

IV.

Given fractions that have the same denominator, neither of which has unity for its numerator, are to one another in the same ratio as their numerators.

[Margin: f · 2. huius] What was shown in the first proposition of two fractions, one of which has unity for its numerator, is here demonstrated of any fractions whatever. So let there be two fractions AB, CB having the same denominator B. I say that the fraction AB is to the fraction CB as A is to C, numerator to numerator. [Margin: f] For since A is to B as the fraction AB is to its own whole, and B is to C as the whole is to the fraction CB [Margin: g · 2. huius] (for [6] since C is to B as the fraction CB is to the whole, then by inversion B is to C as the whole is to the fraction CB), it follows *ex aequo* that A, the numerator, is to C, the numerator, as the fraction AB is to the fraction CB. Which was to be proved.

A, $\frac{6}{7}$ C, $\frac{3}{7}$

Let the given fractions $\frac{6}{7}$ and $\frac{3}{7}$ be fractions of this whole, 28; then its $\frac{6}{7}$ is 24 and its $\frac{3}{7}$ is 12 — where it is clear that 24 is to 12 as the numerator 6 is to the numerator 3.

V.

If the numerator of the first of two fractions is multiplied into the denominator of the second, and the numerator of the second into the denominator of the first, then the first fraction will be to the second as the first product is to the second.

Let there be two fractions AB, CD; and from A into D let F be made, and from C into B let G be made. I say that the fraction AB is to the fraction CD as F is to G. [Margin: h · 18. septi.] Let H be made from B into D. Since, then, A and B, multiplying D, make F and H, it follows that A is to B as F is to H. But as A is to B, [Margin: i · 2. huius] so is the fraction AB to the whole. Therefore also the fraction AB is to the whole as F is to H. Again, since C and D, multiplying B, make G and H,

[Margin: k · 18. sept.] it follows that C is to D as G is to H; and by inversion, D is to C as H is to G. But as D is to C, so is the whole to the fraction CD; [Margin: l · 2. huius] for since C is to D as the fraction CD is to the whole, then by inversion D is to C as the whole is to the fraction CD. Therefore also H is to G as the whole is to the fraction CD. Hence *ex aequo* it follows that F is to G as the fraction AB is to the fraction CD. Which was to be proved.

F, 10 G, 12
A, $\frac{2}{3} \times C$, $\frac{4}{5}$
H, 15

[p. 383 — running header "LIBER IX."; the demonstration of Proposition V continues, with the correspondence displayed:]

F, AB
H, Integrum (the whole)
G, CD

If two fractions $\frac{2}{3}$ and $\frac{4}{5}$ are fractions of the number 30, then two-thirds of it are 20, and four-fifths of the same are 24. It is clear that 20 is to 24 as 10 is to 12 — the two numbers begotten from the numerators into the denominators, in swapped order.

And so, if the product F be equal to the product G, then the fraction AB will also be equal to the fraction CD; if less, less; if greater, greater — on account of the same ratio, F to G and fraction to fraction. And this is the demonstration of the rule we gave in the *Arithmetic* for discerning which of two fractions is the greater.

VI.

The whole has the same ratio to the sum of two fractions as the number produced by the mutual multiplication of the denominators has to the sum of the two products — of which one is begotten from the numerator of the first fraction into the denominator of the second, the other from the numerator of the second into the denominator of the first.

Let there be two fractions AB, CD. From B into D let H be made; from A into D let F be made, and from C into B let G be made. I say that the whole is to the sum of the fractions AB, CD as H is to the sum of the numbers F, G. [Margin: m · 5. huius] For since the fraction AB is to the fraction CD as F is to G, then by composition the sum of the fractions AB, CD is to the fraction CD as the sum of the numbers F, G is to G. But as the fraction CD is to the whole, so is G to H (for [Margin: n · 2. huius] as the fraction CD is to the whole, so is C to D; [Margin: o · 18. septi.] and as C is to

D, so is G to H, because G and H were made by G and D multiplying B). Therefore *ex aequo* the sum of the fractions AB, CD is to the whole as the sum of the numbers F, G is to H; and by inversion, the whole is to the sum of the fractions AB, CD as H is to the sum of the numbers F, G. Which was to be proved.

F, 10 G, 12
A, $\frac{2}{3} \times C$, $\frac{4}{5}$
H, 15

AB, CD, F, G
CD, G
Integrum, H

Again, let there be two fractions $\frac{2}{3}$ and $\frac{4}{5}$, fractions of the number 30; two-thirds of it are 20, and four-fifths of the same 24, so that the sum of the fractions is 44. Here you see that the whole 30 is to this sum 44 as 15 (the product of the denominators) is to 22 [? — small glyph at the resolution floor; confirmed by the arithmetic and by the stated "sum of the numbers 10, 12"], the sum of the numbers 10 and 12, produced from the numerators into the denominators in swapped order.

VII.

If two fractions have the same numerator, the first fraction will be to the second as the denominator of the second is to the denominator of the first.

Let two fractions AB, AC have the same numerator A. I say that the fraction AB is to the fraction AC as the denominator C is to the denominator B. Let D be made from A into C, and E from A into B. Since, then, A multiplying C and B makes D and E, [Margin: $p \cdot 17$. sept.] it follows that D is to E as C is to B. But as D is to E, [Margin: $q \cdot 5$. huius] so is the fraction AB to the fraction AC. Therefore also the fraction AB is to the fraction AC as C is to B. Which was to be proved.

D, 105 E, 35
A, $\frac{5}{7} \times A$, $\frac{5}{21}$
B, 7 C, 21

Let the two fractions $\frac{5}{7}$ and $\frac{5}{21}$ be fractions of the whole number 42; then its $\frac{5}{7}$ are 30, and its $\frac{5}{21}$ are 10. And it is manifest that 30 is to 10 as the latter denominator 21 is to the former, 7.

VIII.

Fractions whose numerators bear the same ratio to their denominators are equal; and the numerators of equal fractions bear the same ratio to

their denominators. But the fraction whose numerator bears the greater ratio to its denominator is the greater; and the greater fraction is the one whose numerator bears the greater ratio to its denominator.

Let there be two fractions AB, CD, and let the ratio of A to B (numerator to denominator) be the same as that of C to D. I say that these fractions are equal. [Margin: $r \cdot 2$. huius] For since A is to B as the fraction AB is to the whole, and C is to D as the fraction CD is to the same whole, and A is to B (by hypothesis) as C is to D, then also the fraction AB is to the whole as the fraction CD is to the same whole. Therefore the fractions AB, CD are equal. Which was to be proved.

A, $\frac{3}{4}$ C, $\frac{9}{12}$

But now let the fractions AB, CD be equal. I say that A is to B as C is to D. For since the fractions are equal, the fraction AB will be to the whole as the fraction CD is to the same whole. [Margin: $s \cdot 2$. huius] But the fraction AB is to the whole as A is to B, and the fraction CD is to the whole as C is to D. Therefore also A is to B as C is to D. Which was to be proved.

[p. 384 — running header "EVCLID. GEOM."; Proposition VIII continues:]

Next, let the ratio of A to B be greater than that of C to D. I say that the fraction AB is greater than CD. [Margin: $a \cdot 2$. huius] For since A is to B as the fraction AB is to the whole, and C is to D as the fraction CD is to the same whole, and the ratio of A to B is supposed greater than that of C to D, then the ratio of the fraction AC [recte: AB] to the whole will also be greater than that of the fraction CD to the same whole. Therefore the fraction AB is greater than the fraction CD. Which was to be proved.

A, $\frac{3}{4}$ C, $\frac{2}{3}$

But now let the fraction AB be greater than the fraction CD. I say that the ratio of A to B is greater than that of C to D. [Margin: $b \cdot 2$. huius] For the ratio of the fraction AB (the greater) to the whole will be greater than the ratio of the fraction CD (the lesser) to the same whole. Since, then, the fraction AB is to the whole as A is to B, and the fraction CD is to the whole as C is to D, the ratio of A to B will also be greater than that of C to D. Which was to be proved.

Let 24 be the whole number of the fractions $\frac{3}{4}$ and $\frac{12}{16}$ [? — the second, small stacked glyph sits at the resolution floor; it is a fraction equal to $\frac{3}{4}$ (both give 18 of 24) and could also read $\frac{9}{12}$]; both $\frac{3}{4}$ and $\frac{12}{16}$ of it are 18, and so the fractions $\frac{3}{4}$ and $\frac{12}{16}$ are equal. But $\frac{2}{3}$ of the same number 24 are 16 — where

it is manifest that the number 18 is greater than the number 16, and therefore that the fraction $\frac{3}{4}$ is greater than the fraction $\frac{2}{3}$.

IX.

Fractions whose numerators bear the same ratio [to each other] as their denominators are equal; and the numerators of equal fractions bear the same ratio as their denominators. But that fraction whose numerator bears the greater ratio is the greater; and the numerator of the greater fraction bears a greater ratio than does its denominator.

Let there be two fractions AB, CD, and let the ratio of A to C be the same as that of B to D. I say that the fractions themselves are equal. For by alternation A will be to B as C is to D; [Margin: $c \cdot 8$. huius] and accordingly the fractions will be equal. Which was to be proved.

A, $\frac{6}{9}$ C, $\frac{2}{3}$

But now let the fractions AB, CD be equal. I say that A is to C as B is to D. [Margin: $d \cdot 8$. huius] For A will be to B as C is to D. Therefore by alternation A is to C as B is to D. Which was to be proved.

Next, let the ratio of A to C be greater than that of B to D. I say that the fraction AB is greater than the fraction CD. For by alternation the ratio of A to B will also be greater than that of C to D, [Margin: $e \cdot 8$. huius (printed "c")] and on that account the fraction AB will be greater than CD. Which was to be proved.

A, $\frac{6}{9}$ C, $\frac{3}{5}$

But now let the fraction AB be greater than CD. I say that the ratio of A to C is greater than that of B to D. [Margin: $f \cdot 8$. huius] For the ratio of A to B will be greater than that of C to D, and therefore by alternation the ratio of A to C will be greater than that of B to D. Which was to be proved.

Let the two fractions $\frac{6}{9}$ [? — the numerator glyph reads 5 or 6 at the floor; the adjacent printed "60" pins it at $\frac{6}{9}$] and $\frac{2}{3}$ be fractions of the whole number 90. Here you see that the fraction $\frac{6}{9}$, that is 60, is equal to the fraction $\frac{2}{3}$, that is to the number 60; but that same fraction $\frac{6}{9}$, that is 60, is greater than the fraction $\frac{3}{5}$, that is the number 54.

X.

To reduce two fractions of different denominations to two other fractions of the same denomination equal to them.

Let two fractions AB, CD have unlike denominators B, D. Let E be made from A into D, F from C into B, and G from B into D. I say that the fractions EG, FG — whose numerators are E, F and whose common denominator is G — are equal to the fractions AB, CD. [Margin: g · 18. sept.] For since A and B, multiplying D, make E and G, it follows that A is to B as E is to G. [Margin: h · 8. huius] Hence the fractions AB, EG will be equal. In the same way, since C and D, multiplying B, make F and G, [Margin: i · 18. septi.] it follows that C is to D as F is to G. [Margin: k · 9. huius] Therefore the fractions CD, FG will be equal. Which was to be proved.

E, 10 F, 9
A, $\frac{2}{3} \times C$, $\frac{3}{5}$
G, 15

XI.

To reduce any whole number to a fraction of a given denominator.

Let first A be the whole number 1, to be reduced to a fraction whose denominator is C. Take a numerator B equal to the denominator C. I say that the fraction BC is equal to the unit A. [Margin: l · 2. huius] For since B is to C as the fraction BC is to the whole A, and B is equal to C, then the fraction BC will also be equal to the whole A — that is, to unity. Which was to be proved.

A, 1 B, $\frac{6}{6}$

Next, let A be a whole number to be brought back to a fraction whose denominator is C. From A into C let B, the numerator, be made. I say that the fraction BC is equal to the whole A. For let the unit D be supposed under the whole A, so that the fraction AD is made equal to as many units as there are units in A. Since, then, B is made from A into C, it follows from the definition of multiplication that B is to C as A is to D, the unit. [Margin: m · 8. huius] Since, then, the fractions AD, BC have their numerators A, B in the same ratio to their denominators D, C, they will be equal to one another. And since the fraction AD is equal to the whole A (on account of its denominator, which is unity), the fraction BC too will be equal to the same whole A. Which was to be proved.

A, 7 B [recte for printed "C"], 42
D, 1 C, 6

XII.

To double and to halve a given fraction.

Let the fraction A/B first be the one to be doubled. Either double the numerator A to make a numerator C, keeping the same denominator B; or, when it is even,

halve the denominator B to make a denominator D, keeping the same numerator A. I say that each of the two fractions, C/B and A/D , is double the fraction A/B . For since AB and CB have the same denominator, [Margin: a — 4. huius] C will be to A, numerator to numerator, as CB is to AB, fraction to fraction. But C is double A, by construction. Therefore the fraction CB is also double the fraction AB. Which was to be proved.

Again, since the fractions AB and AD have the same numerator, [Margin: b — 7. huius] B will be to D, denominator to denominator, as AD is to AB, fraction to fraction. But B is double D, by construction. Therefore the fraction AD too is double the fraction AB. Which was to be proved.

$A/B = 3/8 \rightarrow C/B = 6/8$ (double the numerator) or $A/D = 3/4$ (halve the denominator)

Next, let the fraction A/B be the one to be halved. Either double the denominator B to make a denominator C, keeping the same numerator A; or, when it is even, halve the numerator A to make a numerator D, keeping the same denominator B. I say that each of the two fractions, A/C and D/B , is half the fraction A/B . For since AB and AC have the same numerator, [Margin: c — 7. huius] B will be to C, denominator to denominator, as AC is to AB, fraction to fraction. Since, then, B is by construction half of C, the fraction AC will also be half the fraction AB. Which was to be proved.

Again, since the fractions AB and DB have the same denominator, [Margin: d — 4. huius] D will be to A, numerator to numerator, as DB is to AB, fraction to fraction. Since, then, D is half of A, by construction, the fraction DB too will be half the fraction AB. Which was to be proved.

$A/B = 6/11 \rightarrow A/C = 6/22$ (double the denominator) or $D/B = 3/11$ (halve the numerator)

In the same way a given fraction will be tripled, quadrupled, and so on, either if the numerator is tripled, quadrupled, and so on, the same denominator remaining; or (when it can be done) if a third, a fourth, and so on, of the denominator is taken, the same numerator remaining.

And likewise a third part, a fourth part, and so on, of a given fraction will be taken, either if the denominator is tripled, quadrupled, and so on, the same numerator remaining; or (when it can be done) if a third part, a fourth part, and so on, of the numerator is taken. Which is proved in the same way.

XIII.

A fraction of a fraction is equal to a simple fraction whose numerator is produced by multiplying the two numerators together, and whose denominator by multiplying the two denominators together.

For let AB be a fraction of the fraction CD with respect to the whole number E, that is, of the unit E, and let a simple fraction K express the value of this fraction. Let F be made from A into C, and G from B into D. I say that the given fraction-of-a-fraction is equal to the simple fraction FG — with respect to the whole E — whose numerator is F and denominator G. For let H in turn be made from C into B. [Margin: e — 2. huius] And since, as A is to B, so is the fraction AB to its own whole, namely to the fraction CD, whose whole is E; [Margin: f — 18. septi] and likewise, as A is to B, so is F to H (because A and B, multiplying C itself, make F and H): therefore, as the fraction AB is to the fraction CD, so also will F be to H. Again, [Margin: g — 2. huius] since, as C is to D, so is the fraction CD to its own whole E; [Margin: h — 17. septi] and likewise, as C is to D, so is H to G (because B, multiplying C and D themselves, has made H and G): therefore, as the fraction CD is to its own whole E, so also will H be to G. Since, then, as the fraction AB is to the fraction CD, so is F to H; and as the fraction CD is to the whole E, so is H to G; it will hold, *ex aequo*, that as AB — a fraction of the fraction CD — is to the whole E, so is F to G. But as AB, a fraction of the fraction CD, is to the whole E, so also is the simple fraction K to that same whole E, since K was set equal to the given fraction AB of the fraction CD (for it expresses its value with respect to the whole E). Therefore it will also hold that, as F is to G, so is the simple fraction K to the whole E. [Margin: i — 2. huius] Since, then, as F is to G, so also is the fraction FG to that same whole E of its own, the simple fractions K and FG will be equal. And accordingly, since K is equal to the given fraction-of-a-fraction, the simple fraction FG too will be equal to the given fraction AB of the fraction CD, whose whole is E. Which was to be proved.

$A/B = 2/3$ (= AB); $C/D = 3/4$ (= CD); $F = A \times C = 6$; $G = B \times D = 12$; $H = C \times B = 9$
simple $K = F/G = 6/12 = 1/2$; whole $E = 24$ (unit $E = 1$) segments listed: A B ·
C D · E || F · H · G

Let $\frac{2}{3}$ be a fraction of the fraction $\frac{3}{4}$ with respect to the integer 24. Three-fourths of this number is 18, and two-thirds of that is 12, which is $\frac{1}{2}$ of the given whole number 24. And it is manifest that if the numerators 2 and 3 are multiplied together, and likewise the denominators 3 and 4, the fraction $\frac{6}{12}$ is produced, which is equivalent to $\frac{1}{2}$ — just such a part, indeed, as the number 12 was with respect to the whole number 24.

XIII.

To reduce a fraction of a fraction, or a fraction of fractions, to a simple fraction.

Let AB first be a fraction of the fraction CD. From A into C let E be made, and from B into D let F be made. [Margin: k — 13. huius] And since the fraction EF expresses

the value of the fraction AB with respect to the fraction CD, the given fraction-of-a-fraction will have been reduced to the simple fraction EF. Which was to be proved.

$A/B = 2/3 (= AB)$; $C/D = 3/4 (= CD)$; $E = A \times C = 6$; $F = B \times D = 12$; simple EF = $6/12$

Next, let AB be a fraction of the fractions CD and EF, such that CD is a fraction of the fraction EF, and AB a fraction of the fraction CD. Let G be made from A into C, and H from B into D; then let I be made from G into E, and K from H into F; and so on in succession, the last-produced numbers I and K being multiplied into the numbers of the next fraction. I say that the fraction IK, whose numerator is I and denominator K, is equal to the given fraction-of-fractions. [Margin: a — 13. huius] For the fraction GH is equal to AB — a fraction of the fraction CD — taken with respect to the fraction EF as a kind of whole. [Margin: b — 13. huius] Likewise the fraction IK is equal to the fraction GH (that is, to AB, a fraction of the fraction CD), a fraction of EF, with respect to the whole of which EF is itself a fraction; and so on in succession, if there are more fractions. Therefore the fraction IK, constituted from the numbers produced in the last place, is equal to the given fraction-of-fractions. Which was to be proved.

$A/B = 2/3$; $C/D = 3/4$; $E/F = 1/2$; $G = A \times C = 6$; $H = B \times D = 12$ $I = G \times E = 6$; $K = H \times F = 24$; $IK = 6/24$

Let $\frac{2}{3}$ be a fraction of the fractions $\frac{3}{4}$ and $\frac{1}{2}$ with respect to the integer 24. Half of this number is 12; three-fourths of that is 9; and finally two-thirds of that is 6, which is $\frac{1}{4}$ of the whole integer 24. And it clearly stands that, if the numerators 2, 3, 1 are multiplied together, and likewise the denominators 3, 4, 2, the fraction $\frac{6}{24}$ is produced, which is equal to $\frac{1}{4}$ — just such a part, indeed, as the number 6 was with respect to the whole 24.

XV.

Given two fractions, to reduce one of them to another equal to it, in such a way that the numbers of the one measure the numbers of this newly

found fraction — namely, by the numbers produced from the numerator of the given fraction being multiplied into the denominator of the other given fraction, and from the numerator of the other given fraction into the denominator of the [first] reduced fraction.

Let there be two fractions AB and CD, of which AB is to be reduced to another equal to it, such that its numerator is measured by the numerator C through the number produced from A into D, and its denominator is measured by the denominator D through the number produced from C into B. Let F be made from C into D; and from F into A and B let G and H be made. Likewise, from A into D let K be made, and L from C into B. I say that the fraction GH is equal to the fraction AB; and that C measures G through K (produced from A into D), and D measures H through L (produced from C into B). For since F, multiplying AB, makes G and H, [Margin: c — 17. sept] as A is to B, so will G be to H; [Margin: d — 7. huius] and accordingly the fractions AB and GH will be equal. Next, since C, multiplying D, makes F, [Margin: e — 9. pro. [?]] C measures F itself through D; [Margin: f — 5. pro. [?]] and the unit likewise measures D itself through D. The same part, therefore, is C of F as the unit is of D. Since, then, the unit is a part of D denominated by D, C too will be a part of F denominated by D. By the same reasoning F will be a part of G denominated by A, because G is made from F into A. Since, then, C is a fraction of the fraction F with respect to the whole G, and the numerators are units, and the denominators are the numbers D and A by which the parts C and F are denominated, [Margin: g — 13. huius] C — a fraction of the fraction F with respect to the whole G — will constitute a simple fraction M (the fractions C, F, M being those we wrote out separately) with respect to that same whole G, whose numerator, that is, is produced from the numerators of the fractions C and F, and whose denominator from their denominators. Therefore, since the numerators produce the unit and the denominators the number K (for the numerators are units, while the denominators are the numbers D and A, by which the parts C and F are denominated, and from whose multiplication the number K was made), the fraction C of the fraction F, with respect to the whole G, will constitute a simple fraction of that same whole G whose numerator is the unit and denominator the number K, equal to the fraction M. And accordingly C, the numerator of the given fraction CD, which constitutes C — a fraction of the whole G denominated by the number K. Wherefore the number C will measure G itself through K, taken as many times, that is, as the unit is contained in the number K. By exactly the same reasoning we shall show that D measures H itself through the number L. Which was to be proved.

$A/B = 2/3$; $C/D = 3/4$; $F = C \times D = 12$; $G = F \times A = 24$; $H = F \times B = 36$ $K = A \times D = 8$; $L = C \times B = 9$; $GH = 24/36 = 2/3 (= AB)$ auxiliary simple fractions: $C = 1/4$; $F = 1/2$; $M = 1/8$

XVI.

Two fractions whose numerators, multiplied crosswise into the denominators, produce equal numbers, are equal; and the numerators of equal fractions, multiplied crosswise into the denominators, produce equal numbers. But that fraction whose numerator, multiplied into the denominator of the other, produces the greater number, is the greater; and the numerator of the greater fraction, multiplied into the denominator of the other, produces the greater number.

Let there be two fractions AB and CD; and from A into D let E be made, and from C into B let F be made; and let the numbers E and F first be equal. I say that the fractions AB and CD are equal. For since the number E, made from A (the first) into D (the fourth), is equal to the number F, made from C (the second) into B (the third), [Margin: h — 19. septi] A, the first, will be to C, the second — numerator to numerator — as B, the third, is to D, the fourth — denominator to denominator. [Margin: i — 9. huius] Therefore the fractions AB and CD are equal. Or thus: [Margin: k — 5. huius] since, as E is to F, so is the fraction AB to the fraction CD, and E is equal to F, the fraction AB will also be equal to the fraction CD. Which was to be proved.

$$A/B = 2/3 \rightarrow$$

$$E/D = 8/12; E = A \times D = 24; F = C \times B = 12$$

But now let the fractions AB and CD be equal. I say that the number E is also equal to the number F. For, on account of the equality of the fractions, [Margin: a — 9. huius] as A is to C, numerator to numerator, so will B be to D, denominator to denominator. [Margin: b — 19. septi] Wherefore the same number will be made from A (the first) into D (the fourth) as from C (the second) into B (the third); and accordingly the numbers E and F will be equal. Or thus: [Margin: c — 5. huius] since, as the fraction AB is to the fraction CD, so is E to F, and the fractions are set equal, the numbers E and F will also be equal. Which was to be proved.

Next, let E be a number greater than the number F. I say that the fraction AB too is greater than the fraction CD. For since, from A into D, the number E is made greater than F, F will be generated from a number smaller than A — into D — namely from G into D. Since, then, the same number F is made both from G (the first) into D (the fourth) and from C (the second) into B (the third), [Margin: d — 19. septi] G, the first, will be to C, the second, as B, the third, is to D, the fourth. But

the ratio of A to C is greater than that of G to C (since A is greater than G).

Therefore [Margin: e — 9. huius] the ratio of A to C will also be greater than that of B to D; and accordingly the fraction AB will be greater than the fraction CD. Or thus: [Margin: f — 5. huius] since, as E is to F, so is the fraction AB to the fraction CD, and E is greater than F, the fraction AB will also be greater than the fraction CD. Which was to be proved.

$A/B = 2/3 \times C/D = 7/12$; $E = A \times D = 24$; $F = C \times B = 21 \rightarrow E > F$, so $AB > CD$ $G = 1\frac{3}{4}$ [?] (the number such that $F = G \times D$)

Finally, let the fraction AB now be greater than the fraction CD. I say that the number E is also greater than the number F. For since the fraction AB is greater than the fraction CD, [Margin: g — 9. huius] the ratio of A to C will be greater than that of B to D. A number smaller than A, therefore, will have to C the same ratio that B has to D; let this be G. [Margin: h — 19. septi] The same number, then, will be made from G (the first) into D (the fourth) as from C (the second) into B (the third). Since, then, from A into D a greater number is made than from G into D — because A is greater than G — E, made from A into D, will also be greater than F, generated from C into B. Or thus: [Margin: i — 5. huius] since, as the fraction AB is to the fraction CD, so is E to F, and the fraction AB is greater than the fraction CD, E will also be greater than F. Which was to be proved.

And this is also the demonstration of that rule which we laid down in the Arithmetic for determining which of two given fractions is the greater. This we noted at the 5th proposition as well.

XVII.

To reduce a given fraction to its lowest terms.

Let AB be the fraction to be brought back to its lowest terms. If, then, A and B are prime to one another, the fraction AB cannot be brought back to smaller terms, but is already constituted in its lowest terms. For let it be reduced, if it can be, to smaller terms C, D, such that the fraction CD is equal to the fraction AB. [Margin: k — 8. huius] Since, then, as A is to B, so is C to D, and C, D are numbers smaller than the numbers A, B, then A and B will not be the least terms in their ratio; [Margin: l — 23. septi] yet they are the least, since they are prime to one another — which is absurd.

$A/B = 11/12$; $C/D = -$ (no smaller equal terms exist, A and B being coprime)

But if A, B are not prime to one another, [Margin: m — 2. septi] let C be their greatest common measure, which measures A through D and B through E. I say

that the fraction DE, whose numerator is D and denominator E, is equal to the given fraction AB, and is constituted in its lowest terms. For since C measures A and B through D and E, [Margin: n — 9. pro. [?]] A and B will be produced from C into D and E. [Margin: o — 17. sept] Wherefore, as A is to B, so will D be to E; [Margin: p — 8. huius] and on that account the fractions AB and DE will be equal. Next, since C, the greatest measure of the numbers A and B, measures them through D and E, then — by the corollary of proposition 35 of Book 7 — D and E are the least in the ratio of A to B. Which was to be proved.

$A/B = 36/48$; $C = 12$ (greatest common measure); $D = 3$; $E = 4$; $DE = 3/4$

XVIII.

To reduce a given fraction to another equal to it of a given denomination, when this can be done.

Let AB be a given fraction, to be brought back to another equal to it whose denominator is a given C. From A, the numerator, into the given denominator C, let D be made, which B — the denominator of the given fraction — measures through E. I say that the fraction EC, whose numerator is E and denominator the given C, is equal to the given fraction AB. For since B measures D through E, [Margin: q — 9. pro. [?]] D will be made from B into E; but the same D was made from A into C. [Margin: r — 19. septi] Therefore, as A, the first, is to B, the second, so will E, the third, be to C, the fourth; [Margin: s — 8. huius] and hence the fractions AB and EC will be equal. Which was to be proved.

$A/B = 3/4$; given denominator $C = 12$; $D = A \times C = 36$; $E = D/B = 9$; $EC = 9/12$

But if B does not measure D — produced from A into C — the given fraction AB cannot be reduced to the given denomination C. For let it be reduced, if it can be, to the fraction EC. Since, then, the fractions AB and EC are equal, [Margin: t — 8. huius] as A is to B, so will E be to C. [Margin: u — 19. septi] The same number, therefore, will be made from A (the first) into C (the fourth) as from B (the second) into E (the third) — namely the number D, made from A into C. [Margin: x — 7. pro. [?]] Therefore B will measure D through E. Which is absurd; for B was assumed not to measure D itself.

$A/B = 3/4$; given denominator $C = 10$; $D = A \times C = 30$; $E = -$ ($B = 4$ does not measure 30, so EC cannot be formed)

XIX.

When a smaller number is divided by a larger, the quotient is a fraction whose numerator is the smaller number divided, and whose denominator is the larger dividing number.

This opening completes the demonstration of Proposition XIX of the fractions treatise (whose enunciation stood at the end of the previous stretch), then runs through the propositions on adding, subtracting, multiplying, dividing, and grafting fractions. The running head remains **LIBER IX** — the *Elements* Book X has not yet begun.

Demonstration of Proposition XIX (a smaller number divided by a larger yields a fraction):

Let the smaller number A be divided by the larger number B. I say that the quotient is the fraction A/B, whose numerator is A and whose denominator is B. [Margin: a. Prop. VIII of this treatise (8. huius)] For A is to B as the divided number is to the divisor — that is, as the numerator is to the denominator — so the fraction A/B is to the whole, that is, to unity. Therefore, by the definition of division, the fraction A/B is the quotient of the division of the number A by the number B, which was the point to be proved.

$$AB = 6/11$$

It follows from this that, when a larger whole number is divided by a smaller whole number and something is left over, one must still add to the whole-number quotient already obtained a fraction whose numerator is the number left over from the division and whose denominator is the dividing number. For that remainder, which is necessarily smaller than the divisor, must still be divided by that same larger divisor. For example: dividing the number 23 by 4, the whole-number quotient is 5, and 3 remains, still to be divided by 4. [Margin: b. Prop. XIX of this treatise (19. huius)] There results, then, the fraction 3/4, so that the whole quotient is $5 \frac{3}{4}$.

XX.

To collect several fractions into a single sum.

Let there first be two fractions AB and CB to be added, of the same denomination. From the numerators A and C form the sum D, and give it the same denominator B. I say that the fraction DB is the sum collected from the addition of the fractions AB and CB. For since the fractions have the same denominator, [Margin: c. Prop.

IV (4. huius)] A is to C as the fraction AB is to the fraction CB; and by composition, A and C together are to C as the fractions AB and CB together are to the fraction CB. [Margin: d. Prop. IV (4. huius)] And as C is to D, so too is the fraction CB to the fraction DB. Therefore, *ex aequo*, A and C together are to D as the fractions AB and CB together are to the fraction DB. Since, then, A and C together are equal to D itself by construction, the fractions AB and CB together will likewise be equal to the fraction DB — which was to be proved.

$$AB = 3/10 \quad CB = 4/10 \quad DB = 7/10$$

Next, let there be two fractions AB and CD to be added, of different denominations. Multiply A, the numerator of the first, into D, the denominator of the second; and C, the numerator of the second, into B, the denominator of the first; and let the sum of these two products be E, to which is assigned the denominator F, produced by the mutual multiplication of the denominators B and D. I say that the fraction EF is the sum collected from the two given fractions AB and CD. [Margin: e. Prop. VI (6. huius)] For the whole is to the sum of the two fractions AB and CD as F, produced from the denominators, is to E, the sum of the products of the numerators multiplied crosswise into the denominators; therefore, by conversion, the sum of the fractions AB and CD is to the whole as E is to F. [Margin: f. Prop. II (2. huius)] And as E is to F, so too is the fraction EF to that same whole. Therefore the sum of the fractions AB and CD is to the whole as the fraction EF is to that same whole. Hence the sum of the fractions AB and CD is equal to the fraction EF, and so the fraction EF is the sum collected from the fractions AB and CD — which was to be proved.

$$AB = 2/3 \times CD = 3/4 \rightarrow EF = 17/12$$

Or thus. From the multiplication of the numerators into the denominators crosswise, and from the multiplication of the denominators by one another, there arise two fractions of the same denomination equal to the fractions AB and CD, as is established by the demonstration of Proposition X. So if to the sum E of the products of the numerators into the denominators one assigns F, the common denominator produced from the denominators, then the fraction EF becomes the sum of the fractions AB and CD — that is, of the two fractions of the same denomination to which AB and CD have been reduced, as was demonstrated at the beginning of this proposition.

Now, when several fractions are given, the first two are to be added; then this sum is to be joined with the third, and this sum with the fourth, and so on in turn, until all are dealt with.

But if whole numbers are given together with fractions, the whole numbers are to be added separately and the fractions separately.

For example, let $\frac{2}{3}$ and $\frac{3}{4}$ be fractions of this whole number 60. Its $\frac{2}{3}$ is 40, and its $\frac{3}{4}$ is 45. From 40 and 45 the sum 85 arises — that is, the whole integer 60, and 25 units besides, which make $\frac{5}{12}$ of the integer 60 — just as from $\frac{2}{3}$ and $\frac{3}{4}$ the sum $\frac{17}{12}$ is collected, that is, one whole 1 and $\frac{5}{12}$ besides.

Likewise, the sum of the fractions $\frac{1}{3}$ and $\frac{4}{9}$ is $\frac{21}{27}$, that is, in lowest terms $\frac{7}{9}$. So if the whole of those fractions is 36, then $\frac{1}{3}$ of it is 12 and $\frac{4}{9}$ of it is 16; and here you see that 12 and 16 make 28, that is, $\frac{7}{9}$ of the whole 36.

XXI.

To subtract a smaller fraction from a larger.

From the larger fraction AB let the smaller CB be subtracted, and let these fractions first be of the same denomination. When the numerator C of the smaller fraction is subtracted from A, the numerator of the larger, let the remainder be the number D, to which the same denominator B is assigned. I say that the fraction DB is the remainder after the subtraction of the fraction CB from the fraction AB. For since C subtracted from A leaves D, A is composed of C and D. Therefore the fraction AB, whose numerator A is collected from the numerators C and D, is the sum of the two fractions CB and DB, as was shown in the first part of the preceding proposition. Hence, when the fraction CB is subtracted from the fraction AB, the remainder becomes the fraction DB — which was to be proved.

$$AB = 7/10 \quad CB = 3/10 \quad DB = 4/10$$

Next, let the fractions AB and CD have different denominators, and let the smaller CD be subtracted from the larger AB. From C, the numerator of the smaller, into B, the denominator of the larger, form E; and from A, the numerator of the larger, into D, the denominator of the smaller, form F; and let E, taken away from F, leave G, to which is assigned the denominator produced by the mutual multiplication of the denominators. I say that the fraction GH is the remainder after the subtraction of the fraction CD from the fraction AB.

$$AB = 3/4 \times CD = 2/5 \rightarrow E = 8, \quad F = 15, \quad GH = 7/20$$

[Margin: g. Elements VII.17 (17. sept.)] For since D, multiplying A and B, makes F and H, [Margin: h. Prop. II (2. huius)] it follows that A is to B as F is to H. And as A is to B, so is the fraction AB to the whole; therefore also F is to H as the fraction AB is to the whole. Again, since B, multiplying C and D, makes E and H, [Margin: i. Elements VII.17 (17. septi.)] C is to D as E is to H; [Margin: k. Prop. II (2. hui.)] and

as C is to D, so is the fraction CD to the whole; therefore also E is to H as the fraction CD is to the whole. Since, then, E, the first, is to H, the second, as the fraction CD, the third number, is to the whole, the fourth number, [Margin: a. Prop. II (2. huius)] and G, the fifth, is to that same second H as the fraction GH, the sixth number, is to that same whole, the fourth — then, by the fifth theorem of the scholium to Proposition 22 of Book 7 (*Elements* VII.22, schol.), E and G together, the first and fifth, are to H, the second, as the fractions CD and GH together, the third and sixth numbers, are to the whole. And as E and G together are to H, so is F — equal to E and G themselves (for E subtracted from F left G) — to that same H. Therefore also F is to H as the fractions CD and GH together are to the whole. Since, then, it has been shown that as F is to H, so is the fraction AB to the whole, it follows that the fraction AB is to the whole as the fractions CD and GH together are to that same whole; and therefore the fraction AB is equal to the fractions CD and GH together. Hence, when the fraction CD is subtracted from the fraction AB, the remainder is the fraction GH — which was to be proved.

Or thus. Since from the multiplication of the numerators into the denominators crosswise, and from the multiplication of the denominators by one another, there arise two fractions of the same denomination equal to the given fractions — as is established from the demonstration of Proposition 10 — if E, produced from C into B, is subtracted from F, produced from A into D, and to the remaining number G one assigns the common denominator H produced from the denominators, then the fraction GH is produced, the remainder after the subtraction of the fraction CD from the fraction AB, just as was shown at the beginning of this proposition. [Margin: b. Prop. XI (11. huius)]

Now, if whole numbers are given together with fractions, the whole numbers are to be subtracted separately from the whole numbers, and the fraction from the fraction. But if the fraction to be subtracted is larger than the one from which the subtraction ought to be made, one must first reduce one unit of the whole number from which the subtraction is made into a fraction of the denominator of the adhering fraction. For example, if $6\frac{2}{5}$ is to be subtracted from $10\frac{3}{4}$: subtracting 6 from 10 leaves 4, and subtracting $\frac{2}{5}$ from $\frac{3}{4}$ leaves the fraction $\frac{7}{20}$; so the whole remaining number is $4\frac{7}{20}$. But if $4\frac{6}{7}$ is to be subtracted from $20\frac{3}{4}$, we shall make from one unit of the number 20 the fraction $\frac{4}{4}$, which together with $\frac{3}{4}$ makes $\frac{7}{4}$, and 19 whole units remain. Subtracting, then, the whole number 4 from 19 leaves 15; and subtracting the fraction $\frac{6}{7}$ from the fraction $\frac{7}{4}$ leaves the fraction $\frac{25}{28}$. So the whole remaining number is $15\frac{25}{28}$.

For example, let $\frac{3}{4}$ and $\frac{2}{5}$ be fractions of this whole number 40. So if $\frac{2}{5}$ — that is, 16 — is subtracted from $\frac{3}{4}$ — that is, from 30 — then 14 remains, namely $\frac{7}{20}$ of the whole number 40, as the calculation above has shown.

XXII.

To multiply a fraction by a fraction.

Let the fraction AB be multiplied by the fraction CD. From the multiplication of the numerators A and C by one another form E, to which is assigned F, produced from the denominators B and D. I say that the fraction EF is generated from the multiplication of the fractions AB and CD by one another. For let G be formed from E into D, and H from C into F; [Margin: c. Prop. V (5. huius)] then the fraction EF is to the fraction CD as G is to H. And since C, multiplying A and F, makes E and H, [Margin: d. Elements VII.17 (17. septi.)] A is to F as E is to H; and by alternation, A is to E as F is to H. Again, since D, multiplying E and B, makes G and F, then by the perturbed proportion, as appears here, A is to B as G is to H. And as G is to H, so we have shown the fraction EF is to the fraction CD; [Margin: e. Elements VII.17 (17. septi.)] and as A is to B, so is the fraction AB to the whole, that is, to 1. Therefore also the fraction EF is to the fraction CD as the fraction AB is to 1. Hence, by the definition of multiplication, the fraction EF is produced from the multiplication of the fraction AB into the fraction CD [Margin: f. Prop. II (2. huius)] — which was to be proved.

$$H = 60 \quad G = 40 \quad AB = \frac{2}{3} \quad CD = \frac{4}{5} \times EF = \frac{8}{15}$$

Proportion terms: $A \cdot G / E \cdot F / B \cdot H$

But if a fraction is to be multiplied by a whole number, one must assign a unit to the whole number, so that it becomes as it were a fraction whose numerator is the given whole number and whose denominator is unity. From this it follows that it is enough if the numerator of the proposed fraction is then multiplied by the given whole number and the denominator of that same fraction is assigned to the resulting number; because the unit assigned to the whole number, multiplied into the denominator of the given fraction, does not increase that denominator. Thus, if the fraction $\frac{3}{4}$ is to be multiplied by 5, the result is $\frac{15}{4}$, as appears here: $\frac{3}{4} \cdot \frac{5}{1}$. For the fraction $\frac{15}{4}$ is generated.

But if fractions adhere to whole numbers, [Margin: g. Prop. XI (11. huius)] the whole numbers must be brought back to a fraction of the same denomination as the adhering fraction, and from the numerator of this fraction and the numerator

of the adhering fraction a single numerator is formed. Thus, if $7 \frac{2}{3}$ is to be multiplied by $4 \frac{1}{2}$, these become the two fractions to be multiplied: $\frac{23}{3} \cdot \frac{9}{2}$.

Now, to adapt the multiplication of fractions to whole numbers, the fraction produced is not to be compared with the whole number assumed — as was done in addition and subtraction — but with the square of the whole number assumed. For since the comparison must be made between like things, and since from the multiplication of two numbers by one another a plane number is generated, the number produced must be compared with the plane of the whole number, that is, with its square. So let $\frac{2}{3}$ and $\frac{4}{5}$ be fractions of this whole number 60; from their multiplication the fraction $\frac{8}{15}$ is generated. It is necessary, then, that $\frac{2}{3}$ of the number 60, multiplied into $\frac{4}{5}$ of the same, make a number that constitutes $\frac{8}{15}$ of the square produced from 60 into itself. And this is plainly established: for $\frac{2}{3}$ of the number 60 is 40, and $\frac{4}{5}$ of the same is 48; and from 40 into 48 arises the number 1920, which makes $\frac{8}{15}$ of the number 3600, that is, of the square of 60 itself.

XXIII.

To divide a fraction by a fraction.

Let the fraction AB be divided by the fraction CD, and first let the numbers C and D of the latter measure the numbers A and B of the former, by E and F, so that when A is divided by C the quotient is E, and when B is divided by D the quotient is F. I say that the fraction EF is the quotient of the division of the fraction AB by the fraction CD. For since C measures A by E, and D measures B by F, [Margin: h. 9. pron. [?] (degraded abbreviation)] A is generated from C into E, and B from D into F. [Margin: i. Prop. XXII (22. huius)] Therefore the fraction AB is produced from the multiplication of the fraction EF by the fraction CD; and hence, by the definition of multiplication, the fraction AB is to the fraction CD as the fraction EF is to 1. Wherefore, since AB, the divided fraction, is to CD, the dividing fraction, as the fraction EF is to 1, then, by the definition of division, the fraction EF is the quotient of the division of the fraction AB by the fraction CD — which was to be proved.

$$\begin{aligned} AB = 12/16 \div CD = 3/8 \rightarrow EF = 4/2 \quad AB = 6/8 \div CD = 3/8 \rightarrow EF = 2/1 \quad AB = 3/8 \div CD \\ = 3/4 \rightarrow EF = 1/2 \end{aligned}$$

Next, let the numbers C and D of the fraction CD not measure the numbers A and B of the fraction AB. [Margin: k. Prop. XV (15. huius)] Let the fraction AB be reduced to another equal fraction EF, whose numbers E and F the numbers C and D of the fraction CD measure by the numbers G and H, produced from A into D

and from C into B. This will happen if K, produced from C into D, is multiplied into A and B, so that E and F are generated, as was shown in Proposition 15. Since, then, C and D measure E and F by G and H, the fraction GH is the quotient of the division of the fraction EF — or of AB, equal to it — by the fraction CD, as was demonstrated at the beginning of this proposition. Which was to be proved.

$$EF = 24/36 \quad AB = 2/3 \quad K = 12 \quad CD = 3/4 \quad GH = 8/9 \quad EF = 90/135 \quad AB = 6/9 \quad K = 15 \quad CD = 3/5 \quad GH = 30/27$$

But since G and H, the numbers of the quotient fraction GH, are generated from A into D and from C into B, as was said, it is enough — for the division of any fraction by any fraction — that the numerator A of the fraction to be divided be multiplied into D, the denominator of the dividing fraction, and C, the numerator of the dividing fraction, into B, the denominator of the fraction to be divided. For the first number produced, G, will give the numerator, and the second, H, the denominator of the quotient fraction GH. And this is true for all fractions, whether or not the numbers of the fraction to be divided measure the numbers of the dividing fraction. For always, from the numerator of the fraction to be divided into the denominator of the dividing fraction, and from the numerator of the dividing fraction into the denominator of the fraction to be divided, two numbers are produced, by which the numbers of the dividing fraction measure the numbers of the fraction to which the fraction to be divided is brought back according to the doctrine of Proposition 15 — as is clear from the demonstration of that proposition, and as appears in this adjoined example, where the numbers C and D measure the numbers A and B by G and H; and the numbers E and F, produced from A and B into K (the product of C into D), those same numbers C and D measure by L and M. And so both the fraction GH and the fraction LM are the quotient of the fraction AB divided by the fraction CD.

$$EF = 48/54 \quad AB = 8/9 \quad K = 6 \quad CD = 2/3 \quad GH = 4/3 \quad LM = 24/18$$

Now, if a whole number is to be divided by a fraction, or a fraction is to be divided by a whole number, a unit must be assigned to it, so that it becomes as it were a fraction whose numerator is the given whole number and whose denominator is 1. Thus, if the number 8 is proposed to be divided by $\frac{1}{2}$, the quotient is $16/1$, as is clear in the former adjoined example. But if the fraction $\frac{1}{2}$ is to be divided by the whole number 8, the quotient is $1/16$, as appears in the latter example.

$$8/1 \div 1/2 \rightarrow 16/1 \quad 1/2 \div 8/1 \rightarrow 1/16$$

But if fractions adhere to whole numbers, the whole numbers must be reduced to a fraction of the same denomination as the adhering fraction, just as we said at the end of the preceding proposition.

But since it is not easy to keep in memory that the numerator of the quotient fraction is generated from the numerator of the fraction to be divided into the denominator of the dividing fraction, and the denominator from the numerator of the dividing fraction into the denominator of the fraction to be divided, it is better, as an aid to memory, to interchange the places of the numbers of the dividing fraction — as we taught in the *Arithmetic* — and then to apply the rule of multiplication. Thus, if the fraction $\frac{3}{4}$ is proposed to be divided by $\frac{2}{7}$, the numbers of the dividing fraction must be interchanged in this way: $\frac{7}{2}$. Whence the quotient is $\frac{21}{8}$, as you see here. For by this method the numerator of the fraction to be divided is always multiplied into the denominator of the dividing fraction, according to the rule of multiplication, which prescribes that the numerators be multiplied by one another to form the numerator, and so on.

$$\frac{3}{4} \div \frac{2}{7} \rightarrow (\text{interchanged}) \frac{7}{2} \rightarrow \frac{21}{8}$$

Let the whole number be 700, whose fraction $\frac{3}{4}$ is to be divided by $\frac{2}{7}$ of the same — that is, the number 525 by 200. It is plain that, dividing 525 by 200, the quotient is $2 \frac{5}{8}$, that is, the fraction $\frac{21}{8}$, which was just found. So too, if the whole number 10 taken eight times is divided by its half — namely, by 5 — the quotient is 16, which was found above from the division of 8 by $\frac{1}{2}$.

XXIV.

To graft one fraction into another.

Let the fraction AB be grafted into the fraction CD, and let the sense first be that the fraction AB of one part of the fraction CD is to be added to the fraction CD — that is, that $\frac{3}{4}$ of one seventh is to be added to $\frac{6}{7}$. From C, the numerator of the latter fraction, into B, the denominator of the former fraction, form F, to which is added A, the numerator of the former; and to the composite number G assign the denominator H, produced from the multiplication of the denominators B and D. I say that the fraction GH is produced from the grafting of the fraction AB into the fraction CD, in the sense we have described — that is, that the fraction GH is equal to the fraction AB with respect to one part of the fraction CD, added to the fraction CD. [Margin: l. Prop. XIV (14. huius)] For since AB is the fraction of one part of the fraction CD, it is reduced to the simple fraction AH, whose numerator is the same as A (produced, namely, from unity into A), while its denominator is the number H, produced from the denominators B and D, as appears in this

adjoined example. Likewise, the fraction FH is equal to the fraction CD, having the same denominator H produced from the denominators B and D, and the numerator F produced from C, the numerator of the latter fraction, into B, the denominator of the former: (for since B, into C and D, makes F and H, [Margin: m. Elements VII.17 (17. septi.)] C is to D as F is to H, [Margin: n. Prop. VIII (8. huius)] and therefore the fractions CD and FH are equal). Thus it is brought about that the fraction GH, whose numerator G is composed of the numerators F and A of the fractions FH and AH (namely, from the number produced from C into B, and from A,)...

$$F = 24 \quad AB = 3/4 \quad CD = 6/7 \quad GH = 27/28$$

$$AB = 3/4 \text{ (one seventh)} \quad 1/7 \quad AH = 3/28$$

(from A). Let the denominator be H — the same denominator as those fractions FH and AH. Then, I say, the fraction GH is the sum of the fractions FH and AH, as was shown at the beginning of Prop. 20. That is, it is the sum gathered from the fraction AB (with respect to one part of the fraction CD), which was shown equal to the fraction AH, and from the fraction CD, which was shown equal to the fraction FH. The fraction GH is therefore produced by grafting the fraction AB into the fraction CD; that is, it equals the fraction AB of one part of the fraction CD, taken together with the fraction CD itself. Which is what was proposed.

Now suppose that several fractions AB, CD, EF, GH are to be inserted — that is, that the fraction AB (of one part of CD, of one part of EF, of one part of GH), and the fraction CD (of one part of EF, of one part of GH), and the fraction EF (of one part of GH) are to be added to the fraction GH. Then one must proceed as follows. From G, the numerator of the last fraction GH, multiplied into F, the denominator of the second-to-last fraction EF, form a number, and to it add E, the numerator of that same second-to-last fraction EF, to make the number K. Next, to the product of K into D, the denominator of the third-from-last fraction CD, add C, the numerator of that same fraction CD, to make M; and to the product of M into B, the denominator of the immediately preceding fraction AB, add A, the numerator of that same fraction AB, to make P. And so on continually: always multiply the number last formed into the denominator of the immediately preceding fraction, and to the product add the numerator of that same immediately preceding fraction, until no fraction remains. Then, under the number P — the one formed at the last step — set the number Q, produced by multiplying the denominators together: first multiply H into F to make L, then L into D to make N, then N into B to make Q, and so on. I say that the fraction PQ is produced by grafting the given fractions, in the sense we have explained.

$K = 14$ $M = 59$ $P = 119$ $A/B = 1/2$ $C/D = 3/4$ $E/F = 2/3$ $G/H = 4/5$ $L = 15$ $N = 60$ $Q = 120$

For, as was shown in the case of two fractions, the fraction KL is produced by grafting the fraction EF into the fraction GH ; that is, it equals the sum gathered from the fraction EF (of one part of GH) and from the fraction GH . Next, the fraction CD of one part of EF , of one part of GH ,

[Margin: d — 14. huius (Prop. XIV of this treatise)]

makes a simple fraction whose numerator is C (namely, the product of C into unity taken twice, thus: 3.1.1.), and whose denominator is N , produced from D into L — that is, from the multiplication of the denominators H , F , D .

[Margin: e — 8. huius (Prop. VIII of this treatise)]

Likewise the fraction whose numerator is the number produced from D into K , and whose denominator is the same number N , produced from D into L , equals the fraction KL ,

[Margin: f — 17. septi. (Elements VII.17)]

because the numerators of these fractions bear the same ratio to the denominators; for D multiplied into K and into L generates the numbers of one and of the other fraction. Therefore, since — by what we demonstrated at the beginning of Prop. 20 — the fraction MN (whose numerator M is formed from the numerator C and from the number produced by D into K) equals the sum gathered from the fraction whose numerator is C and whose denominator is produced from D into K , and from the fraction whose denominator is N ; the same fraction MN will also equal the sum gathered from the fraction GH , from the fraction EF (of one part of GH), and from the fraction CD (of one part of EF , of one part of GH).

Again, the fraction AB of one part of CD , of one part of EF , of one part of GH ,

[Margin: g — 14. huius (Prop. XIV of this treatise)]

makes a simple fraction whose numerator is A , and whose denominator is Q , produced from B into N — that is, from the multiplication of the denominators H , F , D , B .

[Margin: h — 8. huius (Prop. VIII of this treatise)]

Likewise the fraction whose numerator is the number produced from B into M, and whose denominator is that same number Q, produced from B into N, equals the fraction MN,

[Margin: i — 17. septi. (Elements VII.17)]

because the numerators of these fractions bear the same ratio to the denominators; for B multiplied into M and into N generates the numbers of one and of the other fraction. Therefore, since the fraction PQ (whose numerator P is formed from the numerator A and from the number produced by B into M) equals — by what was demonstrated at the beginning of Prop. 20 — the sum gathered from the fraction whose numerator is A and whose denominator is Q, and from the fraction whose numerator is generated from B into M and whose denominator is the same Q; the same fraction PQ will also equal the sum gathered from the fraction GH, from the fraction EF (of one part of GH), from the fraction CD (of one part of EF, of one part of GH), and from the fraction AB (of one part of CD, of one part of EF, of one part of GH). Which is what was proposed. And the reasoning is the same for still more fractions.

Now suppose the sense is that the fraction AB *of the whole* fraction CD is to be added to the fraction CD.

[Margin: k — 14. hui. (Prop. XIV of this treatise)]

From C, the numerator of the latter fraction, multiplied into B, the denominator of the former, make F; to it add E, produced from the numerators A and C; and with the number G thus formed, set H, produced from the denominators B and D. I say that the fraction GH is produced by grafting the fraction AB into the fraction CD, in the sense we mentioned — that is, that the fraction GH equals the sum gathered from the fraction CD and from the fraction AB of the fraction CD.

[Margin: l — 8. huius (Prop. VIII of this treatise)] [Margin: m — 17. sept. (Elements VII.17)]

$$E = 18 \quad F = 24 \quad A/B = 3/4 \quad C/D = 6/7 \quad G = 42 \quad H = 28$$

For since the fraction AB (of the) fraction CD reduces to the simple fraction EH, whose numerator is E, produced from the numerators A and C — as the appended example shows — the fraction GH (which, by what we showed at the beginning of Prop. 20, equals the sum of the fractions EH and FH) is equal to the sum gathered from the fraction CD (that is, from the fraction FH) and from the fraction AB of the fraction CD (that is, from the fraction EH). And therefore the

fraction GH is produced by grafting the fraction AB into the fraction CD, in this latter sense. Which is what was proposed.

$$A/B = 3/4 \quad C/D = 6/7 \quad E/H = 18/28 \quad F/H = 24/28$$

But if several fractions AB, CD, EF, GH are to be inserted — that is, if the fraction AB (of the fraction CD, of the fraction EF, of the fraction GH), and the fraction CD (of the fraction EF, of the fraction GH), and the fraction EF (of the fraction GH) are to be added to the fraction GH — then one must proceed as follows. Multiply G into F, and to the product add the number produced from E into G, to make K. Next multiply K into D, and to the number produced add the number made from C, E, G, to make M. Then, to the product of M into B, add the number produced from A, C, E, G, to make P. And so on continually: always multiply the number last generated into the denominator of the preceding fraction, and to the number produced add the number formed from all the numerators of the fractions taken up to that point, until no fraction remains. Then, under the number P — the one produced at the last step — set the number Q, produced from all the denominators, as in the former sense. I say that the fraction PQ is produced by grafting the said fractions, provided the grafting is understood as stated. For, as was demonstrated in the case of two fractions, the fraction KL is produced by grafting the fractions EF, GH — that is, it equals the sum gathered from the fraction EF (of the whole fraction GH) and from the fraction GH.

$$P = 232 \quad M = 104 \quad K = 20 \quad A/B = 1/2 \quad C/D = 3/4 \quad E/F = 2/3 \quad G/H = 4/5 \quad Q = 120 \quad N = 60 \quad L = 15$$

from the fraction GH. Next, the fraction CD of the whole fraction EF, of the whole fraction GH,

[Margin: m — 14. hui. (Prop. XIV of this treatise)]

makes a simple fraction whose numerator is produced from the numerators C, E, G, and whose denominator is N, produced from the denominators H, F, D.

Likewise the fraction whose numerator is the same N, produced from D into L — that is, from the denominators H, F, D —

[Margin: n — 8. huius (Prop. VIII of this treatise)]

equals the fraction KL,

[Margin: o — 17. sept. (Elements VII.17)]

because the numerators of these fractions bear the same ratio to the denominators; for D multiplied into K and into L makes the numbers of one and

the other of these fractions. Therefore, since the fraction MN (whose numerator M is formed from the number that the numerators C, E, G generate, and from the number that D into K produces) equals — by what was shown at the beginning of Prop. 20 — the sum gathered from the fraction whose numerator is produced from the numerators C, E, G and whose denominator is N (produced from the denominators H, F, D), and from the fraction whose numerator is generated from D into K and whose denominator is the same N; the same fraction MN will also equal the sum gathered from the fraction GH, from the fraction EF (of the fraction GH), and from the fraction CD (of the fraction EF, of the fraction GH).

Again, the fraction AB of the fraction CD

[Margin: p — 14. huius (Prop. XIV of this treatise)]

makes a simple fraction whose numerator is produced from the numerators A, C, E, G, and whose denominator is produced from the denominators H, F, D, B. Likewise the fraction whose numerator is produced from B into M

[Margin: q — 8. huius (Prop. VIII of this treatise)]

equals the fraction MN,

[Margin: r — 17. septi. (Elements VII.17)]

because the numerators of these fractions bear the same ratio to the denominators; for B multiplied into M and into N makes the numbers of one and the other of this fraction. Therefore the fraction PQ (whose numerator P is formed from the number that the numerators A, C, E, G generate, and from the number that B into M makes) — since it equals, by what was demonstrated at the beginning of Prop. 20, the sum gathered from the fraction whose numerator is produced from the numerators A, C, E, G and whose denominator is Q, and from the fraction whose numerator is generated from B into M and whose denominator is the same Q — will also equal the sum gathered from the fraction GH, from the fraction EF (of the fraction GH), from the fraction CD (of the fraction EF, of the fraction GH), and from the fraction AB (of the fraction CD, of the fraction EF, of the fraction GH). Which is what was proposed. And the reasoning is the same for more fractions.

P = 232 M = 104 K = 20 A/B = 1/2 C/D = 3/4 E/F = 2/3 G/H = 4/5 Q = 130 [?] N = 60
L = 15

On the Composition of Proportions [De proportionum compositione]

Having dispatched what pertains to the demonstrations concerning fractional numbers, it remains for us to explain the composition of proportions — which we undertook, at this place, to treat in connection with Def. 10 of Book 5, Def. 5 of Book 6, and Prop. 23 of Book 6. First, then, that "composition" of proportions with which Euclid dealt in Def. 10 of Book 5 and Def. 5 of Book 6 — in those propositions where he demonstrates a doubled, tripled, or compounded proportion of magnitudes or of numbers — is not a true addition of proportions, such that the doubled or tripled proportion would be twice or three times greater than the proportion of which it is called the double or triple. Likewise, that a proportion compounded of several proportions is truly some whole whose parts are the proportions of which it is said to be composed — as most interpreters of Euclid suppose — can be plainly disproved from this: that a part would then be either equal to, or greater than, the whole. For since this composition must be understood whether a greater quantity is compared with a lesser or a lesser with a greater (as we showed at Def. 10 of Book 5), suppose that, given the three continually proportional terms 1, 10, 100, the proportion $1 : 100$ were not only called the double of the proportion $1 : 10$ (as Def. 10 of Book 5 intends), but were truly twice as great — so that it were heaped up out of the two equal proportions $1 : 10$ and $10 : 100$, as Euclid's interpreters suppose. Then who does not see that the part would be greater than the whole? — namely, that the proportion $1 : 10$, which is one part, would be greater than the proportion $1 : 100$. And here, [in the case] 4.4.4 [?], that the part would be equal to the whole? So too, if — given the three terms 4, 2, 8, which are not continually proportional — the proportion $4 : 8$ were truly heaped up out of the proportions $4 : 2$ and $2 : 8$ as out of parts (as those same authors contend), then the part would again be greater than the whole, since the double proportion $4 : 2$ is greater than the sub-double proportion $4 : 8$. And here, [given] 10, 5, 1, 2, 5, the part would be equal to the whole — namely, the proportion $10 : 5$.

24. | 48. 12.2. | 3.16.

to concede in any way, willing or unwilling, from Prop. 5 of Book 8. For let there be two plane numbers, 24 and 48. Let the sides of the former be 12 and 2; of the latter, 3 and 16. Since, then, Euclid there demonstrates that the proportion $24 : 48$ is compounded of the proportions of the sides — that is, of the proportion $12 : 3$ and of the proportion $2 : 16$ — it will be a component part (if this composition is a true addition), namely the sub-double proportion $24 : 48$. By like reasoning, if the

proportion $24 : 48$ is truly a whole, and its component parts are the quadruple proportion $12 : 3$ and the sub-octuple proportion $2 : 16$, then if either of these be subtracted from it, the other will remain. Therefore the greater can also be subtracted from the lesser — namely, the quadruple proportion $12 : 3$ subtracted from the sub-double proportion $24 : 48$, from the proportion $2 : 16$ — and the remainder will be the quadruple proportion $12 : 3$, greater than that from which the subtraction was made. And if, of the latter plane number 48, the sides be taken as 12 and 4, one of the components — namely the proportion $2 : 4$ — will be equal to the whole proportion, that is, to $24 : 48$. And with the proportion $2 : 4$ subtracted, there would still remain the proportion of equality $12 : 12$, which is greater than the whole, that is, than the proportion $24 : 48$. Again it would follow that the whole is not increased even if infinite parts were added to it. For, given these four terms 12, 4, 2, 1, if the proportion $12 : 1$ is truly heaped up out of the proportions $12 : 4$, $4 : 2$, and $2 : 1$ as out of parts, so that these proportions taken together equal the proportion $12 : 1$: if with those terms there are contained a further three terms in this way, 12, 4, 2, 1, 6 — of which the first three are the same as those out of which the proportion was previously composed — then the three proportions $1 : 6$, $6 : 3$, and $3 : 1$, added to the three proportions $12 : 4$, $4 : 2$, and $2 : 1$, do not increase the whole heaped up out of them.

All these consequences are absurd and contrary to the principles of mathematicians. Add to this that two triple proportions [compounded] constitute a sextuple proportion, not a nine-fold one — as the said authors would have it, when a triple proportion is called "tripled doubled," as appears in these numbers, 9.3.1. For who does not see that, if some agent be as 3, that same one is made twice as powerful as 6, not as 9? So too the common understanding grasps that, from a triple and a quintuple, an octuple proportion is produced, because two motive powers — as 3 and as 5 — moving together move as 8, and do not constitute out of themselves the proportion $15 : 1$, [p. 393] even though this [p. 393]

is said to be composed of them, from Def. 5 of Book 6, as is clear in these numbers, 15.5.1. Add to this that the powers of many agents cannot be halved, because between two numbers that express the proportion of the agent to the patient, no proportional mean falls. For example: an agent as 6 could not have an agent half as powerful, because between 6 and 1 no proportional mean number falls; whereas who would not at once understand that an agent as 3 is less, in double proportion, than an agent as 6?

It is clear, then, that a composition of this kind of proportions is not addition, but a *continuation* of proportions, brought about by the multiplication of the denominators, as we demonstrated at Def. 5 of Book 6 — where we also explained why the proportion of the extremes is said to be composed of the mean proportions, on account of the continuation of the terms; just as at Def. 10 of Book 5 we explained why, when three, four, or more continually proportional terms are set out, the proportion of the extremes is called the double, triple, or quadruple (and so on) of the proportion which the first two terms hold. These matters will be perceived more plainly from what we are now about to say concerning the *true* composition of proportions.

Accordingly, all the arithmetical operations on proportions — namely addition, subtraction, multiplication, and division — must be carried out by means of the denominators of the proportions, as Voluminius Rodulphus [?] rightly teaches in his disputation on the proportion of proportions. And since the denominators of proportions are fractions, or *minutiae* (as we taught in Book 5) — for under the denominator of any multiple proportion, which is a whole number, a unit can be supplied, so that it becomes, as it were, a fraction denominated from unity — each of which equals the fraction that any two numbers constitute in the proportion of which that fraction is the denominator (if the numerator is made from the antecedent and the denominator from the consequent): it plainly follows that the arithmetical operations on proportions do not differ from the operations on fractional numbers, whether they are set up by means of the denominators of the proportions or by means of any numbers whatever of those same proportions — provided the consequent terms are placed under the antecedents, in the manner of fractions, as Cardanus [Cardano] excellently prescribed in his *Arithmetic*, as will now appear.

First, let two proportions be gathered into one sum — the triple and the quintuple, 3 and 5 — from whose addition arises the sum 8; an octuple proportion will be heaped up out of them.... supposing first a unit under each of them, let [the numerators] be added in the manner of fractions; or let the numbers between which the given proportions are found be gathered into one sum, just as if they were fractional numbers, with the consequent terms placed under the antecedents.

$3/1 \times 5/1 \rightarrow 8/1$ $12/4 \times 40/8 \rightarrow 256/32$ $18/7 \times 3/2 \rightarrow 57/14$ $54/21 \times 6/4 \rightarrow 342/84$

For by the former method the proportion 8 : 1 is gathered, and by the latter 256 : 32, each of which is octuple. So too, from the double-superquadrupartient-sevenths proportion and the sesquialter — whose denominators are $2\frac{4}{7}$ and 1

1/2, and which are found between the numbers 54, 21 and 6, 4 — arises the quadruple-sesquifourteenth proportion, such as both the numbers 57, 14 and 342, 84 hold. But when the operation is set up by means of the denominators, the denominators must first be brought back to single fractions, as was done here; for we brought $2\frac{4}{7}$ back to $\frac{18}{7}$, and $1\frac{1}{2}$ to $\frac{3}{2}$. And this must be understood in the other operations as well.

Next, if from the octuple proportion the triple proportion be subtracted, and likewise from the quadruple-sesquifourteenth proportion the sesquialter proportion be deducted, the remainders will be the quintuple proportion and the double-superquadripartient-sevenths proportion, as is here evident:

$$8/1 \times 3/1 \rightarrow 5/1 \quad 256/32 \times 12/4 \rightarrow 640/128 \quad 57/14 \times 3/2 \rightarrow 72/28 \quad 342/84 \times 6/4 \rightarrow 864/336$$

Third, if the triple proportion is to be multiplied by 2 — or, what is the same, by the double proportion — and likewise the sesquialter proportion by the supertripartient-fifths, the operation must be set up as you see here; there the sextuple proportion will be produced, but here the double-superbipartient-fifths:

$$3-2 / 1-1 \rightarrow 6/1 \quad 12-10 / 4-5 \rightarrow 120/20 \quad 3-8 / 2-5 \rightarrow 24/10 \quad 9-16 / 6-10 \rightarrow 144/60$$

Fourth and last, if the sextuple proportion be proposed to be divided by the triple proportion, and likewise the double-superbipartient-fifths proportion by the sesquialter proportion: if the terms of the divisor be transposed (as we taught in the division of fractions), the operation will be set up thus:

$$6-1 / 1-3 \rightarrow 6/3 \quad 120-4 / 20-12 \rightarrow 480/240 \quad 24-2 / 10-3 \rightarrow 48/30 \quad 144-6 / 16[?]-9 \rightarrow 864/540$$

You see, then, that the arithmetical operations on proportions differ in nothing from the operations on fractions, except that in proportions it is not necessary to interpose a small line between the numerator and the denominator, as it is with fractions.

Now we shall demonstrate, in the following way, that the multiplication of proportions we have prescribed — which the authors falsely call "addition" — agrees with the composition of proportions treated by Euclid in Def. 10 of Book 5 and Def. 5 of Book 6, and that consequently that Euclidean composition is truly a multiplication and not an addition, as we said. Let there be two proportions, $A : B$ and $C : D$, whether equal or unequal. Multiply A , the antecedent, into the antecedent C , and let E result; and from B , the consequent, into the consequent D , let F result. I say...

[The demonstration continues from the previous page — that Euclid's composition of proportions is in truth multiplication (of the quotients), not addition.]

I say that the proportion $E:F$, which is produced by that multiplication, is composed of the two proportions $A:B$ and $C:D$; so that, if these proportions $A:B$ and $C:D$ are equal, the proportion $E:F$ is called the duplicate [i.e. squared] ratio of either of them, as def. 10 of Book V requires:

A, 6. C, 12. B, 2. D, 4. | A, 3. C, 6. B, 2. D, 5.
E, 72. F, 8. G, 24. | E, 18. F, 10. G, 12.

But if they are unequal, it is said to be composed of them, according to the sense of def. 5 of Book VI. For let G be made from B into C . And since from A and B into C there are produced E and G [that is, $E = A \times C$, $G = B \times C$], [Margin: a — Elem. VII.18] it follows that as $A:B$, so $E:G$. Again, since from B into C and D there are produced G and F , [Margin: b — Elem. VII.17] it follows that as $C:D$, so $G:F$. Now the proportion $E:F$ is composed of the proportions $E:G$ and $G:F$, by Euclid's definition. Therefore the same proportion $E:F$ is composed of the proportions $A:B$ and $C:D$, since these are the same as $E:G$ and $G:F$. This is also evident from the demonstration which we brought forward, at the definition in Book VI, from Eutocius and Witelo [Vitellio]. For since the composition of proportions described by Euclid answers to the multiplication of the denominators [quotients] among themselves, as we there demonstrated, while our own multiplication does not differ from the multiplication of the denominators, it is plainly established that that composition of proportions is the multiplication which we have set forth.

By the same reasoning we shall show that the subtraction of proportions, which these same authors teach, is nothing other than the division we have explained, and that it is the contrary of that composition of Euclid. For let the proportion $C:D$ be subtracted from the proportion $A:B$, as they will have it. Let E be made from A into D , and F from B into C — which is the same as if the terms of the proportion $C:D$ were to exchange places and the rule of multiplication were applied. I say that the proportion $E:F$, which is produced by the division of the proportion $A:B$ by the proportion $C:D$, as we have taught,

A, 9. C, 3. B, 1. D, 1. | A, 4. C, 6. B, 2. D, 2.
E, 9. F, 3. G, 27. | E, 8. F, 12. G, 24.

is that which is left over when the proportion $C:D$ is taken away from the proportion $A:B$: that is, that the proportion $A:B$ is composed of the proportions $C:D$ and $E:F$, in accordance with Euclid's definition. For let G be made from A into C . Since, then, from A and B into C there are produced G and F [$G = A \times C$, $F = B \times C$],

[Margin: c — Elem. VII.18 (printed "1."; apparently a misprint for 18, parallel to note a)] it follows that as $A:B$, so $G:F$. Again, since from A into C and D there are produced G and E , [Margin: d — Elem. VII.17] it follows that as $C:D$, so $G:E$. Since therefore [$G:F$ is composed] of $G:E$ and $E:F$, as Euclid will have it, the proportion $A:B$ also (which is the same as $G:F$) will be composed of the same proportions $G:E$ — that is, $C:D$ — and $E:F$; and accordingly, when the proportion $C:D$ is subtracted from the proportion $A:B$, the proportion $E:F$ will remain: just as, if from the proportion $G:F$ (with the term E placed in the middle) the proportion $G:E$ is taken away, the proportion $E:F$ is left. But who does not see that this is rather to *divide* the proportion $A:B$ by the proportion $C:D$, than to *subtract* the proportion $C:D$ from the proportion $A:B$ — lest one be said to take a greater away from a lesser, as happens in the latter example? And so much for the composition of proportions. Whoever desires more, let him read the most learned treatise written on this subject by Volumnio Rodolfo of Spoleto [Volumnius Rodolphus Spoletanus].

FINIS ELEMENTI NONL [recte: NONI — "End of the Ninth Book"]

Euclid's Tenth Book [EVCLIDIS ELEMENTVM DECIMVM]

Definitions

I.

Commensurable magnitudes are said to be those which the same measure measures.

Euclid, in the three preceding books, has finished with the matters that concern numbers, so far as seemed enough for the understanding of geometrical things. Now, in this tenth book, he proceeds to the discussion of commensurable and incommensurable lines — for whose sake, as we said above, he undertook the treatment of numbers. For without a knowledge of these lines, very many magnitudes, both solid and plane, can neither be perfectly understood nor, when occasion demands, be applied to practical work and use; because for the most part their sides are incommensurable. The same may be said of planes and solids themselves, since these too are very often incommensurable, as we shall demonstrate toward the end of this book. But since this book is beset with many difficulties, on account of the obscurity of the lines it treats of, I shall bend every sinew of my industry to this end: that, out of what has hitherto been demonstrated by Euclid, it may be made so plain and easy that it can be grasped

without much labor by anyone who has rightly understood the demonstrations of the preceding books. For I cannot side with the opinion of those who think that, for understanding it, that part of arithmetic is necessary which treats of the roots of numbers, both rational and irrational, as they call them. On the contrary, I am wholly persuaded that a perfect knowledge of that part of arithmetic depends upon this tenth book — so far am I from thinking that the treatment of roots is required in order that this book may be more easily understood. Yet I would not deny that one who has mastered the theory of roots and their calculation will grasp this book with greater pleasure than one wholly ignorant of them, because the former can turn the demonstrations to practical use, the latter by no means. It was for this reason, indeed, that we too fitted the first ten theorems of the second book to numbers, so that the studious reader might take from it the greater delight of mind, and profit — not, however, that we supposed the things demonstrated in that book could be more easily understood from numbers. Why then (someone will say) did you not, as in that book, likewise here make use of the numerical examples that Algebra employs, so that the matter might be both more pleasant and more convenient for readers? The reason we thought it should be omitted is ready to hand. For since very few at this time are acquainted with that most celebrated art of Algebra, those numbers, if they were brought in, seemed likely to spread darkness rather than to yield any greater light and clarity; so that the minds of the studious, instead of the help and light which we labor to bring them by these our commentaries, would meet with more inconvenience, and would perceive the demonstrations less well. This could not happen in the second book, since scarcely anyone is ignorant of the addition and multiplication of whole numbers, which alone were needful there. To this is added that those versed in Algebra can, with little trouble, fit the demonstrations of this book to numbers by themselves, whenever they wish — especially since this very thing was accomplished, not long before, carefully and accurately, by Michael Stifel [Michael Stifelius], the noble arithmetician, in the second book of the work which he entitled *Arithmetica Integra*.

And so, to return to our purpose: Euclid, beginning the subject itself in his usual manner from the explanations of the terms he will need, declares in the first place what magnitudes are called commensurable, defining them to be those which the same measure measures. Thus two magnitudes A, B, which the same measure C measures (for C measures A when repeated four times, and B when taken three times), are called commensurable:

Diagram. In the margin stand three horizontal straight lines, one above another, illustrating the definition.

- A (top line): the longest of the three; the common measure c is contained in it four times ("repeated four times"), so that $A = 4 \times c$. Marked off internally by short cross-strokes.
- B (middle line): shorter than A; the common measure c is contained in it three times ("taken three times"), so that $B = 3 \times c$. Also marked off internally.
- c (bottom line): the shortest, serving as the common measure of both A and B.

In the same way, a line of 20 palms and a line of 13 palms are commensurable, because a line of one palm, or of half a palm, or of a third part of a palm, and so on, measures them. Similarly, those surfaces are called commensurable which one and the same surface measures; and likewise those bodies, or solids, are commensurable which the same body or solid measures.

II.

But incommensurable [magnitudes] are those for which no common measure can be found.

Such magnitudes are the diameter of any square and its side; for they have no common measure, as will be demonstrated by Euclid in the last proposition of this book. There are also very many other incommensurable lines, for which no common measure can in any way be given; many of which the Geometer explains in this book, teaching by what method they can be found. Again, those surfaces will be called incommensurable, and those solids incommensurable, which admit no common measure.

III.

Straight lines are commensurable in square [potentia] when the same space measures their squares.

Of straight lines, some are commensurable in length — those, namely, which another line, serving as a common measure, measures; such as those which, in the exposition of def. 1, we called simply commensurable. But some are incommensurable in length — those, namely, which no line, serving as a common measure, measures. Again, of the lines that are incommensurable in length, some are such that their squares are commensurable, while others are so disposed that their squares too are incommensurable. Therefore those lines, incommensurable in length, whose squares are commensurable, are here called by Euclid commensurable in square [power]; because, namely, according to their powers —

that is, according to their squares (for the power of any line is, as we said at prop. 47 of Book I, the square described upon it) — they are commensurable, although in respect of length they are altogether incommensurable.

But if anyone should ask why Euclid defined separately the lines commensurable in square, but not those commensurable in length, the answer is that lines commensurable in length have been more than sufficiently explained in the definition of commensurable magnitudes, since one common measure measures lines of this kind, as has been said. But since no common measure can measure lines commensurable in square, but only their squares measure the same space, it was therefore altogether necessary that these should be set out by their own proper definition.

IV.

But [straight lines are] incommensurable [in square] when no space can be found for their squares that would be their common measure.

The remaining lines, incommensurable in length, whose squares also are incommensurable, he calls incommensurable in square [power]. Now lines commensurable both in length and in square have this, as it were, agreement and connection among themselves: that lines commensurable in length are also commensurable in square, so that no lines can be given commensurable in length without their squares being commensurable also; because the square described from their common measure measures, as a common measure, their squares — as appears in the figure set below. For just as the straight line AB measures the straight lines CD, EF, so also the square AG measures the squares CH, EI. But it is not [conversely the case] that all lines commensurable in square are also commensurable in length; for many lines are commensurable in square — that is, have commensurable squares — which nevertheless are altogether incommensurable in length, as will be demonstrated in this book. Again, among lines incommensurable both in length and in square, this connection is found: that all lines incommensurable in square are also incommensurable in length; but not, conversely, that all lines incommensurable in length are also incommensurable in square, since many lines are found incommensurable in length among themselves while nevertheless in square — that is, according to their squares — they are commensurable. All of which will be clear from the corollary of prop. 9 of this book.

Diagram. Three squares stand side by side on three collinear base-segments, illustrating that lines commensurable in length have squares commensurable in area.

- E–F (leftmost, largest base-segment): the square erected upon it has its far upper corner at I; this is the square EI. It is subdivided internally by rules into an integer number of copies of the unit square AG.
- C–D (middle base-segment): the square erected upon it has its far upper corner at H; this is the square CH, likewise subdivided into copies of the unit square.
- A–B (rightmost, smallest base-segment): the square erected upon it has its far upper corner at G; this is the square AG, the unit square, which serves as the common measure of the squares CH and EI.
- The base-segment AB is the shortest and serves as the common measure of the segments CD and EF.

V.

These things being laid down, it is shown that, for any proposed straight line, there are straight lines infinite in multitude both commensurable and incommensurable with it — some in length and in square, others in square only. And let the proposed straight line be called Rational.

If any straight line of known magnitude is proposed, then of all the others that are compared with it, some will be commensurable with it in length and in power, some in power only; and likewise some will be incommensurable with it in length only, others in both length and power — as will be demonstrated in various places in this tenth book. For Euclid does not intend that it be shown, or gathered, from what has been said (although his words seem to sound this way) that these things are so; but he only indicates and hints to us, in a certain manner, that some lines can be said to be commensurable with the proposed straight line in length and in power, others in power only, and so on. Which indeed in no way follows from what has been said, but will be demonstrated in what follows, as we have said.

Now that proposed line, by reference to which the others are commensurable or incommensurable, is called by the Greeks ῥητή [Greek: ῥητή (rhētē, "rational, expressible")], and by the Latins Rationalis [rational]; because it is always posited as fixed and known, whereas the others, when compared with it, are not always known — although each, taken separately, is likewise fixed and known — since any of them can be divided into however many equal parts you please.

VI.

And those commensurable with it, whether in length and in power, or in power only, [are] Rational.

He teaches that the other lines, commensurable in whatever way with that one which is called Rational, are likewise called Rational — not indeed by position, as that one is, but because, being compared with it, they are found commensurable with it either in length and in power, or in power only.

Therefore, in Euclid's view, the square root of this number 20 or 1000 and the like — or, what comes to the same, a straight line whose square is 20 or 1000 and so on — is called Rational, because in power it is commensurable with the Rational line (for both 20 and 1000 are commensurable with any square number, such as 16, 100, and the rest), even though in length it is incommensurable with it. And so not a few arithmeticians are deceived, who for this reason call such a root irrational, on the ground that it cannot be expressed by a number.

VII.

But those [lines] incommensurable with it, let them be called Irrational.

Since in the preceding definition Euclid called Rational those lines that are commensurable with the assigned Rational straight line either in length and in power, or in power only, it is clear that here he calls Irrational those that are incommensurable with the assigned Rational straight line in both ways — that is, both in length and in power — and not in length only. From this it is also evident that the square root of this number 20 or 1000 and the like — or, what is the same, the line whose square is 20 or 1000 and so on — cannot be called Irrational, since it is incommensurable with the assigned Rational line not in length and in power, but only in length.

VIII.

And let the square that is formed on the assigned straight line be called Rational.

Just as that line which is laid down as fixed and known is called Rational, so too the square described upon it is called Rational, because it likewise is fixed and known; and it is by comparison with it that other areas are called commensurable or incommensurable.

IX.

And those areas commensurable with it, indeed, are Rational.

All plane areas commensurable with the square of the assigned Rational line are called Rational — not by position, as that square is, but because, when compared with it, they are found to be either commensurable or incommensurable with it; just as lines commensurable in any way with the Rational line are likewise called Rational. And since lines whose squares are these areas commensurable with the square of the assigned Rational line [*lineae potentes ipsa spatia* — the sides of squares equal to those areas] are at least commensurable in power with the Rational line — by Definition 3 — it is clear that they too are called Rational, according to Definition 6.

X.

But those [areas] incommensurable with it, let them be called Irrational.

In just the same way, plane areas incommensurable with the square described on the Rational line are called Irrational, exactly as the lines that are wholly incommensurable with the assigned Rational line have been called Irrational.

XI.

And [let] the straight lines that can produce them [be called] Irrational: if those [areas] are squares, [their] very sides; but if any other rectilinear figures, [then] the straight lines that describe squares equal to those incommensurable areas.

He calls Irrational the lines which can produce areas incommensurable with the square of the Rational line, just as he called those areas themselves Irrational: so that, if the incommensurable areas are squares, their sides are called Irrational; but if they are not squares but any other rectilinear figures, then the straight lines that describe squares equal to those incommensurable areas are called Irrational.

It is inferred, moreover, from Definition 7, that the lines which can produce areas incommensurable with the square of the Rational line must be called Irrational — just as above, from Definition 6, we inferred that the lines which can produce areas commensurable with the square of the Rational line must be called Rational. For the lines which can produce those areas incommensurable with the same square of the Rational line are, by Definition 4, incommensurable in power with the Rational line. Therefore, since all lines incommensurable in power are

also incommensurable in length — as we said at Definition 4, and as will be demonstrated in the corollary to Proposition 9 — it is evident, from Definition 7, that those lines which can produce areas incommensurable with the square of the Rational line are called Irrational.

It must also not be passed over that Euclid and the ancient geometers almost always attach the phrases "in length and in power" and "in power only" to the words "commensurable" and "incommensurable," but scarcely ever — very rarely — to the words "Rational" and "Irrational." For lines are rightly said to be commensurable in length and in power, or in power only; and likewise incommensurable in length and in power, or in length only. But it is less correct to speak of them as Rational in length and in power, or in power only, or as Irrational in length and in power, or in length only. And because Campanus did not notice this, he gave many an occasion to speak variously and obscurely, in this tenth book, about commensurable and incommensurable lines, as well as about Rational and Irrational ones.

To these definitions we shall add one postulate, and a few axioms whose use is found in this book.

POSTULATE, OR REQUEST

Let it be postulated that any magnitude can be multiplied so many times over that it exceeds any [given] magnitude of the same kind.

For if two unequal magnitudes of the same kind are given, then — since the greater is not infinite, while the lesser can be increased without limit — it is clear that the lesser can be multiplied so many times that it surpasses the greater. This is also established from what we wrote

at Definition 5 of Book 5. For there we said that magnitudes are to be reckoned of the same kind only when either one of them can be so multiplied that it exceeds the other. And it was from the failure of this condition that we showed a rectilinear angle and an angle of contact [angulus contactus] to be of different kinds.

AXIOMS, OR COMMON NOTIONS

I.

A magnitude that measures any number of magnitudes also measures the magnitude composed of them.

II.

A magnitude that measures any magnitude also measures every magnitude which that one measures.

III.

A magnitude measuring a whole magnitude and a part taken from it also measures the remainder.

These axioms, insofar as they concern numbers, were demonstrated by us in the last three common notions of Book 7. Since the same reasoning holds for magnitudes, there is no point in pointlessly repeating their demonstrations here — especially since they can be carried over word for word, changing only the word "number" into the word "magnitude."

Moreover, since in this book we had to depart from the numbering that Theon follows in the propositions of Euclid — for we have everywhere set aside Campanus's sequence, as we explained at the beginning of Book 1 — we have taken care that a double number be placed in the margin opposite the propositions, the upper showing Theon's order and the lower Campanus's sequence. And if only a single number is found in the margin, you should understand that there is then no discrepancy between Theon and Campanus as far as the numbering of the propositions is concerned.

THEOREM 1. PROPOSITION 1.

[Margin: j.]

Two unequal magnitudes being set out: if from the greater more than its half is taken away, and from the remainder again more than its half, and this is done continually, there will at length be left a certain magnitude that will be smaller than the assigned lesser magnitude.

Let two unequal magnitudes AB and C be set out, of which AB is the greater. I say that if from AB more than its half is taken away, and from the remainder again more than its half, and this is done continually, there will at length be left a certain magnitude smaller than C.

For multiply C as many times as needed, until the resulting magnitude DE is greater than AB — so that DE is the multiple of C next greater than AB. Divide DE into the parts DF, FG, GE, each equal to C. Then from AB take away more than its half, namely AH, and from the remainder HB more than its half, namely HI; and

let this be done continually, until the parts of AB are equal in number to the parts of DE. Let the parts AH, HI, IB, then, be as many as DF, FG, GE.

Now since DE is greater than AB, while from DE the part DF taken away is less than half — or exactly half, if DE is double C — whereas from AB the part AH taken away is more than half, the remainder FE will be greater than the remainder HB. (For since DE is greater than AB, if half were taken from DE and likewise half from AB, the remainder of DE would still be greater than the remainder of AB. Therefore, if from DE less than half is taken and from AB more than half, the remainder of DE will be greater than the remainder of AB.) Again, since FE is greater than HB, and from FE the half FG is taken — or at most less than half, if FE is more than double C — while from HB more than half, namely HI, is taken, the remainder GE will in the same way be greater than the remainder IB. Proceeding thus, we shall at length show that the last part of DE, here GE, is greater than the last part of AB, here IB. And since GE, the last part of DE, is equal to C, C too will be greater than IB, the last part of AB. And so IB is left, a magnitude smaller than C. Which was to be demonstrated.

Diagram. The principal figure for Proposition 1: three vertical straight segments drawn side by side.

- Left segment AB — labelled top to bottom B, I, H, A; the greater magnitude, divided at H and I into the parts AH, HI, IB.
- Middle segment C — a short vertical segment (the lesser magnitude C).
- Right segment DE — labelled top to bottom E, G, F, D; the multiple of C, divided at F and G into the parts DF, FG, GE (each equal to C).

The same will be demonstrated if from AB the half AH is taken, and from the remainder HB again the half HI, and so on. For by the same reasoning the remainder FE will be greater than the remainder HB, and likewise the remainder GE greater than the remainder IB — since from the greater DE the part DF taken is less than half, or at most half, while from the lesser AB the half AH is taken, and so on.

Otherwise. With the construction made as before, take KL to be such a multiple of IB as DE is of C. Divide KL, then, into the parts KM, MN, NL, each equal to IB; there will be as many parts in KL as in DE. Now since AH is greater than HB — or at least equal to it, if a half was taken from AB — and HB is greater than IB, AH too will be greater than IB, that is, greater than KM. Again, since HI is greater than IB, or at least equal to it, and IB is equal to MN, HI too will be greater than MN, or equal to it; and thus the whole AI is greater than the whole KN.

Diagram. The figure for the "same"/"otherwise" demonstration of Proposition 1: again three vertical segments.

- Left segment AB — labelled top to bottom B, I, H, A, divided at H and I (parts AH, HI, IB).
- Middle segment C — a short vertical segment.
- Right segment DE — labelled top to bottom E, G, F, D, divided at F and G (parts DF, FG, GE).

than the whole KN. Adding, then, the equals IB and NL, the whole AB will be greater than the whole KL. But DE is greater still than AB; therefore DE is far greater than KL. Hence, since as DE is to C, so is KL to IB (for KL was taken to be as great a multiple of IB as DE is of C), [Margin: a — 14. quint. (Elements V.14)] C too will be greater than IB. And so IB is left, smaller than C. Which was to be demonstrated.

Diagram. The figure for the "otherwise" demonstration of Proposition 1, now including the auxiliary segment KL. Four vertical straight segments are drawn side by side.

- Segment AB — labelled top to bottom B, I, H, A; divided at H and I into AH, HI, IB.
- Segment KL — labelled top to bottom L, N, M, K; divided at M and N into the parts KM, MN, NL (each equal to IB).
- Segment DE — labelled top to bottom E, G, F, D; divided at F and G into DF, FG, GE.
- Segment C — a short vertical segment.

SCHOLIUM.

It is clearer than daylight, from the demonstration of this theorem, that two unequal quantities set out must be such that the lesser, when multiplied, can at length surpass the greater. This we pointed out at Proposition 16 of Book 3, when we were treating the angle of contact against Jacques Peletier [Iacobum Peletarium].

THEOREM 2. PROPOSITION 2.

[Margin: ij.]

If, two unequal magnitudes being set out, the lesser is continually subtracted from the greater by a certain alternating subtraction, and the

remainder never measures the one preceding it: then those magnitudes will be incommensurable.

Two unequal magnitudes AB, CD being set out, of which AB is the lesser: let AB be subtracted from the greater CD, and the remainder of this from AB, and so on in turn — by a certain alternating subtraction let the lesser always be taken from the greater — and let the remainder never measure the preceding magnitude. I say that the magnitudes AB, CD are incommensurable.

For if they are not incommensurable, some common measure will measure them. Let the magnitude E measure them, if it can — E being either equal to AB or smaller. Now let AB, subtracted from CD as often as possible, leave FD smaller than itself, so that AB measures CF. Again let FD, subtracted from AB, leave GB smaller than itself, so that FD measures AG; and let this be done continually. [Margin: a — 1. dec. (Elements X.1)] There will therefore at length be left, from CD or AB, some magnitude smaller than E. (For since AB, taken from CD, leaves FD smaller than itself, the part CF taken away is greater than half of CD; otherwise, if it were the half, or less than the half, AB could still be subtracted from CD. In the same way AG, taken from AB, is greater than half of AB; and since more than the half is always taken away, [Margin: b — 1. dec. (Elements X.1)] there will at length be left some magnitude smaller than E.) Let GB, now left, be smaller than E.

Since therefore E measures AB, and AB measures CF, [Margin: c — 2. pron. (Axiom II)] E will also measure CF. But E measures the whole CD as well. [Margin: d — 3. pron. (Axiom III)] Therefore E will also measure the remainder FD. But FD measures AG; [Margin: e — 2. pron. (Axiom II)] hence E will also measure AG. But E measures the whole AB as well. [Margin: f — 3. pron. (Axiom III)] Therefore E will also measure the remainder GB — a greater measuring a lesser. Which is absurd. Therefore no magnitude will measure the magnitudes AB, CD. Hence they are incommensurable. If, then, two unequal magnitudes being set out, [the lesser is continually subtracted from the greater, and the remainder never measures the preceding one, they are incommensurable,] and so forth. Which was to be shown.

Diagram. The figure for Proposition 2: three vertical segments.

- Segment AB — labelled top to bottom B, G, A (the lesser magnitude), with the division point G, giving the parts AG and GB.
- Segment CD — labelled top to bottom D, F, C (the greater magnitude), with the division point F, giving the parts CF and FD.
- Segment E — a medium vertical segment (the supposed common measure).

SCHOLIUM.

We shall convert this theorem in the following way.

If, two incommensurable magnitudes being set out, the lesser is always subtracted from the greater by a certain alternating subtraction: the remainder will never measure the preceding one.

Let AB, CD be incommensurable magnitudes, and let the lesser AB be subtracted from CD, the remainder being ED; likewise let ED be taken from AB, and let FB be left, and so on. I say that in this alternating subtraction the remainder never measures the preceding magnitude. For, if it be possible, let FB measure the preceding magnitude ED. Since, then, FB measures ED, and ED measures AF, [Margin: g — 2. pron. (Axiom II)] FB will also measure AF; and it measures itself as well. [Margin: h — 1. pron. (Axiom I)] Therefore FB will measure the whole AB too. But the whole AB also measures CE. [Margin: i — 2. pron. (Axiom II)] Therefore FB will measure CE as well. But FB is assumed to measure ED too; [Margin: k — 1. pron. (Axiom I)] therefore FB will also measure the whole CD. Yet it has been shown that FB measures AB as well. Hence FB measures both AB and CD — which is absurd, for AB, CD are assumed incommensurable. Therefore no remainder magnitude ever measures the preceding magnitude. Which is what was proposed.

We shall demonstrate this too in like manner.

If, two commensurable magnitudes being set out, the lesser is always subtracted from the greater by a certain alternating subtraction: some remainder will measure the preceding one.

For if no remainder ever measured the preceding one, the given magnitudes would be incommensurable, as Euclid demonstrated in this theorem. But that is absurd, for they are assumed to be commensurable.

Diagram. The figure for the Scholium of Proposition 2 (the converse): two vertical segments.

- Segment AB — labelled top to bottom B, F, A, with the division point F (parts AF and FB).
- Segment CD — labelled top to bottom D, E, C, with the division point E (parts CE and ED).

(Continuation of the Scholium to Proposition 2 — Clavius's converse test for commensurability.)

So from all this we shall easily recognize whether any two given magnitudes are commensurable or not. For suppose the smaller is always subtracted from the greater in a kind of alternating subtraction: if at some point a remainder measures the term before it, the given magnitudes will be commensurable, since that same remainder then measures both of the given magnitudes — as is clear from the demonstration of the first theorem of this scholium. For from the fact that the remaining magnitude FB was said to measure the preceding term ED, it was shown that this same remainder FB measures both magnitudes AB and CD. But if the remainder never measures the term before it, the given magnitudes will be incommensurable, as Euclid has demonstrated here.

PROBL. 1. PROPOS. 3.

Given two commensurable magnitudes, to find their greatest common measure.

Let AB and CD be the two given commensurable magnitudes, whose greatest common measure we are required to find. Since AB and CD are commensurable, it comes about that if the smaller, AB, subtracted from the greater, CD, as many times as possible, leaves ED; and ED, subtracted from AB as many times as possible, leaves FB; and this proceeds continually by a kind of alternating subtraction, then at last some remainder measures the term before it, by the second theorem of the preceding scholium. Suppose that FB, the remainder, now measures the preceding term ED. I say that FB is the greatest common measure of the magnitudes AB and CD.

That it measures both, we shall show as follows. Since FB measures ED, and ED measures AF, FB will also measure AF itself [Margin: a — 2.pron. (i.e. axiom 2 of Book X)]. But FB measures itself as well. Therefore FB [text prints *EB*; recte FB] will measure the whole of AB [Margin: b — 1.pron.]; and thus also CE, which AB measures [Margin: c — 2.pron.]. Since therefore it measures ED as well, FB will also measure the whole of CD [Margin: d — 1.pron.]; therefore FB measures both AB and CD. So FB is the common measure of both AB and CD.

That FB is their *greatest* common measure, we shall prove thus. If it is not the greatest, there will be some other common measure of them greater than FB. Let G, then, if it be possible, be their common measure greater than FB. Now since G measures both AB and CD, and AB measures CE, G will also measure CE [Margin: e — 2.pron.]. But it also measures the whole of CD; therefore G will also measure the remainder ED [Margin: f — 3.pron.]. But ED measures AF; therefore G too will measure AF [Margin: g — 2.pron.]. But this same G measures the remainder FB —

a greater measuring a smaller [Margin: h — 3.pron.]. This is absurd. Therefore no magnitude greater than FB is a common measure of AB and CD. So FB is their greatest common measure.

Diagram. Two tall vertical line-segments set side by side, with a short segment between them at the foot.

- Left segment AB: A (bottom endpoint), B (top endpoint), with F marked between them (dividing it into the lower part AF and the upper part FB); interior tick-marks show the alternating subtraction.
- Right segment CD: C (bottom endpoint), D (top endpoint), with E marked between them (dividing it into the lower part CE and the upper part ED).
- G: a short vertical segment at the foot, between A and C — the assumed common measure greater than FB used in the reductio.

But if the smaller magnitude AB measures the greater CD, so that when subtracted from CD it leaves nothing, then AB itself will be the greatest common measure of both, since it measures itself as well. Therefore, given two commensurable magnitudes, and so on. Which was to be done.

Diagram. Two vertical line-segments side by side, the short one measuring the long one exactly.

- Left segment AB (short): A (bottom endpoint), B (top endpoint).
- Right segment CD (long): C (bottom endpoint), D (top endpoint); interior tick-marks show AB laid off along CD a whole number of times.

COROLLARIVM.

From this it is clear that a magnitude measuring two magnitudes also measures their greatest common measure.

This is drawn from that part of the demonstration where FB was shown to be the greatest common measure of AB and CD. For it was there demonstrated that the magnitude G, if it measures the magnitudes AB and CD, also measures the greatest measure FB. And the reasoning is the same for the rest.

SCHOLIVM.

From what has been said, it will not be difficult to determine whether any number of given magnitudes are commensurable or not. Let there be three magnitudes A, B, C. First I test, by the method we taught at proposition 2 of this book, whether the two A and B are commensurable or not. If they are

incommensurable, it is plain that all three A, B, C are incommensurable, since they can have no common measure, on account of the incommensurable magnitudes A and B.

But if A and B are commensurable, and their greatest common measure D has been found, then if D also measures the magnitude C, it is clear that the three magnitudes A, B, C are commensurable, since they have D as a common measure.

But if D, the greatest measure of the magnitudes A and B, does not measure C, then C and D will be either commensurable or not. If they are incommensurable, then all three A, B, C will likewise be incommensurable. For if they were supposed commensurable, their greatest common measure would measure D, the greatest measure of magnitudes A and B, by the corollary of this proposition. Since therefore that same measure would also measure C, C and D would not be incommensurable — which contradicts the hypothesis.

Diagram. A column of illustrative horizontal line-segments (with interior tick-division marks), each labelled at its left end with a capital letter, accompanying the scholium: an upper group illustrating the three magnitudes and lower groups illustrating three and four magnitudes with their common measures.

- Segments labelled (top to bottom, left ends) A [?], B, C, and in the lower groups A, B, C, D — the rotated single-letter capitals are at the orientation/resolution floor and several cannot be resolved with certainty.

But if C and D are commensurable, then the three magnitudes A, B, C will also be commensurable [Margin: i — 3.decimi (Elements X.3)]. For, E having been found as the greatest measure of C and D, since E measures D, and D measures A and B, E will also measure A and B [Margin: k — 2.pron.]. Therefore, since the same E also measures C, E will measure the three magnitudes A, B, C; and for that reason they are commensurable. Which was proposed.

In the same way we shall investigate whether more than three given magnitudes are commensurable or not. For if four are given, we shall first test the matter on three; if five, on four; and so on. The rest we shall carry through as was said of three magnitudes.

Diagram. Four horizontal line-segments with interior tick-division marks, illustrating the three magnitudes A, B, C together with their common measure.

- Segments labelled at their left ends A, B, C, and a short segment (the common measure) whose rotated label reads as H [?] — reading uncertain.

PROBL. 2. PROPOS. 4.

[Margin: iv.]

Given three commensurable magnitudes, to find their greatest common measure.

Let A, B, C be the three given commensurable magnitudes, whose greatest measure we must find. Let D be found, the greatest measure of A and B [Margin: a — 3.decimi (X.3)]. If then D also measures C, it is evident that D is the greatest measure of all three A, B, C. For if a magnitude greater than D were said to measure the magnitudes A, B, C, that same magnitude would — by the corollary of proposition 3 of this book — measure the greatest measure of A and B, namely D itself: a greater magnitude measuring a smaller, which cannot happen. But if D does not measure C, then at least D and C will be commensurable. For since A, B, C are commensurable, any common measure of them will measure D, the greatest measure of A and B, by the corollary of the preceding proposition. Since therefore that same measure also measures C, D and C will be commensurable. Let E, then, be found, their greatest measure [Margin: b — 3.decimi (X.3)]. I say that E is the greatest measure of the given magnitudes A, B, C.

That it is their common measure will become plain thus. Since E measures D and C, and D measures A and B, E will also measure A and B [Margin: c — 2.pron.]. But it measures C as well; therefore E is the common measure of A, B, C, as we asserted.

That E is their greatest measure can be confirmed in this way. If it is not the greatest, let F, if it be possible, be a common measure of them greater than E. Since F measures A and B, it will also measure their greatest measure D, by the corollary of the preceding proposition. But it measures C too. Therefore F, measuring D and C, will also measure their greatest measure E, by the same corollary — a greater magnitude measuring a smaller. This is absurd. Therefore no magnitude greater than E measures A, B, C; and for that reason E is their greatest common measure. Wherefore, given three commensurable magnitudes, and so on. Which was to be done.

Diagram. Vertical line-segments illustrating the construction of Proposition 4.

- Segments A, B, C: the three given commensurable magnitudes (labelled A, B, C at the foot).
- D: the greatest measure of A and B (labelled to the right, upper).

- E: the greatest measure of D and C — the greatest common measure of all three (labelled to the right, upper); interior tick-marks show how D and E divide the segments.

COROLLARIVM.

It is also plainly gathered from this that a magnitude measuring three magnitudes also measures their greatest common measure.

This is inferred from the last part of the demonstration. For it was there shown that the magnitude F, if it measures A, B, C, also measures E, their greatest common measure. And the reasoning is the same for the rest.

In like manner, given more than three commensurable magnitudes, we shall find their greatest common measure; and this same corollary will hold. For if the given magnitudes are four, one must first find the greatest common measure of three of them; if five, one must take the greatest measure of four magnitudes; and so on. All the rest is to be carried through as was said of three magnitudes.

LEMMA.

If there are any number of magnitudes, and just as many numbers taken two by two in the same ratio as the corresponding pairs of magnitudes, then *ex aequali* [*ex æquo*] the magnitudes and the numbers will also be in the same ratio.

Let there be any number of magnitudes A, B, C, D, in the same ratios as just as many numbers E, F, G, H — namely, as A is to B, so E to F; and as B to C, so F to G; and as C to D, so G to H. I say that *ex aequali*, as A is to D, so E is to H. For, from what we demonstrated on definition 5 of book 6, the ratio of A to D is compounded of the ratios A to B, B to C, and C to D, just as the ratio of E to H is compounded of the ratios E to F, F to G, G to H. Since, then, the ratios that compound the ratio A to D are set equal to the ratios that compound the ratio E to H, it is clear that the compounded ratios too — namely A to D, and E to H — are equal; that is, as A is to D, so E is to H. Which was proposed.

Diagram. Four horizontal line-segments with interior tick-division marks, representing the magnitudes, each paired with its number in the right margin.

- A (divided into 3 parts) — paired with number E, 3.
- B (divided into 4 parts) — paired with number F, 4.
- C (undivided, short) — paired with number G, 1.
- D (divided into 2 parts) — paired with number H, 2.

The same follows if the proportion of magnitudes and numbers is perturbed [ex aequali in perturbed proportion], as appears in this example, in which as A is to B, so G to H; and as B to C, so F to G; and as C to D, so E to F. For the demonstration is entirely the same.

Diagram. Four vertical line-segments with interior tick-division marks, representing the magnitudes A, B, C, D, each paired with its number in the left margin — the perturbed-proportion example.

- Segments labelled at the foot A, B, C, D.
- Marginal numbers: E, 3; F, 12; G, 4; H, 6.

SCHOLIVM.

Since we shall need to use the preceding lemma both in the proposition that follows and in many others, it seemed good to demonstrate it here briefly, for it does not readily appear to follow from what has been demonstrated. Magnitude and number constitute different kinds of quantity; but the proportion *ex aequali*, in the preceding books, was shown only for quantities of the same kind — for numbers in book 7, and for magnitudes in book 5. Yet the demonstration made in the fifth book could be transferred to this lemma as well, since all the demonstrations of that book apply to numbers too. Or, at all events, the demonstration made in book 7 will fit this same lemma, since the magnitudes A, B, C, D, which have the same ratios as the numbers E, F, G, H, take on the character of numbers.

THEOR. 3. PROPOS. 5.

[Margin: v.]

Commensurable magnitudes have to one another the ratio which a number has to a number.

Let A, B be commensurable magnitudes. I say that they have to one another the ratio which some number has to another number. Let C be found, their greatest measure [Margin: a — 3.decimi (X.3)]; and as often as C, repeated, measures A, so often let a unit, repeated, measure the number D; and as often as the same C, repeated, measures B, so often let a unit, repeated, measure the number E. Since, then, the magnitude C measures the magnitude A, and the unit measures the number D, an equal number of times, the magnitude A will contain the magnitude C as many times as the number D contains the unit. Therefore, as A is to C, so is the number D to the unit. And likewise, as C is to B, so is the unit to the

number E; because C measures B, and the unit measures the number E, an equal number of times. Therefore, by the preceding lemma, *ex aequali*, as the magnitude A is to the magnitude B, so is the number D to the number E. Therefore commensurable magnitudes have to one another the ratio, and so on. Which was to be demonstrated.

Diagram. Three vertical line-segments with interior tick-division marks, illustrating Proposition 5.

- A (measured into 3 parts by C) — paired with number D, 3.
- C: their greatest common measure — paired with the label Vni. tas (the unit).
- B (measured into 2 parts by C) — paired with number E, 2.
- Segments labelled at the foot A, C, B.

SCHOLIUM.

Since Euclid, for the demonstration of this theorem, assumes the greatest common measure of the given commensurable magnitudes — such as C was, of A and B — it is clear that the lines must be commensurable in length, and for that reason commensurable in power [square] as well, so that they may have to one another the ratio of a number to a number. For these alone admit a common measure, and so it is in these that the demonstration has place.

But if the lines are commensurable only in power, their squares will indeed have to one another the ratio of a number to a number — because they are commensurable, and therefore have a common measure, and the demonstration of this theorem fits them. The lines themselves, however, by no means do so; for since they are incommensurable in length, they lack a common measure, and for that reason the demonstration of this theorem can in no way fit them.

Further, from the demonstration of this same theorem it is plainly established that the ratio of commensurable magnitudes is that which the numbers have by which their greatest common measure measures them. For it was shown that the magnitudes A and B have the ratio which the numbers D and E have — the numbers, that is, by which their greatest common measure C measures them.

Hence, if for two given commensurable magnitudes A and B one wishes to find in what ratio they stand as numbers, one must take two numbers D and E which the unit measures in just the way that C, the greatest common measure of the commensurable magnitudes A and B, measures those magnitudes. For, as was

demonstrated, the magnitudes A and B have the ratio which the numbers D and E have.

But if, instead of the greatest measure C, we take any other common measure of them, we shall nonetheless demonstrate this theorem by the same argument. For although the numbers D and E come out greater in this latter demonstration than in the former, they still have the same ratio to one another, as appears from the adjoining figure. But since, in the former demonstration, the numbers found are the least of all having the same ratio, it was perhaps for this reason that Euclid assumed in his demonstration the greatest common measure, and not just any measure — though this is not necessary.

Diagram. Three vertical line-segments with interior tick-division marks, illustrating the scholium's alternative with a smaller common measure.

- A (measured into 6 parts) — paired with number D, 6.
- C: the (non-greatest) common measure taken — paired with the label Vnitas (the unit).
- B (measured into 4 parts) — paired with number E, 4.
- Segments labelled at the foot A, C, B.

THEOR. 4. PROPOS. 6.

[Margin: vj.]

If two magnitudes have to one another the ratio which a number has to a number, the magnitudes will be commensurable.

Let two magnitudes A, B have the ratio which the numbers C, D have. I say that the magnitudes A, B are commensurable. For, as often as the unit is contained in the number C, let the magnitude A be understood as divided into that many equal parts, of which parts let the magnitude E be equal to one. Then, as often as the unit, repeated, measures the number D, [the demonstration continues]

PROP. 6 (demonstration, continued) [Margin: vj.]

If two magnitudes have to one another the ratio which a number has to a number, the magnitudes will be commensurable.

(Continuing the demonstration begun in the previous pages: A and B have the ratio of the numbers C, D; A has been divided into as many equal parts as there are units in C, of which E is one.) Then let the magnitude E, repeated as many times as the unit is contained in D, measure off some other magnitude F. Since,

then, the magnitude E is contained in A just as many times as the unit is contained in C, A will contain E exactly as many times as the number C contains the unit. Therefore A is to E as C is to the unit. And likewise, as E is to F, so is the unit to D — because E measures F, and the unit measures D, the same number of times. So, by the lemma to proposition 4 of this book, *ex aequali*, A will be to F as C is to D. But it was also given that as C is to D, so is A to B. Therefore A is to B as A is to F [Margin: a — 9.quin (Elem. V.9)]; and consequently the magnitudes B and F are equal to one another. Hence, since E measures F, the same E will also measure B; but it measured A as well. Therefore the magnitude E measures both A and B [Margin: b — 1.def (Elem. X, def. 1)], and accordingly A and B are magnitudes commensurable with one another. If, then, two magnitudes have to one another the ratio which a number has to a number, and so on. Which was to be demonstrated.

ALITER (an alternative proof). Let the magnitude A be conceived as divided into as many equal parts as there are units in C, one of which parts is equal to the magnitude E. Since, then, E is to A as the unit is to C — because E measures A, and the unit measures C [recte C; the text prints "D"], the same number of times — and since it is laid down that A is to B as C is to D, then by the same lemma above, *ex aequali*, E will be to B as the unit is to D. But the unit measures the number D. Therefore the magnitude E also measures the magnitude B [recte B; the text prints "E"]; and E measures A as well. Therefore A and B, having the same common measure E, are commensurable [Margin: c — 1.def (Elem. X, def. 1)]. Which is what was proposed.

Diagram. Vertical line-segments illustrating the magnitudes and numbers of Prop. 6. Reading the bottom labels left to right, three segments are lettered B, E, F (a fourth segment, the whole magnitude A on the far left, is largely cut off at the margin [?]). To the right, the corresponding quantities are shown: the number C = 5 (upper), the unit (Vni.tas = unitas, middle), and the number D = 3 (lower).

- B (bottom): magnitude B
- E (bottom): the part E of A
- F (bottom): magnitude F
- C, 5 (right): the number C = 5
- Vni.tas (right): the unit
- D, 3 (right): the number D = 3

Diagram. The line-figure for the alternative proof of Prop. 6. Bottom labels, left to right: E, A, B. To the right, the quantities: the unit (Vni-tas), the number $C = 5$, and the number $D = 3$.

- E (bottom): the part E of A
- A (bottom): magnitude A
- B (bottom): magnitude B
- Vni-tas (right): the unit
- C, 5 (right): the number $C = 5$
- D, 3 (right): the number $D = 3$

COROLLARIVM

From the earlier demonstration of the theorem a method is now open to us for finding a straight line to which any other given straight line has the ratio of a number to a number. For (repeating the earlier figure of this proposition) if a line is to be found to which the given line A has the ratio which the number C has to the number D, then A must be divided into as many equal parts as there are units in C, and another line F must be taken consisting of as many of those same parts as there are units in D. If this is done, A will be to F as C is to D, as has been demonstrated.

From this it further appears by what method one can find a straight line whose square has to the square of another given straight line the ratio of a number to a number. For if a line is to be found whose square has to the square of the given line A the ratio which the number C has to the number D, then first the line F must be found — by the method just described — to which A has the ratio of C to D. Next, the mean proportional G is to be taken between A and F [Margin: d — 13.sex (Elem. VI.13)]. For then the square on A will be to the square on G as the number C is to the number D. Since the three straight lines A, G, F are continually proportional, then by the corollary to proposition 20 of book 6, the square on A will be to the square on G as A is to F — and hence as the number C is to the number D (since A is to F as C is to D) — because all squares are similar figures similarly described.

Diagram. The corollary's line-figure (the earlier figure repeated). Bottom labels, left to right: A, G, F, where G is the mean proportional between A and F. Beside them, the numbers $C = 5$ and $D = 3$.

- A (bottom): the given line A
- G (bottom): the mean proportional between A and F

- F (bottom): the line F, to which A has the ratio $C : D$
- C, 5 (right): the number $C = 5$
- D, 3 (right): the number $D = 3$

SCHOLIVM

In this theorem too it is evident that lines having the ratio of a number to a number are commensurable both in length and in power (square), and not merely in power — since, as is clear from the demonstration, they have a common measure, just as the magnitudes A and B were shown to have the common measure E.

THEOR. 5. PROPOS. 7. [Margin: vij.]

Incommensurable magnitudes do not have to one another the ratio which a number has to a number.

Let A and B be incommensurable magnitudes. I say that they do not have the ratio which a number has to a number. For if A and B are said to have the ratio of a number to a number, they will be commensurable [Margin: a — 6.deci (Elem. X.6)]. But this is absurd, since they are assumed to be incommensurable. Therefore A and B do not have the ratio which a number has to a number. Hence incommensurable magnitudes, and so on. Which was to be shown.

Diagram. Two vertical line-segments labelled A and B (bottom), the two incommensurable magnitudes of Prop. 7.

- A (bottom): magnitude A
- B (bottom): magnitude B

SCHOLIVM

In whatever way lines are incommensurable — whether in length and in power, or in length only — we shall always conclude that they do not have the ratio of a number to a number, as the theorem requires. For otherwise, as has been demonstrated, they would be commensurable in length. But that is not assumed.

THEOR. 6. PROPOS. 8. [Margin: viij.]

If two magnitudes do not have to one another the ratio which a number has to a number, the magnitudes will be incommensurable.

Let the magnitudes A and B not have to one another the ratio which a number has to a number. I say that they are incommensurable. For if A and B are believed to be commensurable, their ratio will be that of a number to a number [Margin: a — 5.deci (Elem. X.5)]. But this is absurd, since they are assumed not to have the ratio of a number to a number. Therefore A and B are not commensurable. Accordingly, if two magnitudes do not have to one another the ratio of a number to a number, and so on. Which was to be shown.

Diagram. Two vertical line-segments labelled A and B (bottom), the two magnitudes of Prop. 8.

- A (bottom): magnitude A
- B (bottom): magnitude B

SCHOLIUM (of Prop. 8)

If lines do not have the ratio which a number has to a number, they will necessarily, by this theorem, be incommensurable in length; otherwise they would have the ratio of a number to a number, as we demonstrated at proposition 5 of this book — which is contrary to the hypothesis. It must not, however, be inferred from this theorem that lines which do not have the ratio of a number to a number are necessarily incommensurable in power, as is evident from the demonstration. For it does not follow, if they are commensurable in power only, that they have the ratio of a number to a number, as is assumed in the demonstration of the theorem; on the contrary, they could in no way have such a ratio, as we taught in the scholium to proposition 5 of this book. The only conclusion drawn from the demonstration of this theorem, therefore, is that lines not having the ratio of a number to a number are incommensurable in length.

LEMMA

If there are three quantities continually proportional, and three other quantities also continually proportional, and if the first of the one set is to its third as the first of the other set is to its third, then also the first of the one set will be to its second as the first of the other set is to its second.

Let there be quantities A, B, C continually proportional, and likewise D, E, F — whether the former are in the same kind as the latter or not — and let A be to C as D is to F. I say also that A is to B as D is to E. For since the ratio of A to C is the duplicate of the ratio of A to B, and the ratio of D to F is the duplicate of the ratio of D to E, and since the ratios A : C and D : F are laid down as equal, the ratios A : B and D : E will also be equal — inasmuch as their duplicate ratios are equal.

The same follows if there are more quantities than three: provided that, for four, we take the triplicate ratio in place of the duplicate for the demonstration; and for five, the quadruplicate; and so on.

Diagram. Three horizontal line-segments, one above another, illustrating the Lemma. Each is doubly labelled — by a letter of the first triple (A, B, C, set sideways at the left ends) and by a letter and value of the second triple (at the right ends): D = 49, E = 42, F = 36. The values 49 : 42 : 36 are continually proportional in the ratio 7 : 6.

- A / D, 49 (top line): first quantity; D = 49
- B / E, 42 (middle line): second quantity; E = 42
- C / F, 36 (bottom line): third quantity; F = 36

THEOR. 1. PROPOS. 9. [Margin: ix.]

Squares formed on straight lines commensurable in length have to one another the ratio which a square number has to a square number; and squares that have to one another the ratio which a square number has to a square number will also have sides commensurable in length. But squares formed on straight lines incommensurable in length do not have to one another the ratio which a square number has to a square number; and squares that do not have to one another the ratio which a square number has to a square number will not have sides commensurable in length either.

[Part 1.] Let AB, CD be first commensurable in length. I say that the square on AB has to the square on CD the ratio which a square number has to a square number. For since the straight lines AB, CD are commensurable in length, AB will be to CD as a number is to a number [Margin: a — 5.deci (Elem. X.5)]; let it be as the number E is to the number F, and let the squares of E and F themselves be G and H. Since, then, AB is to CD as the number E is to the number F, and since the square on AB has to the square on CD the duplicate ratio of the side AB to the side CD [Margin: b — 20.sex (Elem. VI.20)], and likewise the square number G has to the square number H the duplicate ratio of the side E to the side F [Margin: c — 11.oct (Elem. VIII.11)], the ratio of the square on AB to the square on CD will be the same as that of the square number G to the square number H — inasmuch as both these ratios are the duplicates of equal ratios. Which is what was proposed.

Diagram. Two squares side by side. The left square stands on the base A—B and is divided by a 2×2 grid into 4 cells (the square number G = 4, side E = 2); the right

square stands on the base C—D and is divided by a 3×3 grid into 9 cells (the square number H = 9, side F = 3). Below: the numbers E = 2, F = 3, G = 4, H = 9.

- A, B (base of left square): the line AB
- C, D (base of right square): the line CD
- E, 2 : side of the first square-number
- F, 3 : side of the second square-number
- G, 4 : the square number on E
- H, 9 : the square number on F

ALITER (an alternative proof). With the same construction laid down, let the rectangle BD be contained by the straight lines AB, CD; and let E and F, multiplying one another, produce I, which will be the mean proportional between the squares G and H — as is clear from the demonstration of proposition 11 of book 8 — and hence stands in the ratio of the side E to the side F, as we said in the scholium to that same proposition. Since, then, AB is to CD as E is to F, and since AB is to CD as the square on AB is to the rectangle BD (because of the common height AB, if CD is taken as the base of the rectangle) [Margin: d — 1.sexti (Elem. VI.1)], and likewise E is to F as G is to I, the square on AB will also be to the rectangle BD as the square number G is to the number I. Again, since AB is to CD as E is to F, and since AB is to CD as the rectangle BD is to the square on CD (because of the common height CD) [Margin: e — 1.sexti (Elem. VI.1)], if AB...

Diagram. The figure for the alternative proof: three rectilinear figures in continued proportion. The first is the square on AB (2×2 grid, 4 cells = G); the second is the rectangle BD contained by AB and CD (2×3 grid, 6 cells = the mean I); the third is the square on CD (3×3 grid, 9 cells = H). Their corner labels are set sideways in the print and are only partly legible.

- C, D : corners of the square on CD
- I (upper corner): the mean proportional, the rectangle BD [?]
- (two further sideways corner labels are not securely legible [?] [?])

LIBER X (continued)

[Part 2 — ALITER, continued.] ...if AB is taken as the base of the rectangle; and likewise E is to F as I is to H — the rectangle BD will also be to the square on CD as the number I is to the square number H. Therefore three magnitudes — the square on AB, the rectangle BD, and the square on CD — are in the same continued ratio in which the three numbers G, I, H stand. So, *ex aequali*, by the

lemma to proposition 4 of this book, the square on AB will be to the square on CD as the square number G is to the square number H. Which is what was proposed.

[Part 3, converse.] Secondly, let the square on AB be to the square on CD as the square number G is to the square number H. I say that the straight lines AB, CD are commensurable in length. For let the numbers E and F be the sides of the square numbers G and H, as in the earlier figure. Since, then, the square on AB is to the square on CD [recte CD; the text appears to read "BD"] as the square number G is to the square number H, and since the square on AB has to the square on CD the duplicate ratio of the side AB to the side CD [Margin: f — 20.sex (Elem. VI.20)], and likewise the square number G has to the square number H the duplicate ratio of the side E to the side F [Margin: g — 11.oct (Elem. VIII.11)], the ratio of the side AB to the side CD will be that of the side E to the side F — inasmuch as the duplicate ratios of these ratios are equal. Therefore, since the straight lines AB, CD have the ratio which the numbers E, F have, they will be commensurable in length. Which is what was proposed.

ALITER (of Part 3). Let the construction of the later figure be repeated. Since AB is to CD as the square on AB is to the rectangle BD [Margin: h — 6.dec (Elem. X.6)], and likewise AB is again to CD as the rectangle BD is to the square on CD, as we said above, the square on AB, the rectangle BD, and the square on CD will be continually proportional in the ratio of the line AB to the line CD. But the numbers G, I, H are also continually proportional in the ratio of the number E to the number F, as we showed above; and the square on AB is laid down to be to the square on CD as the square number G is to the square number H. Therefore, by the preceding lemma [Margin: i — 1.sextri (Elem. VI.1)], AB will be to CD as G is to I, that is, as E is to F; and therefore AB, CD, being straight lines having the ratio which the numbers E, F have, are commensurable in length [Margin: k — 6.dec (Elem. X.6)]. Which is what was proposed.

[Part 4.] Thirdly, let the straight lines A, B be incommensurable in length. I say that their squares do not have the ratio which a square number has to a square number. For if the square on A is said to have to the square on B the ratio which a square number has to a square number, then A, B will be commensurable in length, as has already been demonstrated. But that is absurd, since they are assumed incommensurable in length. Therefore the square on A does not have to the square on B the ratio which a square number has to a square number. Which is what was proposed.

[Part 5.] Fourthly and lastly, let the square on A not have to the square on B the ratio which a square number has to a square number. I say that they are

incommensurable in length. For if they are believed to be commensurable in length, their squares — as has been demonstrated — will have the ratio which a square number has to a square number. But that is absurd, since they are assumed not to have it. Therefore A and B are not commensurable in length. Which is what was proposed. Therefore squares formed on straight lines commensurable in length, and so on. Which was to be demonstrated.

Diagram. Two vertical line-segments labelled A and B (bottom), the two straight lines incommensurable in length treated in the third and fourth parts of the proposition.

- A (bottom): line A
- B (bottom): line B

COROLLARIVM

From these things it is evident that straight lines which are commensurable in length are altogether commensurable in power (square) as well; but those commensurable in power are not altogether commensurable in length too. And lines that are incommensurable in length are not altogether incommensurable in power; but those incommensurable in power are altogether incommensurable in length as well.

For since the squares of lines commensurable in length have the ratio which a square number has to a square number — as was demonstrated in this theorem — that is, simply the ratio of a number to a number, they will be commensurable [Margin: l — 6.dec (Elem. X.6)]; and therefore their sides too will be commensurable in power [Margin: m — 3.defin (Elem. X, def. 3)]. Hence lines commensurable in length are commensurable in power as well.

Next, since lines whose squares do not have the ratio which a square number has to a square number, but nevertheless the ratio simply of a number to a number, are indeed commensurable in power [Margin: n — 3.defi (Elem. X, def. 3)] — because their squares are commensurable [Margin: o — 6.dec (Elem. X.6)] — but by no means commensurable in length, as was shown in this theorem: it is clear that lines commensurable in power are not altogether commensurable in length. For only those lines commensurable in power whose squares have the ratio which a square number has to a square number are also commensurable in length, as is established from the second part of this theorem.

Again, since lines whose squares do not have the ratio which a square number has to a square number, but nevertheless the ratio of a number to a number, are

indeed incommensurable in length yet commensurable in power, as we have just said, it plainly follows that lines incommensurable in length are not altogether incommensurable in power. For only those lines incommensurable in length whose squares do not have the ratio of a number to a number are incommensurable in power as well [Margin: p — 4.defi (Elem. X, def. 4)], since their squares are incommensurable [Margin: q — 8.deci (Elem. X.8)].

Finally, that lines incommensurable in power are altogether incommensurable in length as well is evident. For if they were commensurable in length, they would be commensurable in power too, as is clear from the first part of the corollary. But that is absurd, since they are assumed incommensurable in power. For this reason lines incommensurable in power are altogether incommensurable in length as well.

SCHOLIVM

In order that the aim of the first two parts of this theorem may be grasped more clearly and completely, the following points are to be carefully considered. First, that straight lines commensurable in length — whose squares, by the first part of the theorem, have the ratio which a square number has to a square number — are not only those which can be expressed by numbers, if with... ..are compared with the proposed Rational line — such as those set out in the demonstration (for line AB is 2 and CD is 3) — but also those which can be expressed by no numbers at all, when compared with the proposed Rational line.

Then, conversely: squares that have to one another the ratio of a square number to a square number — whose lines, that is, sides, by the second part of the theorem, are commensurable in length — must be understood to include not only those that contain just as many square measures, equal to those into which the square of the Rational line is resolved, as there are units in the square numbers that have the same ratio to one another. Of this kind are the squares drawn in the demonstration (for the square on AB contains four square measures, and the square on CD nine — exactly as many units as there are in the square numbers G and H). They must also include those squares that embrace either fewer or more square measures than there are units in those square numbers, when they are compared with the square of the Rational line. For very often given lines are commensurable with one another in length, yet cannot be expressed in numbers, because they are incommensurable in length with the proposed Rational line. And therefore their squares do indeed have the ratio of a square number to a square number, as has been shown in this theorem, yet each contains either

fewer or more square measures than there are units in those square numbers. All this we shall make clear by the following demonstration.

[Margin: 26.oct. — Elements VIII.26] [Margin: 14.sec. — Elements II.14]

Let the Rational line AB be set out, expressed by the number 4; its square AC will contain 16 square measures. Let there also be numbers D and E, similar plane numbers but not squares, which nevertheless have [Margin: r — 26.oct., Elements VIII.26] — as is proved in the arithmetical books — the ratio that the square number F has to the square number G, namely 4 to 16. Next, take a rectangle HI made up of six square measures of the square AC — exactly as many units as are contained in the number D; and [Margin: s — 14.sec., Elements II.14] construct a square KL equal to this HI, whose side is KM. Finally, by what we showed in the corollary to Proposition 6 of this book (*Elements* X.6, Cor.), let a line NO be found such that KL, the square of the line KM, is to its square NP as the number D is to the number E, or as the square F is to the square G.

Since, then, as the square number F is to the square number G — or as the number D is to the number E, namely 6 to 24 — so is the square KL to the square NP, by construction; and since the square KL contains 6 square measures, of which the Rational square AC contains 16 (for the square KL was constructed equal to the rectangle HI, which is made up of 6 such square measures), the square NP will contain 24 of these same square measures. And therefore KM and NO, the sides of the squares KL and NP, will be $\sqrt{6}$ and $\sqrt{24}$, which cannot be expressed in numbers, since 6 and 24 are not square numbers. They will be incommensurable in length with the Rational line AB, but commensurable in length with one another — by this theorem — since their squares have the ratio that the square number F has to the square number G.

Diagram. A group of geometric figures illustrating the worked example.

- Rectangle **HI**: a tall narrow column (H at top-left, I at bottom-left) divided by cross-lines into six equal cells — the rectangle HI, "made up of six square measures" of the Rational square.
- Square **AC**: a square with A at bottom-left, B at bottom-right, C at top-right, divided into a 4×4 grid; the number 4 is marked along the base AB — the square of the Rational line AB (side 4, sixteen square measures).
- A block of numeral labels between the two upper figures: **D.6 E.24 / F.4 G.16 / Q.9 R.36** (the numbers D = 6, E = 24; F = 4, G = 16; Q = 9, R = 36).

- Small square **KL**: with K at bottom-left, L at top (side KM at the base, M at bottom-right), the numeral **6** inside and **R.6** ($= \sqrt{6}$) marked below the base — the square KL of 6 measures.
- Large square **NP**: with N at bottom-left, P at top-right, O at bottom-right, the numeral **24** inside and **R.24** ($= \sqrt{24}$) marked along the base NO — the square NP of 24 measures.

This can also be established as follows. Since the squares KL and NP have [Margin: t — 6.deci., Elements X.6] the ratio which is the duplicate of that of their sides KM and NO (by the corollary to Proposition 20 of Book VI, *Elements* VI.20, Cor.), and since the ratio of the squares is one-fourth (subquadruple), namely 1 to 4, the ratio of the sides will be one-half (subduple), namely 1 to 2 — for the former is the duplicate of the latter, as appears here: 1, 2, 4. Therefore the lines KM and NO are commensurable in length, since they have the ratio of a number to a number. So in this theorem we must include, among lines commensurable in length, also those that cannot be expressed in numbers when compared with the Rational line. But if these same lines KM and NO are considered simply and absolutely, without any regard to the Rational line AB, they can be expressed in numbers. For since they stand in a one-to-two (subduple) ratio, if KM is divided into two equal parts, NO will be divided into four parts of the same size; if KM into three, NO will be cut into six, and so on. But these parts are in no way equal to the parts of the Rational line AB; indeed they are altogether incommensurable in length with them, as we have said.

Again: since the squares KL and NP have the ratio that the square number F has to the square number G, they contain more square measures — equal to those into which AC, the square of the Rational line AB, is resolved — than there are units in the said square numbers F and G (for KL is equal to six such measures, and NP contains 24, whereas the square number F is made up of four units and G of sixteen). And if larger squares Q and R are taken in the same ratio, the squares KL and NP embrace fewer such measures than there are units in the square numbers Q and R, since one is made up of 9 units and the other of 36. It is therefore clear that in this theorem we must also include squares having the ratio of a square number to a square number which comprehend either fewer or more square measures than the units found in those square numbers, when they are compared with the square of the proposed Rational line. But if the same squares KL and NP are considered absolutely and simply, without any regard to the square AC described on the Rational line AB, they can be resolved into just as many square measures as there are units contained in the square numbers F, G and Q, R. For if the line KM is divided into two parts and NO into four, as was

said, the square KL will contain four square measures and the square NP sixteen — exactly as many units as are found in the square numbers F and G. Likewise, if the same lines are cut into three and six parts, their squares will have 9 and 36 square measures — exactly as many units as are comprehended in the square numbers Q and R, and so on. But measures of this kind are in no way equal to the square measures into which AC, the square of the Rational line AB, is resolved.

We shall say the same of all other squares and their sides whose areas are not expressed by square numbers, provided they have to one another the ratio of square numbers to square numbers — such as squares whose areas are 12 and 3, having the ratio that the square number 16 has to the square number 4, and so on.

Accordingly this theorem is to be understood of lines commensurable in length with one another, even though at times they are incommensurable with the Rational line — so that the sense is this: squares described on straight lines commensurable in length with one another — even though they are sometimes incommensurable in length with the proposed Rational line — have to one another the ratio of a square number to a square number, although the squares themselves, when compared with the square of the Rational line, very often cannot be expressed in square numbers at all. And squares having to one another the ratio of a square number to a square

number — whether or not these squares can be expressed in square numbers when compared with the square of the Rational line — will have sides commensurable in length with one another, even if those lines are incommensurable in length with the Rational line, and so on.

[Campanus] infers from this theorem that in square figures the diagonal is incommensurable in length with the side, in the following way. Since the square on the diagonal is double the square on the side, as we proved at Proposition 47 of Book I (*Elements* I.47); and since no double ratio can be the same as that of a square number to a square number — because between numbers in double ratio no mean proportional falls, as we showed in the scholium to Proposition 8 of Book VIII (*Elements* VIII.8, schol.) — the square on the diagonal and the square on the side will not have the ratio of a square number to a square number. Therefore, by the last part of this theorem, their sides — that is, the diagonal and the side in one and the same square — are incommensurable in length with one another. We too demonstrated this in the scholium to Proposition 7 of Book VIII (*Elements* VIII.7, schol.). [Euclid] will show it more clearly, however, in the last proposition of this book.

THEOR. 8. PROPOS. 10.

[Margin: x.] [Margin: xj.]

If four magnitudes be proportional, and the first be commensurable with the second, the third also will be commensurable with the fourth. And if the first be incommensurable with the second, the third also will be incommensurable with the fourth.

Let there be four proportional magnitudes A, B, C, D, and let A, the first, be commensurable with B, the second. I say that the third, C, is also commensurable with the fourth, D. For since A and B are commensurable with one another, [Margin: a — 5.deci., Elements X.5] A will have to B the ratio of a number to a number, namely that of E to F. But it is laid down that as A is to B, so is C to D. Therefore C also has to D the ratio that the number E has to the number F. [Margin: b — 6.dec., Elements X.6] Hence C and D are commensurable with one another.

But now let A be incommensurable with B. I say that C is also incommensurable with D. For since A and B are incommensurable, [Margin: c — 7.dec., Elements X.7] A will not have to B the ratio of a number to a number. But it is laid down that as A is to B, so is C to D. Therefore neither does C have to D the ratio of a number to a number. [Margin: d — 8.deci., Elements X.8] Hence C and D are incommensurable with one another. If, therefore, four magnitudes be proportional, and so on. Which was to be shown.

Diagram. Two short vertical line-segments at top, labelled **E.4** and **F.2** (the numbers $E = 4$ and $F = 2$), and below them four vertical line-segments of differing heights labelled, left to right, **A, B, C, D** — the four proportional magnitudes.

SCHOLIVM.

If the four given magnitudes are lines, and the first is commensurable in length with the second, the third also will be commensurable in length with the fourth, as appears from the demonstration of this theorem. For in the same way we shall show that the latter two have the ratio [recte: proportionem] of a number to a number. Therefore, as we said in the scholium to Proposition 5 of this book, they are commensurable in length.

But if the first is commensurable with the second in square only, the third also will be commensurable with the fourth in square only. For let the same figure be repeated. Since, then, A is commensurable with B, [Margin: e — 3.defin., Def. 3]

their squares will be commensurable, [Margin: f — 5.deci., Elements X.5] and therefore will have the ratio of a number to a number. [Margin: g — 22.sex., Elements VI.22] But as the square on A is to the square on B, so is the square on C to the square on D (because the four given lines A, B, C, D are proportional, and their squares are similar figures, similarly described). Therefore the squares on C and D also will have the ratio of a number to a number. [Margin: h — 6.deci., Elements X.6] Hence they will be commensurable; [Margin: i — 3.def., Def. 3] and consequently the lines C and D are commensurable in square. That they are commensurable in square only will be made clear thus. Since the lines A and B, being commensurable in square only, are incommensurable in length, their ratio will not be that of a number to a number, as we taught in the scholium to Proposition 7 of this book. And therefore neither will C and D have the ratio of a number to a number. So C and D are incommensurable in length, by the scholium to Proposition 8 of this book. But they are commensurable in square, as we showed. Therefore they are commensurable in square only. Which was proposed.

By the same reasoning, if the first is incommensurable with the second in length only, the third also will be incommensurable with the fourth in length only. For if A and B are incommensurable in length only, their squares will be commensurable [in square] only; and therefore they themselves will be commensurable in square only. Therefore, as we have just shown, the lines C and D also will be commensurable in square only; and for that reason they will be incommensurable in length only. Which was proposed.

Again, if of four magnitudes the first two are lines and the remaining two are surfaces or solids, it will nonetheless follow that, if the lines are commensurable or incommensurable in length, the remaining two magnitudes are commensurable or incommensurable as well. For if the lines are commensurable in length, their ratio will be that of a number to a number, from what we taught in the scholium to Proposition 5 of this book. Since, then, the remaining two magnitudes have the same ratio as the lines, their ratio also will be that of a number to a number; [Margin: k — 6.deci., Elements X.6] and so they will be commensurable. But if the lines are incommensurable in length — whether or not they are commensurable in square — their ratio will not be that of a number to a number, as is clear from the scholium to Proposition 7 of this book. Therefore neither will the ratio of the remaining two magnitudes, which have the same ratio as those lines, be that of a number to a number. [Margin: l — 8.dec., Elements X.8] Hence they will be incommensurable. Which was proposed.

In the same way, if the first two magnitudes are surfaces or solids and the latter two are lines, we shall prove that, whether the planes or solids are commensurable or incommensurable, the lines are commensurable or incommensurable in length. For if the planes or solids are commensurable, [Margin: m — 5.deci., Elements X.5] they themselves will have the ratio of a number to a number. Therefore the lines too, having the same ratio as they, will have the ratio of a number to a number; and consequently they will be commensurable in length, as we said in the scholium to Proposition 6 of this book. But if the planes or solids are incommensurable, they will not have the ratio of a number to a number. Therefore neither will the lines, having the same ratio as they, have the ratio of a number to a number. So they will be incommensurable in length, by what we taught in the scholium to Proposition 8 of this book. Which was proposed.

LEMMA.

To find two plane numbers that do not have the ratio of a square number to a square number.

Let two dissimilar plane numbers be found, by what we taught toward the end of Book VIII. For numbers of this kind will not have the ratio of a square number to a square number, as we demonstrated in the scholium to Proposition 26 of Book VIII (*Elements* VIII.26, schol.). Which was proposed.

But if we wish to find several numbers, no two of which have the ratio of a square number to a square number, we shall take as many prime numbers as we please — by what we set forth in the scholium to Proposition 20 of Book IX —

A, 3. B, 5. C, 7. D, 11. E, 13.

namely A, B, C, D, E. For no two of these accepted primes have to one another — by the scholium to Proposition 26 of Book VIII — the ratio of square numbers to square numbers, since they are not similar plane numbers, as we taught toward the end of Book VIII.

SCHOLIUM.

Now, the method of finding dissimilar plane numbers — that is, numbers which do not have the ratio of a square number to a square number — some have handed down incorrectly at this place, among them [Federico Commandino]. To show this, we must set out the method by which they try to find the said numbers. They proceed thus:

A, 2. C, 3. B, 6. D, 16. E, 12. F, 48.

Let four numbers A, B, C, D be set out such that A is not to C as B is to D; and let the number E be made from A and B [$E = A \times B$], and the number F from C and D [$F = C \times D$]. It is then clear that E and F are plane numbers, but dissimilar plane numbers, since their sides are not proportional. Which was required.

This is their method of finding dissimilar plane numbers. But such interpreters are mistaken, because very often the numbers found by their method are similar plane numbers. For the numbers found by their demonstration, 12 and 48, are similar plane numbers, since they have the ratio that the square numbers 4 and 16 have. And likewise it is agreed that the former number has sides 3 and 4, proportional to the sides 6 and 8 of the latter — even though the sides of the former that they assumed, 2 and 6, are not proportional to the sides 3 and 16 of the latter that they took. For it is enough, in order that two plane numbers be similar, that some two sides of the one be proportional to some two sides of the other; it is not required that any two sides whatever of the one be proportional to any two sides whatever of the other. On this matter we have written more at length at Definition 21 of Book VII and in the scholium to Proposition 23 of Book VIII.

PROBL. 3. PROPOS. 11.

[Margin: x.] [Margin: xj.]

Given a straight line, to find two straight lines incommensurable with it — the one in length only, the other in square as well.

Let A be the given line, for which a line incommensurable in length only is first to be found. By the preceding lemma, let two numbers B and C be found not having the ratio of a square number to a square number. Next, by the corollary to Proposition 6 of this book, let a line D be found such that the square on A is to the square on D as the number B is to the number C. I say that D is incommensurable with A in length only. That A and D are incommensurable in length will be proved thus. Since the square on A is to the square on D as the number B to the number C, and since the ratio of B to C is not that of a square number to a square number, neither will the square on A have to the square on D the ratio of a square number to a square number. [Margin: a — 9.dec., Elements X.9] Therefore the lines A and D are incommensurable in length. That they are incommensurable in length only is plain. For since the squares on A and D have the ratio that the number B has to the number C, [Margin: b — 6.dec., Elements

X.6] they will be commensurable. So the lines A and D are, by definition, commensurable in square. Hence they are incommensurable in length only.

Diagram. Three vertical line-segments of differing heights labelled, left to right, **A, E, D** — A being the given line, E the mean proportional, and D the line found. To the right stand the numeral labels **B, 10.** and **C, 6.** (the numbers $B = 10$ and $C = 6$, which do not have a square-to-square ratio).

Now, for the same given line A, a line incommensurable in both length and square is to be found. [Margin: c — 13.sex., Elements VI.13] Let a line E be found as the mean proportional between the lines A and D, which are incommensurable in length only. I say that E is incommensurable with A in both length and square. For since the square on A is to the square on E — by the corollary to Proposition 20 of Book VI (*Elements* VI.20, Cor.) — as A is to D, and since A is incommensurable in length with D, as has just been shown, [Margin: d — 10.dec., Elements X.10] the square on A also will be incommensurable with the square on E. Therefore the lines A and E are, by definition, incommensurable in square; and consequently, by the corollary to Proposition 9 of this book, they are altogether incommensurable in length as well. Therefore E is incommensurable with A in both length and square. And so, for the given straight line, we have found two straight lines, and so on. Which was to be demonstrated.

SCHOLIUM.

If, then, the given line A is set down as Rational, so that the measures of the others are taken from it, the line D also will be Rational, by Definition 6, since it is commensurable with A in square, even though it is incommensurable with it in length. But E is Irrational, by Definition 7, since it is incommensurable with the Rational line A in both length and square.

Moreover, from the demonstration of this theorem it is clearly established that a straight line which is the mean proportional between two straight lines...

Book X (continued)

Scholium to Proposition 11 (continued)

[a line which is the mean proportional between two lines] commensurable in power only — or, what amounts to the same thing, between two lines incommensurable in length only — is incommensurable with either of them in both length and power; and so it is called Irrational, if either of the two is taken to be Rational. For from the fact that the lines A and D are incommensurable in

length only — that is, commensurable in power only — we demonstrated that the line E, the mean proportional between them, is incommensurable with [A] in both length and power. And by the same argument we shall show that this same line is incommensurable with D itself in both length and power. For since the lines D, E, A are in continued proportion, by the corollary of Proposition 20 of Book VI it follows that as the square on D is to the square on E, so is the line D to the line A. But the line D is incommensurable in length with the line A. Therefore the square on D will also be incommensurable with the square on E. Hence the lines D and E, by definition [Margin: e. Elem. X.10 [?]], are incommensurable in power, and consequently also in length, by the corollary of Proposition 9 of this book.

Diagram. Three vertical straight-line segments of unequal length, drawn side by side. Read left to right at their feet:

- A: the longest (leftmost) segment
- E: the middle segment
- D: the shortest (rightmost) segment
- To the right of the figure, two numeric annotations: **B, 10** and **G, 6** (reference quantities used in the worked example).

In the common manuscripts this eleventh proposition is placed by Theon before the tenth, which precedes it; I judge that this was done through a copyists' error, since the second part of this [proposition] is demonstrated from the preceding tenth proposition, as is clear from what has been said.

THEOR. 9. PROPOS. 12.

[Margin: xij. / viij.]

Magnitudes commensurable with the same magnitude are also commensurable with one another.

Let each of the magnitudes A and B be commensurable with the magnitude C. I say that A and B are also commensurable with one another. For since A and C are commensurable, [Margin: a. Elem. X.5] A will have to C a ratio that a number has to a number: let it have the ratio that the number D has to the number E. Again, since C and B are commensurable, C will likewise have to B a ratio that a number has to a number: let it have the ratio that the number F has to the number G.

[Margin: b. Elem. VIII.4] Let three least numbers H, I, K be taken, in continued proportion in the ratios of D to E and of F to G; and let H be to I as D is to E — that is, as A is to C — and let I be to K as F is to G — that is, as C is to B. Since, then, A is

to C as H is to I, and C is to B as I is to K, it will be, from equality [ex æquo], that A is to B as H is to K, a number to a number. Therefore A and B, having the ratio of the numbers H and K, [Margin: c. Elem. X.6] are commensurable with one another. Therefore magnitudes commensurable with the same magnitude, etc. Which was to be demonstrated.

Diagram. Three vertical straight-line segments of unequal length, drawn side by side. Read left to right at their feet:

- A: the leftmost segment
- C: the middle segment
- B: the rightmost segment
- To the right, the numeric values of the worked example, in two columns: D, 10 · F, 2 · H, 5 and E, 8 · G, 3 · K, 6. (The number I is not assigned a value in the figure.)

SCHOLIVM.

But if the magnitudes A, B, C are lines, and A and B are commensurable in length with C, then A and B will also be commensurable in length with one another, as is plain from the demonstration of the theorem — for in the same way we shall show that the lines A and B have a ratio that the number H has to the number K; hence they will be commensurable in length, as we said at Proposition 6 [of this book]. But if A and B are commensurable in power with C — even though they are incommensurable in length with it — it will be shown, in the same way, that A and B are also commensurable in power with one another. For [Margin: d. Elem. X.5] the square on A will be to the square on C as one number to another — namely, as D to E — since the squares on A and C are, by definition, commensurable. In the same way the square on C will be to the square on B as one number to another — namely, as F to G. [Margin: e. Elem. VIII.4] Therefore, three least numbers H, I, K being taken in continued proportion in these same ratios of D to E and of F to G, it will again follow, from equality, that the square on A is to the square on B as the number H is to the number K. [Margin: f. Elem. X.6] Therefore the squares on A and B are commensurable, and hence the lines A and B are commensurable in power. It does not, however, follow from this that A and B are commensurable in power only. For there can be two lines commensurable in length with one another, even though each of them is commensurable in power only with some third line; such are two Rational lines commensurable in length with one another, but commensurable only in power with the assigned Rational line — lines that we shall in fact find later, in the second scholium to Proposition 19 of this book.

But we shall also demonstrate, in a certain way, the converse of this theorem, as follows.

If there be two commensurable magnitudes, and one of them be commensurable with some [third] magnitude, then the remaining one will also be commensurable with the same.

Diagram. Three horizontal dashed straight-line segments of unequal length, drawn one above another. Read top to bottom:

- A: the topmost (short) dashed segment
- C: the middle dashed segment
- B: the bottom (longest) dashed segment

Let A and B be commensurable, and let A be commensurable with C. I say that B too is commensurable with the same C. For since both B and C are commensurable with A, then B and C will also, by this theorem, be commensurable with one another. Which is what was proposed.

But if the magnitudes A, B, C are lines, and A, B are commensurable in length, while A is commensurable in length with C, then B, the remaining line, will also be commensurable in length with C. For since both B and C are commensurable in length with A, then B and C will likewise be commensurable in length with one another, as we showed. But if the lines A and B are commensurable in power only, and A is commensurable with C — whether in length and power, or in power only — we shall indeed conclude, by the same argument, that B, the remaining line, is commensurable in power with C, since on this reckoning each of B and C is commensurable in power with A by hypothesis. It will not, however, be permissible to conclude, when A is commensurable in length with C, that B, the remaining line, is commensurable in length with the same C, because B and C are not both commensurable in length with A — but rather C is so in length, while B is so in power only, as is established from the hypothesis.

THEOR. 10. PROPOS. 13.

[Margin: xij. [?] / ○ [?]]

If there be two magnitudes, and one of them be commensurable with some [magnitude] while the other is incommensurable [with it], the [two] magnitudes will be incommensurable [with one another].

Let there be two magnitudes A and B, of which A is commensurable with C while B is incommensurable with the same C. I say that A and B are incommensurable

with one another. For if B were said to be commensurable with A, then — since C is posited commensurable with the same A — [Margin: a. Elem. X.12] B and C would be commensurable with one another, which is absurd, since B is posited incommensurable with C. Therefore B is not commensurable with A. And so, if there be two magnitudes, and one of them, etc. Which was to be shown.

Diagram. Three vertical straight-line segments drawn side by side. Read left to right at their feet:

- A: the leftmost segment
- C: the middle segment
- B: the rightmost segment

SCHOLIVM.

If the magnitudes A, B, C are lines, and A is commensurable in length with C while B is incommensurable in length with the same C, then A and B will be incommensurable in length. For if they were commensurable in length, [Margin: b. Elem. X.12] we should also show that B and C are commensurable in length with one another (since, on this assumption, both B and C would be commensurable in length with A) — which is not posited. By the same reasoning, if A is commensurable in power with C — whether in power only, or also in length — while B is incommensurable in power with the same C, then A and B will be incommensurable in power. For if they were commensurable in power, B and C would likewise be commensurable in power (since, on this assumption, both B and C would be commensurable in power with A). Which is absurd; for B is posited incommensurable in power with C.

But since this proposition 13 is, in Theon, a lemma, it comes about that hereafter, in our edition, the numbering of Euclid's propositions differs from the numbering that Theon follows. For we have deliberately kept Theon's order and sequence at this place, because this theorem has now been received into the number of Euclid's propositions by the more recent and more skilled geometers.

THEOR. 11. PROPOS. 14.

[Margin: xiiij. / viij.]

If there be two commensurable magnitudes, and one of them be incommensurable with some magnitude, then the other will also be incommensurable with the same.

Let there be two commensurable magnitudes A and B, of which A is incommensurable with some other magnitude C. I say that B too is incommensurable with the same C. For if B were said to be commensurable with C — and therefore C with B — then, since A is posited commensurable with B, [Margin: a. Elem. X.12] A and C would be commensurable with one another. Which is absurd; for A is posited incommensurable with C. Therefore B is not commensurable with C. And so, if there be two commensurable magnitudes, etc. Which was to be demonstrated.

Diagram. Three vertical straight-line segments drawn side by side, A and B marked off with common divisions [tick-marks] to show their commensurability. Read left to right at their feet:

- A: the leftmost segment
- C: the middle segment
- B: the rightmost segment [printed as a rotated/malformed glyph resembling "3"; recte: B]

SCHOLIUM.

Here too, if the magnitudes A, B, C are lines, and A, B are commensurable in length, while A is incommensurable with C — whether in length only, or in both length and power — then B too will be incommensurable in length with C. For if C and B were commensurable in length,

[if C and B] were commensurable in length, [Margin: b. Elem. X.12] then A and C would likewise be commensurable in length (since, on this assumption, both A and C would be commensurable in length with B). Which is absurd; for A is posited incommensurable in length with C. But if A and B are commensurable in power only, and A is incommensurable in power with C, we shall conclude in the same way that B too is incommensurable in power with C. Otherwise, if B and C were commensurable in power, [Margin: c. Elem. X.12] then A and C would be commensurable in power (since, on this assumption, both A and C would be commensurable in power with B). Which is not posited.

Furthermore, from this theorem the interpreters of Euclid derive the following theorem, very useful for the things demonstrated in this book.

Magnitudes commensurable with incommensurable magnitudes will also be incommensurable with one another.

Let there be two incommensurable magnitudes A, B, with which C and D are commensurable — namely, C with A and D with B. I say that C and D are

incommensurable with one another. For since A and C are commensurable, [Margin: d. Elem. X.14] C, the remaining magnitude, will also be incommensurable with B. Again, since D and B are posited commensurable, and B has been shown incommensurable with C, [Margin: e. Elem. X.14] the remaining magnitude will also be incommensurable with the same C. Which is what was proposed.

But if the magnitudes A, B, C, D are lines, and A, B are incommensurable — whether in length only, or in both length and power — while C, D are commensurable in length with A, B respectively, then C and D will, by the same argument, be incommensurable in length. But if A and B are incommensurable in power, and C, D are commensurable in power only with them, we shall likewise show that C and D are incommensurable in power; as is evident.

Diagram. Four vertical straight-line segments of unequal length drawn side by side. Read left to right at their feet:

- C: the leftmost segment (commensurable with A)
- A: the second segment
- B: the third segment
- D: the rightmost segment (commensurable with B)

LEMMA.

Given two unequal straight lines, to find that by which the greater is more powerful than the lesser [i.e., the side of the square by which the square on the greater exceeds the square on the lesser].

Although we have shown before, at Proposition 47 of Book I, what this lemma proposes, nevertheless — because here it is demonstrated more briefly from what has been handed down in Books III and IV — we have judged it not useless to accomplish the same thing in another way at this place. Let there then be given two unequal straight lines AB and C, of which AB is the greater; and let it be required to find that by which AB is more powerful than C. Let AB be bisected at D, and from center D, with radius DA or DB, let the semicircle AEB be described; [Margin: f. Elem. IV.1] in it let the straight line AE be fitted equal to C, and let the straight line EB be joined. I say that AB is more powerful than C by the square on the line EB. [Margin: g. Elem. III.31] For since the angle E, in the semicircle, is a right angle, [Margin: h. Elem. I.47] the square on AB will be equal to the squares on AE and EB; and therefore AB will be more powerful than AE — that is, than C — by the square on the line EB. Which is what was proposed. In like manner:

Given two straight lines, whether equal or unequal, to find the straight line whose square equals [the sum of the squares on] them.

This too we have set forth at Proposition 47 of Book I. Let there then be, in the same figure, two given straight lines AE, EB, which, if they be joined at the right angle E, the straight line AB drawn [across] will be able to [subtend] them, [Margin: i. Elem. I.47] inasmuch as the square on AB is equal to the squares on AE and EB.

Diagram. A semicircle standing on the diameter AB, with a triangle inscribed and a separate line beneath.

- A: left end of the horizontal diameter
- D: midpoint of the diameter (center of the semicircle)
- B: right end of the diameter
- E: apex on the arc, where the chords AE and EB meet at a right angle [the printed apex glyph is faint/ambiguous — read as E to agree with the demonstration; possible]
- The chords AE (left) and EB (right) are drawn, forming triangle AEB; the angle at E is right
- C: a separate horizontal straight line drawn below the figure (the given line to which AE is fitted equal)

THEOR. 12. PROPOS. 15.

[Margin: xiv. / xij.]

If four straight lines be proportional, and the square on the first exceed the square on the second by the square on a straight line commensurable in length with the first, then the square on the third will exceed the square on the fourth by the square on a straight line commensurable in length with the third. But if the square on the first exceed the square on the second by the square on a straight line incommensurable in length with the first, then the square on the third will exceed the square on the fourth by the square on a straight line incommensurable in length with the third.

Let there be four proportional straight lines A, B, C, D, and let the first, A, be more powerful than the second, B, by the square on the line E; and let the third, C, be more powerful than the fourth, D, by the square on the line F. I say that, if E be commensurable in length with A, then F too is commensurable in length with C; but if E be incommensurable in length with A, then F too is incommensurable in

length with C. For since A is to B as C is to D, [Margin: a. Elem. VI.22] it will also be that as the square on A is to the square on B, so is the square on C to the square on D. But the square on A is equal to the squares on B and E, by hypothesis; and the square on C is equal to the squares on D and F. Therefore it will also be that as the squares on B and E are to the square on B, so are the squares on D and F to the square on D. And, by separation [dividendo], as the square on E is to the square on B...

Diagram. Six straight vertical line-segments of differing lengths, drawn side by side and lettered along the base. From left to right :

- A: a tall segment (the first of the four proportional lines)
- B: a shorter segment (the second proportional line)
- E: a short segment (the line by whose square A is more powerful than B)
- C: a tall segment (the third proportional line)
- D: a short segment (the fourth proportional line)
- F: a medium segment (the line by whose square C is more powerful than D)

(This figure belongs to the demonstration of the square-difference proportionality theorem — Euclid X.14 — carried over from the preceding page.)

so that, as the square on E is to the square on B, so is the square on F to the square on D. And therefore it will also hold that, as the line E is to the line B, so the line F to the line D [Margin: b. 22.sextri = *Elements* VI.22]; and by inversion, as B is to E, so D to F. Since, then, as A is to B, so C to D, and as B to E, so D to F, it follows also, *ex aequali*, that as A is to E, so C to F. Therefore, if A is commensurable in length with E, then C too will be commensurable in length with F; and if A is incommensurable in length with E, then C too will be incommensurable in length with F, as we set forth in the scholium of proposition 10 of this book. Therefore, if four straight lines be proportional, and so on. Which was to be demonstrated.

SCHOLIUM

By the same argument we shall show that, if E be commensurable in power only with A, then F is commensurable in power only with C, as is clear from what we wrote in the scholium of proposition 10 of this book.

THEOR. 13. PROPOS. 16.

[Margin: xv. / ix.]

If two commensurable magnitudes be added together, the whole magnitude will also be commensurable with each of them. And if the whole magnitude be commensurable with one of them, then the original magnitudes will also be commensurable.

Diagram. A tall vertical line divided into segments, with a short separate segment beside it representing the common measure :

- C: top endpoint of the whole line
- B: a division point on the line
- A: bottom endpoint (so the whole line is A–C, composed of the parts AB and BC)
- D: a short separate segment to the left, the common measure

Let two commensurable magnitudes AB, BC be added together. I say that the whole magnitude AC too is commensurable with each of them, AB and BC. For let D be the common measure of AB, BC [Margin: a. 13.dec. = *Elements* X.13]. Since, then, D measures both AB and BC, D will also measure the whole AC composed of them [Margin: b. 1.pron. = Axiom 1 of Book X]. Since, therefore, D measures AC and AB, AC and AB will be commensurable; and likewise, since D measures AC and BC, AB and BC too will be commensurable. And accordingly AC will be commensurable with each of them, AB and BC.

But now let the whole AC, composed of AB, BC, be commensurable with one of them, namely with AB. I say that AB and BC too are commensurable with each other. For let D be the common measure of AC, AB [Margin: c. 3.dec. = *Elements* X.3]. Since, then, D measures the whole AC and the subtracted AB, D will also measure the remainder BC [Margin: d. 9.pro. = *Elements* X.9]. Therefore, since D measures both AB and BC, AB and BC will be commensurable with each other. By the same argument we shall show AB, BC to be commensurable if AC be commensurable with BC. Therefore, if two commensurable magnitudes be added together, and so on. Which was to be shown.

COROLLARIVM

From this it follows that, if a whole magnitude composed of two parts be commensurable with one of them, it is also commensurable with the remaining part. Thus, if AC be commensurable with AB, then AC is also commensurable with the remaining BC. For, as was shown in the latter part of the theorem, D, the common measure of the whole AC and the subtracted AB, since it measures the

whole AC and the subtracted AB, will also measure the remainder BC, by the 3rd axiom. Therefore AC, BC are commensurable. Which is what was proposed.

THEOR. 14. PROPOS. 17.

[Margin: xvj. / ix.]

If two incommensurable magnitudes be added together, the whole magnitude will also be incommensurable with each of them. And if the whole magnitude be incommensurable with one of them, then the original magnitudes will also be incommensurable.

Diagram. A tall vertical line divided into segments, with a short separate segment beside it for the assumed common measure :

- C: top endpoint of the whole line
- B: a division point on the line
- A: bottom endpoint (the whole line A–C is composed of AB and BC)
- D: a short separate segment, the assumed (impossible) common measure

Let two incommensurable magnitudes AB, BC be added together. I say that the whole magnitude AC too is incommensurable with each of them, AB and BC. For if it is not incommensurable with each, let it be commensurable with one of them, if that be possible, namely with AB; and let D be the common measure of AC, AB [Margin: a. 3.dec. = *Elements* X.3]. Since, then, D measures the whole AC and the subtracted AB, D will also measure the remainder BC [Margin: b. 3.pron. = Axiom 3 of Book X]. And therefore, since D measures both AB and BC, AB and BC will be commensurable. But this is absurd, for they were assumed incommensurable. Therefore AC is not commensurable with AB; and by the same reasoning it will not be commensurable with BC either. Therefore it is incommensurable with each of them, AB and BC.

But now let the whole AC, composed of AB, BC, be incommensurable with one of them — that is, with one of the components, namely with AC [recte: AB]. I say that AB, BC too are incommensurable. For if they were commensurable, the whole AC would also be commensurable with each of them, AB and BC [Margin: c. 16.dec. = *Elements* X.16]. But this is absurd; for AC is assumed incommensurable with one of them, namely with AB. Therefore AB, BC are not commensurable. By the same argument we shall show AB, BC to be incommensurable if AC be incommensurable with BC. Therefore, if two incommensurable magnitudes be added together, and so on. Which was to be shown.

COROLLARIVM

It follows from these results that, if a whole magnitude composed of two parts be incommensurable with one of them, it is also incommensurable with the remaining part. Namely, if AC be incommensurable with AB, then AC is also incommensurable with the remaining BC. For if AC were commensurable with BC, then AC would also be commensurable with the remaining AB, by the corollary of the preceding proposition. But this is absurd, since it is assumed incommensurable. Therefore AC is not commensurable with BC. Which is what was proposed.

SCHOLIVM

It is clear that, in the two immediately preceding propositions and their corollaries, if lines are in question, the lines must be understood as commensurable or incommensurable **in length**. For in the demonstration of each proposition a common measure D is assumed, and so on; and only lines commensurable in length with one another possess such a measure, as is clear from the definition.

LEMMA I

If to some straight line there be applied a parallelogram deficient by a square figure, the applied parallelogram is equal to the rectangle contained by the segments of the straight line made by the application.

We demonstrated this lemma in the scholium of proposition 28 of book 6.

LEMMA II

Given two unequal straight lines, to apply to the greater the fourth part of the square described on the lesser, so that the applied figure be deficient by a square.

Although what is proposed in this lemma can be accomplished from proposition 28 of book 6 — since the fourth part of the square described on the lesser line is less than the [figure] applied to half of the greater line, deficient by a square figure, as that proposition 28 of book 6 requires; that is, the square described on half of the lesser line (which is a fourth part of the square described on the whole [lesser line], by the scholium of proposition 4 of book 2) [is less than the figure] described on half of the greater line (which is applied to the half of the greater line, and is deficient by a square figure). Although, I say, this can be accomplished

by proposition 28 of book 6, I prefer nonetheless to carry out this very thing here, together with other commentators, by another and easier method.

Let there be given, then, two unequal straight lines AB, CD, of which AB is the greater; and let it be required to apply to AB a parallelogram deficient by a square figure, this parallelogram being equal to the fourth part of the square described on the line CD. Let the lines AB, CD be bisected at E and F; and from center E, with radius EA or EB, let the semicircle AGB be described; and from E let EG be drawn perpendicular to AB. And since the whole AB is assumed greater than the whole CD, AE — the half of AB, that is EG, which is equal to AE — will also be greater than CF, the half of CD. Then, EH being set equal to CF, let HI be drawn through H parallel to AB, and let IKL be dropped perpendicular to AB, and let KL be equal to KB; and finally let the rectangle AL and the square BL be completed. I say that the parallelogram AL, applied to the line AB and deficient by the square figure BL, is equal to the fourth part of the square on CD.

For since KI is the mean proportional between AK, KB, as we set forth in the scholium of proposition 13 of book 6, the rectangle under AK, KB — that is, the rectangle AL — will be equal to the square on KI [Margin: d. 17.sexti = *Elements* VI.17], that is, to the square on EH [Margin: e. 34.primi = *Elements* I.34] (for KI is equal to EH, because of the parallelogram EI), that is, to the square on CF. But the square on CF is the fourth part of the square on CD, since the square on CD, by the scholium of proposition 4 of book 2, is quadruple the square on CF. Therefore the parallelogram AL, applied to the line AB and deficient by the square BL, is equal to the fourth part of the square described on CD. Which is what was proposed.

Diagram. A semicircle standing on a horizontal diameter, with an inscribed rectangle and a separate divided line-segment below :

- B: left endpoint of the diameter
- A: right endpoint of the diameter
- G: apex (top) of the semicircle, above the center
- E: center of the diameter BA (foot of the perpendicular radius EG)
- I: upper-left corner of the inscribed rectangle (on the semicircle)
- H: upper-right corner of the inscribed rectangle
- K: point on the diameter, foot of the perpendicular IK (dropped to the left of E)
- L: point below the diameter, on the extension of IK (with KL equal to KB)

- Separate lower segment (the lesser line CD, bisected): left endpoint D [?] (printed glyph unclear, resembles a barred *h*), midpoint F, right endpoint C

SCHOLIUM

From this lemma we shall also solve the following problem, in this manner:

To cut a given straight line so that the rectangle contained by the parts be equal to a given rectilinear figure — provided, however, that this figure be not greater than the square described on half the line.

For let AB be the given straight line, and any rectilinear figure to which the square on CF is set equal — this square being not greater than the square on the half AE, so that the side CF be not greater than the side AE. Then, the perpendicular EG having been erected on AB, let EH be equal to CF. Next, HI having been drawn parallel to AB, let IK be dropped perpendicular to AB. When this is done, we shall show, as before, that the rectangle under the parts AK, KB is equal to the square on IK, that is, to the square on EH, that is, to the square on CF. Which is what was proposed. Now we said that the given rectilinear figure ought not to be greater than the square described on half the line; because, if it were greater, the line CF would also be greater than the line EG. Then a line equal to CF could not be cut off from EG — which is nevertheless required for effecting the problem, as is clear from the demonstration.

LEMMA III

If there be two unequal straight lines, and to the greater there be applied the fourth part of the square described on the lesser, deficient by a square figure, the segments made by the application will not be equal.

Let there be two unequal straight lines AB and C; and to the greater, AB, let there be applied a parallelogram deficient by a square, this being equal to the fourth part of the square described on the lesser, C, in such a way that DB is the side of the square by which the applied parallelogram is deficient. I say that the segments AD, DB are unequal. For if the segments AD, DB were said to be equal — since, by the first lemma, the parallelogram applied to AB and deficient by the square figure described on DB is equal to the rectangle under AD, DB, while that which is contained under the equals AD, DB is a square — the said parallelogram would be the square described on AD, [which is] half of AB; and therefore, by the scholium of proposition 4 of book 2, the square on AB would be quadruple that parallelogram. But the square on C is also, by hypothesis, quadruple the same applied parallelogram, namely quadruple the fourth part of the square on C.

Therefore the squares on the lines AB and C are equal, and the lines AB and C themselves are equal. But this is absurd, for they are assumed unequal, with AB the greater. Therefore the segments AD, DB are unequal. Which is what was proposed.

This is also easily seen from the construction of the problem in the preceding lemma. For since, by the construction, EH was cut off equal to the half part of CD, namely to CF, and HI was drawn parallel to AB, and finally the perpendicular IK was dropped, so that the parts made by the application are AK, KB — it is clear that the segments AK, KB are unequal, since AB was bisected at E. Indeed, from this it is established that the first segment is the greater, and the latter — which is the side of the square by which the applied parallelogram is deficient — is the smaller.

Diagram. A vertical line divided at one point, with a shorter separate segment beside it :

- B: top endpoint of the greater line
- D: division point (so the greater line is divided into AD and DB)
- A: bottom endpoint of the greater line
- C: a shorter separate segment to the right (the lesser line)

THEOR. 15. PROPOS. 18.

[Margin: xvij. / xij.]

If there be two unequal straight lines, and if to the greater there be applied a parallelogram equal to the fourth part of the square [made] on the lesser, deficient by a square figure, and it divides [the greater] into parts commensurable in length: then the greater will be more powerful than the lesser by the square on a straight line commensurable in length with itself. And if the greater be more powerful than the lesser by the square on a straight line commensurable in length with itself, and if to the greater there be applied a parallelogram equal to the fourth part of the square [made] on the lesser, deficient by a square figure: then it will divide [the greater] into parts commensurable in length.

Diagram. A vertical line marked at several points, with a shorter separate segment beside it. From top to bottom on the main line:

- B: top endpoint of the greater line AB
- D: division point (with AD the greater segment, DB the lesser)

- E: bisection point (midpoint) of AB
- F: point taken so that EF equals ED
- A: bottom endpoint
- C: a shorter separate segment to the right (the lesser line)

Let there be two unequal straight lines AB and C, of which AB is the greater; and, by the second lemma of the preceding proposition, let there be applied to AB a parallelogram equal to the fourth part of the square described on the lesser, C, and deficient by a square figure, contained under AD, DB, and let it make the segments AD, DB commensurable in length. I say that AB is more powerful than C by the square on a line commensurable in length with itself.

For since, by the third lemma of the preceding proposition, AD is greater than DB, let AB be bisected at E, and let EF be taken equal to ED. This done, since the wholes EA, EB are equal, and the subtracted EF, ED are equal too, the remainders AF, BD will also be equal. And since the line AB is bisected at E but not bisected at D, the rectangle under AD, DB together with the square on ED will be equal to the square on EB [Margin: a. 5.sec. = *Elements* II.5]; and therefore quadruple the rectangle under AD, DB, together with [quadruple] the square on ED, will be equal to quadruple the square on EB. But the square on C is equal to quadruple the rectangle under AD, DB (for the rectangle under AD, DB is assumed equal to the fourth part of the square on C); and the square on FD is equal to quadruple the square on ED (for the square on FD is, by the scholium of proposition 4 of book 2, quadruple the square on ED, since FD is double ED); and the square on AB is equal to quadruple the square on EB (which square on AB is, by the scholium of proposition 4 of book 2, quadruple the square on EB, EB being half of AB).

Therefore the squares on C and FD together are equal to the square on AB. And accordingly the line AB is more powerful than the line C by the square on the line FD. This FD, then, must be shown to be commensurable in length with AB. Since the lines AD, DB are assumed commensurable in length, the whole AB will also be commensurable in length with the part DB [Margin: b. 16.dec. = *Elements* X.16]. But the [line] composed of DB, AF is also commensurable in length with DB (since the [line] composed of DB, AF is double DB). Therefore, since both AB and the [line] composed of DB, AF are commensurable in length with DB, AB and the [line] composed of DB, AF will also be commensurable in length with each other [Margin: c. 12.dec. = *Elements* X.12]. And accordingly, since AB [and] the [line] composed of AF, DB...

Euclid, Book X (Clavius's commentary) — irrational magnitudes

(Global printed folios 415–417. Running headers: recto "LIBER X.", verso "EVCLID. GEOM.")

[Conclusion of Proposition 18 — "more powerful by a commensurable square"]

(Continued from the previous page; the direct demonstration is being completed.)

of DB, taken as one, and of FD, is commensurable in length with the composite of AF and DB. Therefore, by the corollary to Proposition 16 of this book, AB itself is commensurable in length with the remaining part FD. Hence AB is more powerful than C by the square on the straight line FD, which is commensurable in length with AB.

[Converse.] Now let AB be more powerful than C by the square on a straight line commensurable in length with itself, and let a parallelogram equal to the fourth part of the square on C be applied to AB, deficient by a square figure, making the segments AD and DB. I say that the straight lines AD and DB are also commensurable in length. For with the same construction we shall likewise show that AB is more powerful than C by the square on FD. Therefore, since AB is assumed to be more powerful than C by the square on a straight line commensurable in length with itself, the straight line AB is commensurable in length with FD. And since the whole AB — composed of FD and of AF, DB (taken as one) — is commensurable in length with FD, AB is by the corollary to Proposition 16 of this book also commensurable in length with the remaining composite of AF and DB. But the composite of AF and DB is commensurable in length with DB, since it is double of it. Therefore, since each of AB and DB is commensurable in length with the composite of AF and DB, AB and DB are also commensurable in length with each other [Margin: d. 12.dec. (*Elements* X.12)]. And accordingly, since the whole AB, composed of AD and DB, is commensurable in length with DB, the lines AD and DB are likewise commensurable in length with each other [Margin: e. 16.deci. (*Elements* X.16)]. Therefore, if there be two unequal straight lines, and so on. Which was to be demonstrated.

THEOR. 16. PROPOS. 19.

[Margin (divergent proposition numbering, as printed): xviii. / xiiij.]

If there be two unequal straight lines, and to the greater there be applied a parallelogram equal to the fourth part of the square on the less and deficient by a square figure, which divides the greater into parts incommensurable in length, then the greater is more powerful than the less by the square on a straight line incommensurable in length with itself. And if the greater is more powerful than the less by the square on a straight line incommensurable in length with itself, and to the greater there be applied a parallelogram equal to the fourth part of the square on the less and deficient by a square figure, then it divides the greater into parts incommensurable in length.

[Demonstration — direct.] Let there be two unequal straight lines AB and C, of which AB is the greater. Let a parallelogram equal to the fourth part of the square on C be applied to AB — by the second lemma of the preceding proposition — deficient by a square figure, so that it makes on the straight line AB the parts AD and DB, incommensurable in length. I say that AB is more powerful than C by the square on a straight line incommensurable in length with itself. For, with the same things constructed as above, we shall likewise show that AB is more powerful than C by the square on FD. It must therefore be demonstrated that this FD is incommensurable in length with AB[?]. Since the straight lines AD and DB are assumed to be incommensurable in length, the whole AB is also incommensurable in length with the part DB [Margin: a. 17.dec. (*Elements* X.17)]. But DB is commensurable in length with the composite of DB and AF, since this composite is double of DB. Therefore, of the two commensurable lines — DB and the composite of DB and AF — since DB is incommensurable in length with the straight line AB, the remaining composite of DB and AF is also incommensurable in length with AB [Margin: b. 14.dec. (*Elements* X.14)]. And on that account, since AB — composed of AF, DB (taken as one) and of FD — is incommensurable in length with the composite of AF and DB, AB is by the corollary to Proposition 17 of this book also incommensurable in length with the remaining part FD. Therefore AB is more powerful than C by the square on FD, which is incommensurable in length with itself.

Diagram. A tall vertical straight line AB (A at the foot, B at the top), divided by the intermediate points D, E, F (in order from the top: B, D, E, F, A); beside it, to the right, a separate shorter vertical straight line C. The figure illustrates AB cut at D into the parts AD, DB, with E the midpoint and F the further division point, and C the second given line.

- B (top of the left line): endpoint of AB

- D (upper division): point of division of AB into AD, DB
- E (middle): bisection point of AB
- F (lower division): auxiliary point ($EF = ED$)
- A (foot of the left line): endpoint of AB
- C (foot of the right line): the second, lesser given line

[Demonstration — converse.] Now let AB be more powerful than C by the square on a straight line incommensurable in length with itself, and let a parallelogram equal to the fourth part of the square on C be applied to AB, deficient by a square figure, making on the straight line AB the parts AD and DB. I say that the straight lines AD and DB are also incommensurable in length. For, with the same things constructed, we shall show as before that AB is more powerful than C by the square on FD. Therefore, since AB is assumed to be more powerful than C by the square on a straight line incommensurable in length with itself, AB is incommensurable in length with FD. And since the whole AB — composed of FD and of AF, DB (taken as one) — is incommensurable in length with FD, AB is by the corollary to Proposition 17 of this book also incommensurable in length with the remaining composite of AF and DB. But the composite of AF and DB is commensurable in length with DB, since the former is double of the latter. Therefore, of the two commensurable lines — namely the composite of AF and DB, and DB — since the composite of AF and DB is incommensurable in length with the straight line AB, the remaining line DB is also incommensurable in length with AB [Margin: c. 14.dec. (*Elements* X.14)]. And accordingly, since the whole AB, composed of AD and DB, is incommensurable in length with DB, the lines AD and DB are themselves incommensurable in length with each other [Margin: d. 17.dec. (*Elements* X.17)]. For which reason, if there be two unequal straight lines, and to the fourth part of the square, and so on. Which was to be demonstrated.

SCHOLIUM

Euclid has thus far dealt with commensurable and incommensurable magnitudes; in what follows he passes to Rational and Medial lines.

LEMMA I.

Since it has been demonstrated that lines commensurable in length are altogether commensurable in square as well, whereas lines commensurable in square are not altogether commensurable in length also, but are only *able to be* commensurable in length as well — it is clear that, if some line be commensurable in length with the assigned Rational

line, that line is called Rational, and is commensurable with the assigned line not only in length but also in square; for lines commensurable in length are altogether commensurable in square too. But if some line be commensurable in square with the assigned Rational line — provided it be commensurable in length as well — it too will be called Rational, and commensurable with that line both in length and in square. And if some line, being again commensurable in square with the assigned Rational line, be incommensurable with it in length, it too will be called Rational, commensurable with it in square only.

LEMMA II.

From Proclus. He calls Rational those lines that are commensurable with the assigned Rational line either in length and in square, or in square only. But there are also other lines that are indeed incommensurable in length with the assigned Rational line, yet commensurable in square only; and for that reason these too are called Rational, and commensurable with one another insofar as they are Rational — commensurable, I mean, with one another either in length and in square, or in square only. And if indeed they are commensurable in length, they themselves are said to be Rational, commensurable with one another in length, it being understood that they are commensurable in square as well; but if they are commensurable with one another in square only, they themselves are also said to be Rational, commensurable with one another in square only.

SCHOLIVM

And so from these things it will be possible to gather three kinds of Rational lines commensurable in length with one another. For, of two Rational lines commensurable in length with one another, either one is equal to the assigned Rational line — and hence both are commensurable in length with the Rational line too; or neither is equal to the assigned Rational line, yet both are commensurable with it in length; or, finally, both are commensurable with the assigned Rational line in square only. These three kinds we shall find in the following way.

Let the Rational line A be assigned, divided into four parts — as many, that is, as there are units in the number B. Then, having taken any other number C, let D be one straight-line part of A; and however many times D measures the line A, let it measure just so many times another line E. Likewise, however many units there

are in C, let the same D measure just so many times another line F. Now since A and E are composed of parts equal in number, which are indeed equal in magnitude to D, they will be equal to one another. Again, since D measures all three — A, E, and F — the three A, E, and F will all be commensurable in length. Therefore E and F, being commensurable in length with the Rational line A, are Rational; and they have also been shown to be commensurable in length with one another, since they have D as a common measure. There have thus been found two Rational lines, E and F, commensurable in length both with one another and with the assigned Rational line A, and of which one, namely E, is equal to the assigned Rational line A.

[Margin: a. 11.dec. (*Elements* X.11)]

Diagram. Four vertical straight lines. At their feet, from left to right, the labels A, B, E, F. The leftmost line A is undivided; the adjacent line carries the interior markings D (the common part) and the point C, with the numerals 6 and 4 written beside it; the lines E and F are subdivided into equal parts. The figure represents the assigned line A divided by the measure D, and the derived commensurable lines. [The individual tick-subdivisions and the exact placement of the numerals 6 and 4 are not resolvable cell-by-cell at this resolution.]

- A (foot, leftmost): the assigned Rational line
- B (foot): the number of equal parts (shown as a divided line; numeral 4)
- D (interior mark): the common part / measure
- C (interior mark; numeral 6): the auxiliary number
- E (foot): line commensurable with A (equal to A)
- F (foot): line commensurable with A

Now let D measure two other lines C and E, by two numbers F and G, of which neither is the same as B, in such a way that each of the lines C and E is unequal to A. Then, as before, the three straight lines A, C, E — having the common measure D — will be commensurable in length. Therefore C and E, being commensurable in length with the Rational line A, are Rational. And since they are also commensurable in length with one another, there will have been found two Rational lines C and E, commensurable in length both with one another and with the assigned Rational line A, of which neither is equal to the assigned Rational line A.

Diagram. A group of horizontal straight lines, stacked, each subdivided into equal parts by tick marks. The visible left-hand labels are A, B, C, and a fourth line; the numeral 4 and the point D are marked on the second line. The figure

illustrates the second construction (the lines measured by the common part D through the numbers F, G). [The exact labelling and tick counts of these short scored segments are at the resolution floor; the fourth line's label is not legible.]

- A (top segment): line measured by D
- B (with numeral 4): auxiliary
- D: the common measure
- C: line commensurable with A
- [fourth segment: label illegible [?]]

Finally, with the Rational line A assigned, let there be found a straight line B incommensurable with it in length only [Margin: a. 11.dec. (*Elements* X.11)]; let B be cut into any number of equal parts, and let C be taken, composed of any other number of parts equal in magnitude to the parts of B. This done, B and C will be commensurable in length. I say that they are commensurable with the assigned Rational line A in square only. For since A and B are commensurable in square, the square on A is commensurable with the square on B. But the square on C is commensurable with the same square on B, because B and C are commensurable in length, and hence in square as well [Margin: b. 12.dec. (*Elements* X.12)].

Therefore the squares on the straight lines A and C are also commensurable with one another. Hence C is commensurable in square with A. And since, of the two straight lines B and C commensurable in length, B is incommensurable in length with A, the remaining line C is also incommensurable in length with A [Margin: c. 14.deci. (*Elements* X.14)]. Therefore C is commensurable with A in square only. And since B and C, being commensurable in square with the assigned Rational line A, are Rational, there will have been found two Rational lines B and C, commensurable in length indeed with one another, but commensurable with the assigned Rational line A in square only. Which is what was proposed.

Diagram. Three vertical straight lines, at whose feet stand the labels A, B, C. Line A (leftmost) is drawn solid and undivided; lines B and C are subdivided into equal parts by tick marks. The figure illustrates A (assigned Rational), B (incommensurable with A in length only), and C (composed of equal parts of B).

- A (foot, leftmost): the assigned Rational line
- B (foot, middle): incommensurable with A in length only
- C (foot, right): composed of parts equal to the parts of B

(Page 3 — global p. 429, printed folio 417, "LIBER X.")

And if anyone should wish to find any number of Rational lines commensurable in length with one another, he will accomplish it in this way. Taking any measure A, let there be composed any number of lines B, C, D out of as many parts equal to A as there are units in the same number of unequal numbers E, F, G. For the lines B, C, D, having the common measure A, will be commensurable in length.

Moreover, that all Rational lines are commensurable not only with the assigned Rational line but also with one another, we shall easily demonstrate in this way. Rational lines are those commensurable with the assigned Rational line either in length and in square, or in square only [Margin: d. 6.def. (*Elements* X, def. 6)]; and lines commensurable with the same line are commensurable with one another as well [Margin: e. 12.[?] (*Elements* X.12; the abbreviation appears to read "sexti," i.e. VI, but the argument invokes X.12)]. It is therefore clear that any Rational lines whatever are commensurable with one another.

Diagram. Four vertical straight lines, at whose feet stand the labels A, B, C, D (left to right). The leftmost, A, is the shortest (the common measure). Beside the second line stand the labelled numbers G 4, F 5, E 3; the lines B, C, D are subdivided into equal parts. The figure illustrates the lines B, C, D built from equal parts of the common measure A, according to the numbers E, F, G.

- A (foot, leftmost): the common measure
- B, C, D (feet): the Rational lines commensurable in length
- E (numeral 3), F (numeral 5), G (numeral 4): the unequal numbers giving the counts of parts

LEMMA III.

If there be two straight lines, then as the first is to the second, so is the square on the first to the rectangle contained by those two straight lines; and as the second is to the first, so is the rectangle contained by them to the square on the first.

[Demonstration.] Let there be two straight lines A and B. I say that as A is to B, so is the square on A to the rectangle contained by A and B. For from any straight line CD let CE be cut off equal to A, and EF equal to B. Then on CE let the square CG be described, and let the rectangle GF be completed, contained by CE and EF — that is, by A and B. Now since, as CE is to EF (that is, as A is to B), so is the parallelogram CG (that is, the square on A) to the parallelogram GF contained by A and B [Margin: f. (*Elements* VI.1) [?] — the printed reference is not clearly legible], it is evident that, if there be two straight lines, the first is to the second as the square described on the first is to the rectangle contained by them. In the

same way, as B is to A, so will the rectangle FG be to the square GC. Which is what was proposed.

Diagram. At the top, two horizontal reference lines, the upper labelled A and the shorter one below it labelled B. Below them, a straight line CD (C at the left, D at the right) marked at the interior points E and F, so that $CE = A$ and $EF = B$. On CE a square is described (its lower part reaching the point G), giving the square CG; on EF the rectangle GF is completed. The whole stands as a rectangle divided by verticals at E and F.

- A, B (top): the two given lines
- C (top-left of the figure): endpoint of the base line
- E: point with $CE = A$
- F: point with $EF = B$
- D (top-right): endpoint of the base line CD
- G (below): lower corner of the square CG / the completed rectangle GF

LEMMA IV.

A space commensurable with a Rational space is itself also Rational.

[Demonstration.] Let the space A be commensurable with the Rational space B. I say that A too is Rational. For let C be the Rational square, by reference to which the remaining spaces are called Rational or Irrational — the square, that is, described on the assigned Rational line. Now since B is Rational, it is commensurable with the Rational square C [Margin: g. 9.def. (*Elements* X, def. 9)]. But A is also commensurable with B. Therefore, since A and C are both commensurable with B, they will be commensurable with one another as well [Margin: h. 12.dec. (*Elements* X.12)]; and accordingly the space A, being commensurable with the Rational square C described on the assigned Rational line, is Rational [Margin: i. 6.def. (*Elements* X, def. 6)]. Which was to be demonstrated.

Diagram. Three rectangular areas set side by side, labelled A, B, C. A and B are tall, narrow rectangles; C (rightmost) is a larger square. The figure represents the space A, the Rational space B, and the Rational square C.

- A: the space in question
- B: the Rational space
- C: the Rational square described on the assigned Rational line

THEOR. 17. PROPOS. 20.

[Margin (divergent proposition numbering, as printed): xix. / xv.]

The rectangle contained by Rational straight lines commensurable in length, according to any of the aforesaid modes, is Rational.

[Demonstration.] Let the Rational line A be assigned, and let the rectangular space BD be contained by the Rational lines BC, CD, commensurable in length according to some one of the aforesaid modes — that is, according to some one of the three modes we explained in the second scholium of the preceding proposition — so that either one of the lines BC, CD is equal to the assigned Rational line A, or neither is, yet each is commensurable with it either in length or in square only. I say that the rectangle BD is Rational. For let there be described, on one of them, namely on BC, the square BE. Now since the Rational line BC is commensurable with the assigned Rational line A either in length and in square, or in square only, the square BE described on BC is also commensurable with the square on A [Margin: a. 3.defin. (*Elements* X, def. 3)]...

Diagram. At the top, a separate horizontal straight line labelled A (the assigned Rational line). Below it, a rectangle whose bottom edge runs from E (left) through C (middle) to D (right), with a vertical division rising from C to the point B on the top edge. The left cell is the square BE (described on BC), the right cell is the rectangle BD (contained by BC and CD).

- A (top): the assigned Rational line
- B (top, over C): upper endpoint of the dividing side BC
- E (bottom-left): far corner of the square BE
- C (bottom-middle): foot of the dividing side
- D (bottom-right): far corner of the rectangle BD

(The demonstration continues on the following page.)

Euclid, *Elements*, Book X (continued)

[End of PROPOS. 20 — the rational rectangle]

commensurable. [Margin: b — *Elements* X, def. 8] Now the square on A is rational — the standard by reference to which the remaining magnitudes are called rational or irrational. [Margin: c — *Elements* X, def. 9] Therefore BE too, being commensurable with it, is rational. And since BC — that is, EC — and CD are commensurable in length (for BC and CD were assumed to be rationals

commensurable with one another in length), [Margin: d — *Elements* VI.1] and as EC is to CD, so is EB to BD, [Margin: e — *Elements* X.10] EB and BD will also be commensurable. Hence, by lemma 4 of the preceding proposition, BD, being commensurable with the rational BE, is rational. Therefore what is contained by rational straight lines commensurable in length, and so on. Which was to be demonstrated.

THEOR. 18. PROPOS. 21.

[Margin: xx. / xvi.]

If a rational [area] is applied to a rational [line], it produces a rational breadth, commensurable in length with the line to which it is applied.

Let a rational line A be set out again, and another rational line BC — related to it in one of the ways we explained in the second scholium of proposition 19; that is, whether BC is equal to the rational line A set out or not, it is at any rate commensurable with it either in length and in square, or in square only. Let a rational [area] BD be applied to BC, producing the breadth CD. I say that CD is rational and commensurable in length with BC.

For let the square BE be described on BC; this we shall show to be rational, just as in the preceding proposition. Since, then, BE and BD are rational, [Margin: a — *Elements* X, def. 9] they will be commensurable with the square described on the rational line A that was set out; [Margin: b — *Elements* X.11] and therefore they will also be commensurable with one another. [Margin: c — *Elements* VI.1] Now as BE is to BD, so is EC — that is, BC — to CD. Therefore BC and CD too are commensurable in length, as we taught in the scholium of proposition 10 of this book. So CD is commensurable in length with BC; [Margin: d — *Elements* X, def. 6] and it is also rational, since it is commensurable with the rational BC, and hence with the rational line A that was set out, as we demonstrated in the scholium of proposition 12 of this book. Therefore the breadth CD is rational and commensurable in length with BC. So if a rational is applied to a rational, it produces a breadth, and so on. Which was to be demonstrated.

Diagram. A rational line A is drawn as a horizontal segment (with division ticks) at the top. Below it stands a large rectangle divided by a vertical line into a left square and a right rectangle.

- A (top): the rational line set out.
- B (top-centre): apex of the vertical dividing line; shared top corner of the square and the rectangle.

- E (bottom-left): far corner of the square BE described on BC.
- C (bottom-centre): foot of the dividing line (foot of BC).
- D (bottom-right): far corner of the applied rectangle BD, whose breadth is CD.

LEMMA I.

A straight line whose square is an irrational area is itself irrational.

Let the straight line A have as its square an irrational area — that is, let the square on A be equal to some irrational area. I say that A is irrational. For if it were called rational, its square would be rational too, as was shown in the demonstration of proposition 20 of this book. But that is absurd, since the area is assumed to be irrational. Therefore A is not rational; hence it is irrational.

The same thing is also clear from definition 11 of this book, where lines whose squares are irrational areas are called irrational.

Diagram. A single vertical straight line labelled A.

- A: the straight line whose square is an irrational area.

LEMMA II.

To find two rational straight lines commensurable in square only.

There are two kinds of rational lines commensurable with one another in square only: either one of them is equal to the rational line set out, or neither is. We shall find lines of the first kind as follows. Let a rational line A be set out, and let B be taken equal to it. Then let C be found [Margin: e — *Elements* X.11]

incommensurable in length only with B — or, what is the same, commensurable in square only. Since, then, B and C are commensurable with A (B indeed because it is equal to it; and C by construction, because it was found to be commensurable in square only with B, and hence with A), B and C will be rational; and they are also commensurable in square only. Two rationals B, C have therefore been found, one of which, namely B, is equal to the rational line A set out.

Diagram. Three vertical straight lines side by side, labelled A, B, C at their feet; A carries interior division ticks.

- A: the rational line set out.
- B: taken equal to A.
- C: found commensurable in square only with B.

We shall find lines of the second kind by this method. Let a rational line A be set out again, and let B be found [Margin: f — *Elements* X.11] incommensurable in length only with it; and again let C, greater or less than A, be found incommensurable in length only with B. I say that B and C are rational and commensurable in square only. That they are commensurable in square only is clear from the construction. That they are rational we shall show thus. Since A and C are commensurable in square with B, A and C will also be commensurable in square, as we demonstrated in the scholium of proposition 12 of this book. Therefore, since both B and C are commensurable in square with the rational line A set out, [Margin: g — *Elements* X, def. 6] B and C will be rational. So B and C have been found: rational and commensurable in square only.

Diagram. Three vertical straight lines side by side, labelled A, B, C at their feet, of increasing length (C tallest); A carries interior division ticks.

- A: the rational line set out.
- B: incommensurable in length only with A.
- C: incommensurable in length only with B, greater or less than A.

SCHOLIUM.

If any number whatever of rational lines commensurable with one another in square only are to be found, we shall carry it out in this way.

By what we taught in the scholium of proposition 20 of book 9, let as many prime numbers be taken as there are rational lines sought — namely A, B, C, D. Then, taking a rational line E, let it be arranged that as A is to B, so is the square on E to the square on F, as we showed in the corollary of proposition 6 of this book. Likewise, as B is to C, so let the square on F be to the square on G; and finally, as C is to D, so let the square on G be to the square on H. I say that the lines E, F, G, H are rational and commensurable with one another in square only.

That they are rational is evident. For since their squares have the ratio that the numbers A, B, C, D have (namely, the square on E to the square on F as the number A to the number B, by construction; likewise the square on F to the square on G as B to C, and the square on G to the square on H as C to D; while, *ex aequali*, the square on E is to the square on G as A to C; likewise the square on E to the square on H as A to D; and finally the square on F to the square on H as B to D), [Margin: h — *Elements* X.6] they will be commensurable with one another;

and therefore the lines themselves too will be commensurable at least in square. So, E being rational, the remaining lines F, G, H will also be rational.

That they are commensurable in square only we shall show thus. Since their squares are proportional to the prime numbers A, B, C, D, and prime numbers do not have to one another the ratio that square numbers have, as we taught at the end of book 8, the squares of the lines E, F, G, H likewise will not have the ratio that square numbers have. [Margin: i — *Elements* X.9] Therefore the lines E, F, G, H are incommensurable in length. But they were shown to be rational and commensurable in square. They are therefore rational and commensurable in square only. Which was what was proposed.

Diagram. Above the figure, a row of the four assigned prime numbers is printed under their letters: A = 5, B = 7, C = 3, D = 2. Below stand four vertical straight lines labelled E, F, G, H at their feet, of differing lengths (F tallest).

- A = 5, B = 7, C = 3, D = 2 (the four prime numbers).
- E, F, G, H: the four rational lines whose squares are in the ratios of these numbers.

If, given any number of rationals commensurable in square only, yet another is to be found commensurable in square only with all of them, [it can be done] in this way. Let two rationals commensurable in square only, A and B, be given, whose squares have the ratio that the number C has to the number D. Taking another number E prime to each of C and D (such a number is easily found if one takes a prime that measures neither C nor D), let it be arranged that as D is to E, so is the square on line B to the square on line F, by the corollary of proposition 6 of this book. I say that F is rational and commensurable in square only with A and B.

That it is rational is clear from this: it is commensurable, at least in square, with the rational B, since the squares of the lines B and F, having the ratio of the numbers D and E, [Margin: k — *Elements* X.8] are commensurable. Now since the ratio of D to E is not that of a square number to a square number — as we showed at the end of book 8 (because D and E, which are both non-squares — since E, being prime, is in no way a square — are prime to one another, and therefore not similar plane numbers, and consequently, by what we showed in the scholium of proposition 26 of book 8, do not have the ratio of a square to a square) — [Margin: l — *Elements* X.9] the lines B and F will be incommensurable in length. Therefore they are commensurable in square only.

By the same reasoning A and F will be commensurable in square only. For, *ex aequali*, the square on A will be to the square on F as the number C to the number E. Since, then, these numbers do not have the ratio of a square to a square (which we shall show just as we demonstrated the same for the numbers D and E), A and F will be incommensurable in length, and so on.

Diagram. Above the figure, a row of numbers is printed under their letters: C = 10, D = 6, E = 7. Below stand vertical straight lines labelled A, B, F at their feet.

- C = 10, D = 6, E = 7 (E prime to both C and D).
- A, B: the two rationals commensurable in square only that are given.
- F: the new rational found commensurable in square only with A and B.

THEOR. 19. PROPOS. 22.

[Margin: xxi. / xix.]

The rectangle contained by rational straight lines commensurable in square only is irrational; and the straight line whose square equals it is irrational. Let it be called **medial** [Media].

[p. 432 — *EVCLID. GEOM.*]

Let a rational line A be set out, and a rectangle BD contained by the rationals BC, CD commensurable in square only in one of the ways we described in lemma 2 of the preceding proposition (that is, whether one of them is equal to the rational line A set out, or not). I say that the rectangle BD is irrational, and that the straight line whose square is equal to BD is also irrational — let it be called medial.

For let the square BE be described on one of them, say on BC; this will be rational, as we said in the demonstration of proposition 20. [Margin: a — *Elements* VI.1] And since as EC — that is, BC — is to CD, so is BE to BD; but BC is incommensurable in length with CD, by hypothesis; then, by what we set forth in the scholium of proposition 10 of this book, BE will be incommensurable with BD. [Margin: b — *Elements* X, def. 9] Therefore, since BE is commensurable with the square on the rational line A set out, while BE is incommensurable with BD, [Margin: c — *Elements* X.14] the square on the rational line A set out is also incommensurable with BD. And so BD, being incommensurable with the square on the rational line set out, [Margin: d — *Elements* X, def. 10] is irrational. Wherefore the straight line whose square is BD is also irrational, by lemma 1 of the preceding proposition.

[Margin: e — *Elements* VI.17] Let this line whose square is BD be called **medial**, because it is the mean proportional between the two rationals BC, CD commensurable with one another in square only — since its square is equal to the rectangle BD contained by BC, CD. Therefore what is contained by rationals commensurable in square only, and so on. Which was to be demonstrated.

Diagram. A rational line A is drawn as a horizontal segment (with division ticks) at the top. Below it stands a large rectangle divided by a vertical line into a left square and a right rectangle.

- A (top): the rational line set out.
- B (top-centre): apex of the vertical dividing line; shared top corner of the square and the rectangle.
- E (bottom-left): far corner of the square BE described on BC.
- C (bottom-centre): foot of the dividing line (foot of BC).
- D (bottom-right): far corner of the rectangle BD contained by BC, CD.

SCHOLIUM.

Accordingly, every mean proportional line between two rationals commensurable with one another in square only will be called medial. [Margin: f — *Elements* VI.17] For since its square is equal to the rectangle contained by such rationals — which in this theorem was shown to be irrational — its side, namely the mean proportional between the said rationals, will be an irrational line, which is called medial. From this we may readily describe the medial line by saying that it is the irrational line which is the mean proportional between two rational lines commensurable with one another in square only; or the line whose square can produce the rectangle contained by two rationals commensurable with one another in square only. For this line alone is here called medial.

As Campanus rightly notes here, not only is the straight line whose square is the irrational rectangle contained by two rational lines commensurable in square only irrational and called medial; but also its square, or that rectangle, is called medial, because it is the mean proportional between the squares of those rational lines commensurable in square only, just as the line itself is the mean proportional between the said rationals. For if three lines are in continued proportion — as are BC, the irrational line called medial, and CD — then the rectilinear figures similar and similarly described on them, such as their squares, will also be proportional, as we demonstrated in the scholium of proposition 22 of book 6. Hence the square described on the medial is the mean proportional between the squares of the lines BC, CD, and can therefore be called medial.

But you must not understand this as though you were to think that every medial rectangle is contained by two rational lines commensurable in square only, as is the medial BD. For this is false, since a medial area can also be contained by two irrationals — namely medials commensurable with one another in length, or in square only — as will be established from propositions 25 and 26 of this book. Thus "rectangle contained by two rationals commensurable in square only" and "medial area" are not convertible. For every rectangle contained by two rationals commensurable in square only is medial, as we showed; but not every medial area is contained by two rationals commensurable in square only. Universally, however, every medial area is equal to some other medial contained by two rationals commensurable in square only. For otherwise the line whose square it is would not be called medial, since it could not be the rectangle contained by two rationals commensurable in square only; or it would not be the mean proportional between two rationals commensurable in square only.

Hence a medial can be described thus: let us say it is the rectangle contained by two rationals commensurable in square only; or, at any rate, the rectangle which is equal to some other rectangle contained by two rationals commensurable in square only, such that the straight line called medial in this theorem can produce it. For every medial not contained by two such rationals can be reduced to another medial whose sides are two rational lines commensurable in square only, as we shall show in the scholium of the following theorem.

THEOR. 20. PROPOS. 23.

[Margin: xxii. / xx.]

The square that arises from a medial line, applied to a rational, produces a rational breadth, incommensurable in length with the line to which it is applied.

Let A be a medial line, and BC a rational line — whether it be the one set out or one commensurable in length and square with the one set out. [Margin: a — *Elements* I.45] Let the rectangle BD, equal to the square on the medial A (or to a rectangle equal to that square), be applied to BC, producing the breadth CD. I say that CD is rational and incommensurable in length with BC. For since A is medial, it can produce a rectangle contained by two straight rationals commensurable with one another in square only — otherwise it could not be called medial. Let that rectangle, then, be EG, contained by the rationals EF, FG commensurable in square only.

Diagram. Two rectangles stand side by side, with the medial line A drawn as a short horizontal segment (with ticks) above and between them.

- A (top, centre-right): the medial line.
- Left rectangle (BD): D (top-left), B (bottom-left), C (bottom-right); this is the rectangle BD applied to BC.
- Right rectangle (EG): G (top-right), E (bottom-left), F (bottom-right); this is the rectangle EG contained by EF, FG.

Euclid, *Elements* Book X — Clavius's Commentary (continued)

THEOR. 20. PROPOS. 23 (conclusion of the demonstration)

[Clavius's demonstration, continued from the previous page. The medial line is A; the square on A equals the rectangle BD described on BC; the rectangle EG is contained by EF and FG.]

And since A, by hypothesis, is also the side whose square equals BD, the rectangles BD and EG will be equal; and therefore [Margin b: 14.sext. — *Elements* VI.14] their sides about the equal angles will be reciprocally proportional — that is, BC will be to EF as FG is to CD [Margin c: 22.sexti — VI.22]. And for this reason too, the square on BC will be to the square on EF as the square on FG is to the square on CD. But the square on BC is commensurable with the square on EF (because the straight lines BC and EF are assumed rational, and hence commensurable with one another either in length and in square, or in square only). Therefore [Margin d: 10.dec — X.10] the square on FG will likewise be commensurable with the square on CD; and consequently the straight lines FG and CD will be commensurable at least in square. Now since FG is commensurable with the assigned rational line — if it is not itself the assigned rational line — CD too will be commensurable with the assigned rational line, as we showed in the scholium to Proposition 12 of this book; and so CD, by definition, will be rational. I say that it is also incommensurable in length with BC itself.

For since EF and FG are rational lines commensurable in square only — that is, incommensurable in length — and since EF is to FG as the square on EF is to the rectangle EG contained by EF and FG (by Lemma 3 to Proposition 19 of this book), [Margin e: 10.dec — X.10] the square on EF will be incommensurable with the

rectangle EG, and hence with the rectangle BD, which equals it. But the square on EF is commensurable with the square on CD (because EF and CD are rational, and therefore commensurable at least in square). Therefore, since the square on EF is commensurable with the square on CD, while the rectangle BD is incommensurable with that same square on EF, [Margin f: 13.dec — X.13] the square on CD and the rectangle BD will be incommensurable. But by Lemma 3 to Proposition 19 of this book, the square on CD is to the rectangle BD as the straight line CD is to the straight line BC. [Margin g: 16.dec — X.16] Therefore CD and BC are incommensurable in length. So CD is rational and incommensurable in length with the rational line BC. For this reason, what is applied to a rational line from a medial area, etc. Which was to be demonstrated.

Diagram. Two rectangles side by side, with a short line segment above the right-hand pair.

- A (short segment, upper right): the medial line, drawn with end-ticks.
- Left rectangle, on base BC: B (bottom-left), C (bottom-right), D (top-right); top-left corner unlabeled. This is the square/rectangle BD whose area equals the square on the medial line A.
- Right rectangle, on base EF (wider and lower): E (bottom-left), F (bottom-right), G (top-right); top-left corner unlabeled. This is the rectangle EG contained by EF and FG.

SCHOLIUM.

More easily than by Proposition 45 of Book 1, we shall apply to BC a rectangle equal to the square on A, if — given BC and A — [Margin h: 11.sexiti — VI.11] a third proportional is taken as the side CD. For since BC, A, and CD are proportional, [Margin i: 17.sexiti — VI.17] the rectangle BD contained by the extremes BC and CD will be equal to the square on the mean proportional A.

We shall have to use this technique in what follows as well, whenever a rectangle equal to the square on some straight line is to be applied to a given straight line.

Furthermore, it is clear from this theorem that every medial area — that is, every area whose side is a medial line — is equal to some other rectangle contained by two rational lines commensurable in square only. For if a rectangle equal to that medial area is applied to a rational line, then, by this theorem, it makes the other side rational but incommensurable in length with the rational line. Hence this rectangle, applied and equal to the medial area, will be a medial area contained by two rational lines commensurable in square only. And in this way any medial

area whatever can be reduced to a medial area contained by two rational lines commensurable in square only.

THEOR. 21. PROPOS. 24.

A line commensurable with a medial line is itself medial.

Let B be a straight line commensurable with the medial line A, whether in length and in square or in square only. I say that B too is medial. For let a rational line CD be assigned, [Margin a: 45.primi — I.45] to which a rectangle DE equal to the square on the medial line A is applied. Since, then, the medial area DE applied to the rational line CD produces CE as its breadth, [Margin b: 23.dec — X.23] CE will be rational but incommensurable in length with CD itself. Again, to the rational line CD [Margin c: 45.prim — I.45] let a rectangle DF equal to the square on B be applied. And since the straight lines A and B are assumed commensurable, their squares — that is, the rectangles DE and DF equal to them — will also be commensurable. But [Margin d: 1.sextri — VI.1] DE is to DF as the straight line EC is to the straight line CF. [Margin e: 10.dec — X.10] Therefore EC and CF are commensurable in length. But EC was shown to be rational and incommensurable in length with CD; [Margin f: 14.dec — X.14] therefore CF too is incommensurable in length with that same CD. Since, then, CF is commensurable with the assigned rational line CD (for since EC and CF were shown to be commensurable in length, and EC is commensurable with CD at least in square, because it is rational, CF too will be commensurable with that same CD in square, by what we wrote in the scholium to Proposition 12 of this book), CD and CF will be rational lines commensurable in square only. [Margin g: 22.dec — X.22] And accordingly the line B, whose square is the rectangle DF contained by the rational lines CD and CF, commensurable in square only, is medial. Therefore a line commensurable with a medial line is medial. Which was to be shown.

Diagram. Two short line segments above a rectangle divided vertically into two parts.

- A (upper segment): the medial line.
- B (segment just below A): the line commensurable with A.
- Rectangle on base EF: E (bottom-left), C (bottom, at the vertical division), F (bottom-right), D (top, above C at the division); the outer top corners are unlabeled. The left portion (on base EC) is the rectangle DE, equal to the square on A; the right portion (on base CF) is the rectangle DF, equal to the square on B.

COROLLARIVM.

From this it is clear that an area commensurable with a medial area is medial. For after it was demonstrated that DF is commensurable with the medial area DE, it was at once shown from this that DF is likewise medial — namely, contained by the rational lines CD and CF, commensurable in square only. And the same reasoning holds in the remaining cases. This, however, can also be demonstrated in the following way.

Let the area DF be commensurable with the medial area DE. I say that DF too is medial. For let A, a medial line, be the side of the area DE (for since DE is medial, a straight line — the one called medial — can be its side, as we set out in the scholium to Proposition 22 of this book); and let B be the side of DF. Since, then, DE and DF are commensurable, their squares

on A and on B, equal to them, will also be commensurable. Therefore the straight lines A and B are commensurable at least in square; and hence, A being medial, B too will be medial commensurable with it, as was shown in this theorem. Therefore DF too will be medial. For every area whose side is a medial line is called medial, as we taught in the scholium to Proposition 22 of this book.

I. LEMMA.

[Enunciation:] Just as was said about rational lines in Lemma 1 to Proposition 19 of this book, so here too we shall speak of medial lines. Namely, that a straight line commensurable in length with a medial line is called medial, and commensurable with it not only in length but also in square. For universally, lines commensurable in length are also commensurable in square. But if some straight line is commensurable in square with a medial line — provided it is so in length as well — it too will be called medial, and commensurable with it in length and in square. But if, on the other hand, some line commensurable with a medial line in square is incommensurable in length, it too will be called medial, commensurable with it in square only.

II. LEMMA.

[Enunciation:] To find two medial lines commensurable in length; likewise two commensurable in square only.

Diagram. Three horizontal line segments, one above another.

- A (topmost segment): the given medial line.

- B (middle segment): a line commensurable with A in length.
- C (lowest segment): a line commensurable with A in square only.

Let A be some medial line, and suppose that two straight lines B and C are found commensurable with it — the one, B, in length, and the other, C, in square only. [Margin a: 24.dec — X.24] Then each of B and C, being commensurable with the medial line A, will be medial. Since, then, A and B are commensurable in length, the lines found, A and B, will be medial lines commensurable in length; and A and C will be medial lines commensurable in square only. Which was what was proposed.

SCHOLIVM.

Although every straight line commensurable with a medial line is medial, nevertheless not every medial line is commensurable with every medial line; for two medial lines can be given that are altogether incommensurable — that is, in length and in square — as will appear from Proposition 36 of this book. There we shall also teach by what method two medial lines incommensurable in length and in square are to be found.

THEOR. 22. PROPOS. 25.

[Margin, alongside the heading: xxiii. / xxiii.]

The rectangle contained by medial straight lines commensurable in length is medial.

Let the rectangle AD be contained by the medial lines AC and CD, commensurable in length. I say that AD is medial. On CD, a medial line, let the square BD be described, which will be medial. [Margin a: 1.sexti — VI.1] And since AC is to CB as AD is to DB, and since AC and CB — that is, AC and CD — are commensurable in length, AD and DB will be commensurable. Hence the area AD, being commensurable with the medial area DB, is medial, by the corollary to the preceding proposition. Therefore what is contained by medial lines commensurable in length, etc. Which was to be shown.

Diagram. A rectangle on base AB, divided vertically at C, with a square on the right-hand part.

- A (bottom-left), C (bottom, at the vertical division), B (bottom-right), D (top, above C); the outer top corners are unlabeled.

- The left portion (on base AC) is the rectangle AD; the right portion (on base CB) is the square BD described on CD.

THEOR. 23. PROPOS. 26.

[Margin, alongside the heading: xxv. / xxiii[i?].]

The rectangle contained by medial straight lines commensurable in square only is either rational or medial.

Let the rectangle AC be contained by the medial lines AB and BC, commensurable in square only. I say that AC is either rational or medial. On AB and BC let the squares AD and CE be described, which will be medial (as we set out in the scholium to Proposition 22 of this book), since the straight lines AB and BC are assumed medial. Let a rational line FG be assigned, [Margin a: 45.primi — I.45] to which is applied the rectangle FH equal to the square AD described on AB; and to HI the rectangle IK equal to the rectangle AC; and finally to KL the rectangle LM equal to the square CE described on BC. And the whole FM will be a single rectangle, as was shown in Proposition 45 of Book 1. Now since AD and CE are medial, FH and LM, equal to them, will also be medial; and when these are applied to the rational lines FG, KL,

(FG and KL — for [Margin b: 34.prim — I.34] KL is equal to the rational line FG, because FK is a parallelogram, and is therefore rational) and produce as breadths GH and KM, [Margin c: 23.dec — X.23] the straight lines GH and KM will be rational but incommensurable in length with FG (or KL). And since the straight lines AB and BC are commensurable in square with one another, their squares AD and CE will be commensurable, and hence also the rectangles FH and LM equal to them; [Margin d: 1.sexti — VI.1] and FH is to LM as the straight line GH is to KM. [Margin e: 10.dec — X.10] Therefore GH and KM are commensurable in length with one another. So GH and KM, shown to be rational, are commensurable in length with one another, but commensurable with the rational line FG in square only, since they were shown to be incommensurable with it in length. [Margin f: 20.dec — X.20] And for this reason the rectangle contained by GH and KM is rational. And since DB is to BC as AB is to BE (because DB and BC are equal to AB and BE respectively, each to each), [Margin g: 1.sexti — VI.1] and since DB is to BC as AD is to AC, and AB is to BE as AC is to CE, it will also follow that AD is to AC as AC is to CE; and hence AD, AC, CE are proportional. Therefore FH, HL, LM, equal to them, will also be proportional. [Margin h: 1.sexti — VI.1] But the straight lines GH, HK, KM have the same ratios as the rectangles FH, HL, LM. Therefore the straight lines GH, HK, KM too are proportional;

[Margin i: 17.sexiti — VI.17] and consequently the rectangle contained by GH and KM is equal to the square on HK. But the rectangle contained by GH and KM was shown to be rational. Therefore the square on HK too is rational; and accordingly the straight line HK is [Margin k: 6.def — X, Def. 6] commensurable with the assigned rational line — that is, with HI itself — either in length and in square, or in square only. And if indeed HK is commensurable in length with HI, [Margin l: 20.dec — X.20] the rectangle HL, contained by the rational lines HI and HK commensurable in length — that is, AC, which is equal to it — will be rational. But if HK is commensurable with HI in square only, [Margin m: 22.dec — X.22] the rectangle HL contained by the rational lines HI and HK commensurable in square only — that is, AC, which is equal to it — will be medial. Therefore AC is a rectangle contained by the medial lines AB and BC commensurable in square only, and is either rational or medial. And so what is contained by medial lines commensurable in square only, etc. Which was to be shown.

Diagram. A cross-shaped square figure representing the mean-proportional construction on AB and BC.

- E (top), A (bottom): endpoints of the vertical axis through the center B.
- D (left), C (right): endpoints of the horizontal axis through the center B.
- B (center): the point of division on the base line, where the squares AD (on AB) and CE (on BC) meet; the rectangle AC is contained by AB and BC.

Diagram. A long rectangle FM divided vertically into three rectangles.

- F (top-left), I (top, first division), L (top, second division), M (top-right).
- G (bottom-left), H (bottom, first division), K (bottom, second division), M (bottom-right).
- The three parts are: FH (leftmost, on FG–IH), IK (middle, on IH–LK, equal to the rectangle AC), and LM (rightmost, on LK–M). The whole is applied to the rational lines FG and KL.

SCHOLIVM.

More easily than by Proposition 45 of Book 1, we shall apply to HI a rectangle equal to AC itself, [Margin n: 12.sexiti — VI.12] if a fourth proportional to the three straight lines HI, AB, BC is taken as the side HK. [Margin o: 16.sexiti — VI.16] For the rectangle contained by the extremes HI and HK will be equal to the rectangle contained by the means AB and BC.

We shall use this same technique in what follows, whenever a rectangle equal to another rectangle is to be applied to some straight line.

Now since in this theorem it is demonstrated that the rectangle contained by two medial lines commensurable in square only is either rational or medial, Euclid will teach, in Proposition 28, by what method two medial lines commensurable in square only are to be found that contain a rational area; and in Proposition 29 he will seek two medial lines commensurable in square only that contain a medial area.

And so we have from these results: [Margin p: 20.dec — X.20] that the rectangle contained by two rational lines commensurable in length is rational; [Margin q: 22.dec — X.22] but the rectangle contained by two rational lines commensurable in square only is irrational, and is called medial, and the line whose square it is is called medial. Again, from what has been demonstrated it is established [Margin r: 25.dec — X.25] that the rectangle contained by two medial lines commensurable in length is medial; [Margin s: 26.dec — X.26] but the rectangle contained by two medial lines commensurable in square only is either rational or medial.

But if anyone should ask what kind of rectangle that is which is contained by two medial lines incommensurable in length and in square, we answer that it is neither rational nor medial, but constitutes a certain third kind — namely, that it is equal to a rectangle contained by a rational line and an irrational line, the latter being called medial.

For let the rectangle AC be contained by two medial lines AB and BC incommensurable in length and in square. I say that AC is neither rational nor medial, etc. For, the same construction being made as in the theorem, we shall show similarly that the straight lines GH and KM are rational and incommensurable in length with FG. And since the straight lines AB and BC are assumed incommensurable in length and in square, their squares AD and CE — and hence the rectangles FH and LM equal to them — will be incommensurable. [Margin t: 1.sexti — VI.1] And FH is to LM as the straight line GH is to the straight line KM. [Margin u: 10.dec — X.10] Therefore the straight lines GH and KM are incommensurable in length with one another. So GH and KM, shown to be rational, are commensurable in square only with one another; [Margin x: 22.dec — X.22] and accordingly the rectangle contained by GH and KM is irrational — the kind that is called medial — and the straight line whose square it is is irrational, the kind called medial. [Margin y: 17.sexti — VI.17] Now HK is the side of the rectangle contained by GH and KM (for, as we showed before, the three lines GH, HK, KM are proportional). Therefore HK is irrational and medial. Hence IK is not rational; for if it were rational, [Margin z: 21.dec — X.21] it would, when

applied to the rational line HI, make its breadth HK rational and commensurable in length with HI. Which is absurd, for HK was shown to be irrational and medial. In the same way IK is not medial either; for if it were medial, [Margin a: 23.dec — X.23] it would, when applied to the rational line HI, make its breadth HK rational and incommensurable in length with HI — which is absurd, for HK was shown to be irrational and medial. And so, since IK is neither rational nor medial, necessarily AC, which is equal to it, will be neither rational nor medial, but will constitute a certain third kind; namely, it will be equal to IK, which is contained by a rational line and a medial line, since HI is rational and HK was shown to be medial. From all this it follows that the straight line whose square is the area contained by two medial lines incommensurable in length and in square — such as AB and BC are assumed to be — can also be the side of a rectangle contained by a rational line and an irrational line called medial. Which was what was proposed.

THEOR. 24. PROPOS. 27.

[Margin: xxvi. / xxii.[?] — divergent lowercase-roman prop-counter (Theon vs. Clavius offset)]

A medial does not exceed a medial by a rational.

Let the medial AB exceed the medial AC by the rectangle DB. I say that DB is not rational. For suppose, if it be possible, that DB is rational. Then, a rational line EF being set out, let the rectangle EG, equal to the medial AB, be applied to it [Margin: a. Elements I.45], and let the rectangle EH be applied equal to the medial AC, so that the remainder HI is equal to the rational DB. Now EG and EH will be medial, being equal to the medial areas AB and AC, while HI will be rational, being equal to the rational DB. Since, then, the medial areas EG and EH have been applied to the rational line EF, the lines FG and FH will be rational and incommensurable in length with EF [Margin: b. Elements X.23].

Again, since the rational area HI has been applied to the rational line HK — for the line HK is equal to the rational EF [Margin: c. Elements I.34] — the line HG will be rational and commensurable in length with EF [Margin: d. Elements X.21]. Therefore, since HG and EF are commensurable in length, while EF is incommensurable in length with FH, as was shown, HG too will be incommensurable in length with that same FH [Margin: e. Elements X.14]. But as FH is to HG, so is the square on FH to the rectangle contained by FH and HG, by the third lemma of Proposition 19 of this book. Therefore the square on FH is

incommensurable with the rectangle contained by FH and HG [Margin: f. Elements X.10].

But the square on HG is commensurable with the square on FH — since both are described on the rational lines FH, HG [Margin: g. Elements X.16] — and so the two squares on FH and HG together are also commensurable with the square on FH. And the rectangle contained by FH and HG is commensurable with twice the rectangle contained by FH and HG, because the latter is double the former. Therefore, by what we showed in the scholium to Proposition 14 of this book, the two squares on FH and HG together are also incommensurable with twice the rectangle contained by FH and HG [Margin: h. Elements X.17]. Hence the sum of the squares on the lines FH, HG together with twice the rectangle contained by FH and HG is incommensurable with the sum of the squares on the lines FH and HG [Margin: i. Elements II.4].

But the sum of the squares on FH and HG together with twice the rectangle contained by FH and HG is equal to the square on FG. Therefore the square on FG is also incommensurable with the sum of the squares on the lines FH and HG. Now this sum is rational, by the fourth lemma of Proposition 19 of this book, in that it was shown to be commensurable with the rational square on FH. Since, then, the square on FG is incommensurable with this sum, which is rational, the square on FG will be irrational [Margin: k. Elements X.10], and therefore the line FG too will be irrational [Margin: l. Elements X.11]. But this is absurd, since FG was shown to be rational and incommensurable in length with EF. Therefore DB, by which the medial AB exceeds the medial AC, is not rational. For which reason a medial does not exceed a medial by a rational. Which was to be shown.

Diagram. The upper figure is a rectangle divided by a vertical dashed line, illustrating the applied rectangles on the rational line EF and the excess DB. Labelled points read off the scan under magnification:

- I (upper-right corner)
- F (lower-left corner)
- H (lower edge, mid)
- G (lower-right corner)

SCHOLIVM.

From what has been said we will also demonstrate the following:

A rational exceeds a rational by a rational.

For let the rational AB exceed the rational AC by the space DB. I say that DB too is rational. Since AB and AC are rational, they will be commensurable with the square on the rational line set out [Margin: m. Elements X, def. 9], and so they are commensurable with each other as well [Margin: n. Elements X.12]. Therefore, since the whole AB — which is compounded of AC and DB — is commensurable with AC, the same AB will also be commensurable with the remainder DB, by the corollary to Proposition 16 of this book. But AB is rational. Therefore DB too, by the fourth lemma of Proposition 19 of this book, is rational. Which was what was proposed.

Diagram. A rectangle divided by a vertical dashed line, representing the whole AB compounded of AC and the excess DB. Labelled points:

- C (top edge, at the dividing line)
- B (top-right corner)
- A (bottom-left corner)
- D (bottom edge, at the dividing line)

PROBL. 4. PROPOS. 28.

[Margin: xxvii. / o.]

To find two medial lines, commensurable in square only, which contain a rational rectangle.

Let two rational lines A, B, commensurable in square only, be set out — by lemma 2 of Proposition 21 of this book — [Margin: a. Elements VI.13] and let a mean proportional C be taken between them [Margin: b. Elements VI.12], and let it be contrived that as A is to B, so is C to D. I say that C, D are two medial lines commensurable in square only which contain a rational rectangle. For since A, B

are supposed rational and commensurable in square only, the rectangle contained by them will be irrational, which is called medial [Margin: c. Elements X.22]; and therefore, since the line C is capable of it [i.e. the square on C equals that rectangle] [Margin: d. Elements VI.17], C will be medial. And since as A is to B, so is C to D, and A, B are commensurable in square only, C and D too will be commensurable in square only, as we showed in the scholium to Proposition 10 of this book [Margin: e. Elements X.24]. Therefore D is medial and commensurable in square with the medial C. Hence there have been found two medial lines C, D commensurable in square only.

I say now that they contain a rational rectangle. For since as A is to B, so is C to D, then, alternately, as A is to C, so is B to D. But as A is to C, so is C to B; therefore also, as C is to B, so is B to D, and so B is a mean proportional between C and D [Margin: f. Elements VI.17]. Therefore the rectangle contained by C, D will [equal the square on B]. But the square on B, a rational line, is rational. Therefore the rectangle contained by C, D is also rational. We have therefore found two medial lines C, D, commensurable in square only, which contain a rational rectangle. Which was to be done.

Diagram. Four line segments drawn one above another, representing the four lines of the construction (A and B the two rationals commensurable in square only, C the mean proportional, D the fourth proportional). Labels, top to bottom:

- A (top segment)
- C (second segment, drawn with a dashed portion)
- B (third segment)
- D (bottom segment)

PROBL. 5. PROPOS. 29.

[Margin: xxviii. / o.]

To find two medial lines, commensurable in square only, which contain a medial rectangle.

Let three rational lines A, B, C, commensurable in square only, be set out — by what we demonstrated in the scholium to Proposition 21 of this book — [Margin: a. Elements VI.13] and let a mean proportional D be found between A and B [Margin: b. Elements VI.12]. Then let it be contrived that as B is to C, so is D to E. I say that D, E are two medial lines commensurable in square only which contain a medial rectangle. For since A, B are rational and commensurable in square only, the rectangle contained by A, B — and therefore also the square on D, which is

equal to it [Margin: c. Elements VI.17] — will be irrational, which is called medial [Margin: d. Elements X.22]; and the line D itself is medial. And since as B is to C, so is D to E, while B, C are rational and commensurable in square only, D and E too will be commensurable in square only, as was demonstrated in the scholium to Proposition 10 of this book. Since, then, D is medial, E too will be commensurable in square with it, and medial [Margin: e. Elements X.24]; and therefore D, E are two medial lines commensurable in square only.

I say now that they contain a medial rectangle. For since as B is to C, so is D to E, then, alternately, as B is to D, so is C to E. But as B is to D, so is D to A; therefore also, as D is to A, so is C to E. Therefore the rectangle contained by D, E is equal to that contained by A, C [Margin: f. Elements VI.16]. But the rectangle contained by A, C — rational lines commensurable in square only — is irrational and medial [Margin: g. Elements X.22]. Therefore the rectangle contained by D, E is also medial. We have therefore found two medial lines D, E, commensurable in square only, which contain a medial rectangle. Which was to be done.

Diagram. Five line segments drawn one above another, representing the five lines of the construction. Labels, top to bottom:

- A (top segment)
- D (second segment)
- B (third segment)
- C (fourth segment)
- E (bottom segment)

SCHOLIUM. I.

In what follows we need this problem:

To find two similar plane numbers.

Let any four proportional numbers A, B, C, D be taken, such that as A is to C, so is B to D. Let A and B, multiplying one another, make E; and likewise let C and D, multiplying one another, make F. Then E and F will be similar plane numbers, since their sides are proportional, as is clear from the construction.

A,	6.	C,	12.
B,	4.	D,	8.
E,	24.	F,	96.

Now since it was shown in Book 9 [Margin: h. Elements IX.28 & 29] that if an odd number or an even number multiply an even number, an even number is produced, but an odd number if an odd multiply an odd, it is clear in what manner two similar plane numbers can be found, of which each is even, or each odd, or one even and the other odd. For if the sides taken are even numbers, their plane numbers too will be even; but if the numbers are odd, their plane numbers too will be odd. And if the sides of the one are odd numbers and those of the other even, the plane number of the former will be odd, that of the latter even. Similarly, the plane numbers will be even if each has one side an even number and the other an odd number, and so on.

LEMMA I.

To find two square numbers such that the sum compounded of them is also a square.

Let two similar plane numbers AB and C be found, by what was said in the preceding scholium [Margin: i. Elements IX.24 & 26], each of which is either even or odd. And since, whether an even be taken from an even or an odd from an odd, the remainder is even, then, if BD — equal to C itself — be taken away from AB, the remainder AD will be even. Let AD be bisected at E. I say that the number produced from AB by BD — which is indeed a square [Margin: k. Elements IX.1] — compounded with the square of the number ED, makes a square. For since the number AD is bisected at E and DB is added to it, then, by the 6th theorem of those which we demonstrated at Proposition 14 of Book 9, the number produced from AB by BD, together with the square of the number DE, will be equal to the square of the number EB. Therefore the two squares — namely that produced from AB by BD, and the square of the number DE — compounded make a square, namely the one generated from BE. Which was what was proposed.

Diagram. A number-line figure: an upper line marked off in units by dots with points A, E, D, B labelled along it, and a shorter lower line for the number C. As drawn:

- Upper line: A E D B (A at left end, E and D interior division points, B at right end)
- Lower line: C (the number C)

COROLLARIUM.

From these things it is clear that, when AB and C are similar, there have been found by the same method two square numbers of the numbers BE, ED, whose

difference — namely the number produced from AB by BD — is also a square number.

But if the numbers AB and C are taken not similar, yet each even or each odd, there will be found in the same way two squares of the numbers BE, ED, whose difference — namely the number produced from AB, BD — is not a square [Margin: I. Elements IX.2]. For if it were a square, the numbers AB, BD — that is, AB and C — would be similar plane numbers. But that is absurd, for they are supposed not similar.

SCHOLIVM. II.

Therefore, if we are bidden to find two square numbers whose difference is likewise a square number, we shall take, as before, two similar plane numbers, of which each is either even or odd, namely AB and C, and we shall carry out the rest as was said in the immediately preceding lemma. For the square numbers described on BE, ED are those which we seek. For the square on BE exceeds the square on ED by the number produced from AB by BD, which is also a square.

Diagram. A number-line figure. As drawn:

- Upper line: A..... E..... D..... B
- Lower line: c..... (the number C)

But if two squares are to be found whose difference is not a square, then two plane numbers AB and C, not similar, each of which is either even or odd, must be taken, and the rest carried out as before. For in the same way we shall show that the square on BE is equal to the square on DE together with that which is produced from AB by BD. Hence the difference of the squares on BE, ED is the number produced from AB by BD, which, since it is not a square — for if it were a square, AB, BD would be similar plane numbers, which is not supposed — the proposition stands established.

Diagram. A second number-line figure, more compact than the first. As drawn:

- Upper line: A... E... D..... B
- Lower line: c..... (the number C)

This latter case we shall carry out more easily if we divide any square number into two numbers, of which one is a square and the other not. Thus, if the square 36 be divided into the square 16 and the non-square 20, the square 36 will exceed the square 16 by the non-square number 20. Likewise, if the same square 36 be

divided into the square 25 and the non-square 11, the square 36 will exceed the square 25 by the non-square number 11. And so with the rest.

LEMMA II.

To find two square numbers such that the sum compounded of them is not a square.

Let there be two similar plane numbers AB and C , even or odd, as in the preceding lemma, and let the same construction be made, so that again the square produced from the multiplication of the similar numbers AB , DB by one another, together with the square on DE , is equal to the square on BE . Then let the unit EF be taken away from DE . The square on DF will then be less than the square on DE , since the side DF is also less than the side DE . I say that the square numbers, of which one is produced from AB by BD and the other from DF by itself, compounded do not make a square number. For if the sum compounded of them is a square, it will be either greater than the square on BE , or equal to it, or less; and that this cannot be, we shall demonstrate in the following manner.

Let it first be greater than the square on BE , and therefore its side greater than the side BE . Then its side will be either equal to the number BE or greater. (For it will not be less, since between the numbers BE , BF , which differ from one another by a unit alone, there is no intermediate number, unless the unit itself be cut; and the said side would be intermediate between them if it were supposed greater than BF but less than BE .) If it be said equal — so that the square number compounded of the square produced from AB by BD and the square of the number DF is equal to the square on BE — then, since to the same square on BE there was shown, in the preceding lemma, to be equal the number produced from AB by BD together with the square on DE , it will be that the number produced from AB by BD together with the square on DE [is equal to that composite]. The common part being taken away, namely the number produced from AB by BD , the remaining square on DF will be equal to the remaining square on DE ; and therefore the side DF equal to the side DE — a part to the whole. Which is absurd. Therefore the side of the square compounded of the squares, of which one is produced from AB by BD and the other from DF by itself, is not equal to the number BE .

Diagram. A number-line figure (reprinted twice on the page), with the additional points H , I , F , G marked on the upper line. As drawn:

- Upper line: $A \dots H \dots I \dots E \dots F \dots G \dots D \dots B$ (A at left end; H , I , E , F , G interior division points; D and B toward the right)
- Lower line: $C \dots$ (the number C)

Let it be, then, if it be possible, that its side is equal to the number BI, which is greater than BE, so that the square on BI is equal to that composite square. Since, then, the square on BI, with the greater side, is greater than the square on BE, with the lesser side, the composite of the squares — of which one is produced from AB by BD and the other from DF by itself — will also (since this composite is supposed equal to the square on BI) be greater than the square on BE. But equal to the square on BE was shown, in the preceding lemma, the number produced from AB by BD together with the square on DE. The common part being taken away, namely that produced from AB by BD, the remaining square on DF will be greater than the remaining square on DE; and consequently the side DF greater than the side DE — a part greater than the whole. Which is absurd. Therefore the side of the square compounded of the squares, of which one is produced from AB by BD and the other from DF by itself, is not greater than the side BE. But neither equal nor less has it been shown. Therefore that composite square is not greater than the square on BF.

(Conclusion of Lemma II — the demonstration continued from the preceding page.)

Now suppose, if it be possible, that the number produced by AB times BD, together with the square on DF, is equal to the square on BF; and let a number AH be taken, double the unit EF. Since the whole AD is double the whole ED (for AD has been bisected at E), and the part removed, AH, is double the part removed, the unit EF, the remainder HD too will be double the remainder FD — as we showed in connection with Proposition 7 of Book 7 — and therefore HD is bisected at F. Hence, by the 6th of the theorems we demonstrated in connection with Proposition 14 of Book 9, the number produced by HB times BD, together with the square on DF, will be equal to the square on BF. But the number produced by AB times BD together with the square on DF was assumed equal to that same square on BF. Therefore the number from HB times BD together with the square on DF is equal to the number from AB times BD together with the square on DF; and when the common square on DF is subtracted, the number from HB times BD is left equal to the number from AB times BD. Now since HB and AB, multiplying the same BD, produce equal numbers, and since [Margin: a. Elements VII.18] multipliers stand in the same ratio as their products, HB will be equal to AB — a part to the whole. This is absurd. Therefore the number from AB times BD together with the square on DF is not equal to the square on BF.

Finally, suppose, if it be possible, that the number from AB times BD together with the square on DF is less than the square on BF, and consequently that its side too is less than the side BF — let this be BG — so that the number from AB times BD together with the square on DF is equal to the square on BG. Let AI be

taken, double of EG. Since the whole AD is double the whole ED [the ambiguous: printed form may read "FD"], and the part removed, AI, is double the part removed, EG, again the remainder ID will be double the remainder GD; and therefore ID is bisected at G. Hence, by the same 6th of the theorems demonstrated in connection with Proposition 14 of Book 9, the number from IB times BD together with the square on DG will be equal to the square on BG. But the number from AB times BD together with the square on DF was assumed equal to that same square on BG. Therefore the number from IB times BD together with the square on DG is equal to the number from AB times BD together with the square on DF.

Diagram. A number-line schematic accompanying the lemma. A single straight row of points is marked, in order, A · · H · · I · E · F · G · · · D · · · · · B, with a second point C set below at the far left (C · · · · ·). It displays the divisions used in the demonstration: E bisects AD; H, I, F, G are the intermediate division points; B lies at the right; C marks the separate number placed below.

- A: left end of the divided segment
- H, I: division points near the left
- E: midpoint of AD
- F, G: further division points
- D: right end of the divided segment
- B: point at the far right
- C: separate point set below the left end

So when the squares on DG and DF are subtracted — of which the square on DG is the smaller — there remains the number from IB times BD greater than the number from AB times BD: a part greater than the whole. This is absurd.

Therefore the number from AB times BD together with the square on DF is not less than the square on BF. But it was shown to be neither greater nor equal.

Therefore the number from AB times BD together with the square on DF is not a square. Which was the proposition.

SCHOLIUM III.

From this we shall easily find two numbers such that the number compounded of them has to neither of them the ratio that a square has to a square. For if, by the preceding lemma, two square numbers are found whose sum is not a square, this non-square sum will have to neither of those squares the ratio of a square to a square.

We shall obtain the same result if we divide any square number into two non-square parts. For then the whole square will have to neither of the parts into which it is divided the ratio of a square to a square.

PROBL. 6. PROPOS. 30. [Margin: xxix. xvij.]

To find two rational straight lines commensurable in square only, such that the greater is more powerful than the less by the square on a straight line commensurable with it in length.

Let a rational straight line AB be set out; and, by the method we handed down in Scholium 2 of Proposition 29 of this book (the preceding one), let two square numbers CD, CE be found whose excess DE is not a square. Then, by the corollary to Proposition 6 of this book, let it be contrived that as the number CD is to the number DE, so is the square on AB to another square — namely to the square on AF; and let AF be fitted into the semicircle ABF described on the diameter AB; and finally let the straight line FB be joined.

Now since the angle F is right, being in a semicircle, [Margin: a. Elements III.31] the square on AB will be equal to the two squares on AF and FB together; [Margin: b. Elements I.47] that is, the straight line AB is more powerful than AF by the square on the straight line FB. And since the square on AB is to the square on AF as the number CD is to the number DE, [Margin: c. Elements X.6] the squares on AB and AF will be commensurable. And so, since the square on AB is rational — being described on the rational line AB — the square on AF will also be rational, and consequently the straight line AF that describes it is rational as well. Therefore AB and AF are rational, and hence commensurable at least in square.

But the square on AB does not have to the square on AF the ratio that a square number has to a square number — for the square number CD does not have to the non-square DE the ratio of a square to a square (otherwise DE too would be a square, [Margin: d. Elements VIII.24] as is demonstrated in the arithmetical books, which is not assumed). [Margin: e. Elements X.9] Therefore the straight lines AB and AF are incommensurable in length. Yet they are commensurable in square, as was shown. Therefore AB and AF are rational lines commensurable in square only.

Now since CD is to DE as the square on AB is to the square on AF, then by conversion of the ratio the square number CD will be to the square number CE as the square on AB is to the square on FB. For just as CD exceeds DE by the square CE, so too the square on AB exceeds the square on AF by the square on FB.

[Margin: f. Elements X.9] Therefore the straight lines AB and FB are commensurable in length. We have therefore found two rational straight lines AB and AF, commensurable in square only, such that the greater AB is more powerful than the less AF by the square on the line FB, which is commensurable with it in length. Which was to be done.

Diagram. A semicircle described on the diameter AB (A at the lower left, B at the lower right), with F a point on the arc at the top. The chords AF and FB are drawn, forming the right triangle AFB inscribed in the semicircle (the right angle at F). A small tick I is marked on the diameter AB. Below the diameter runs a separate dotted number-line: C at the left, E about the middle, D toward the right (C ····· E ····· D), representing the number CD divided at E.

- A: left end of the diameter
- B: right end of the diameter
- F: point on the semicircular arc; vertex of the right angle
- I: point marked on the diameter AB
- C, E, D: points of the number-line beneath (CD divided at E)

PROBL. 7. PROPOS. 31. [Margin: xxx. xviiij.]

To find two rational straight lines commensurable in square only, such that the greater is more powerful than the less by the square on a straight line incommensurable with it in length.

Let a rational straight line AB be set out; and by Lemma 2 of Proposition 29 of this book let two square numbers CE, ED be found such that the number CD compounded of them is not a square — or else let some square number CD be divided into two non-square numbers CE, ED. For whichever of these is done, the whole CD will have to neither CE nor ED the ratio of a square to a square. Otherwise, by the former method the whole CD would itself be a square, while by the latter each of CE and ED would be a square as well, [Margin: a. Elements VIII.24] as has been shown in the arithmetical books — which is not assumed.

Then, by the corollary to Proposition 6 of this book, let it be contrived that as CD is to DE, so is the square on AB to another square, namely to the square on AF; and let AF be fitted into the semicircle AFB described on AB; and finally let the straight line FB be joined. Then, as in the preceding proposition, AB will be more powerful than AF by the square on the straight line FB, and AB, AF will be rational lines commensurable in square only — for the demonstration here is the same as in the preceding proposition.

Now again, as before, by conversion of the ratio, as CD is to CE, so is the square on AB to the square on FB. But CD does not have to CE the ratio of a square to a square; therefore the square on AB will not have to the square on FB the ratio that a square number has to a square number either. [Margin: b. Elements X.9] Hence the straight lines AB and FB are incommensurable in length. We have therefore found two rational lines AB, AF commensurable in square only, such that the greater AB is more powerful than the less AF by the square on the line FB, which is incommensurable with it in length. Which was to be done.

Diagram. A semicircle described on the diameter AB (A at the lower left, B at the lower right), with F on the arc; the chords AF and FB form the inscribed right triangle AFB (right angle at F), and a tick I is marked on AB. Beneath the diameter is a divided number-line carrying values: C —144— E —16— D, with the whole segment shown as C —160— D (so CE = 144, ED = 16, CD = 160); a dotted copy of the line (C ····· E ··· D) is drawn below it.

- A: left end of the diameter
- B: right end of the diameter
- F: point on the arc; right-angle vertex
- I: point marked on AB
- C, E, D: number-line points; CE = 144, ED = 16, whole CD = 160

LEMMA A.

If there are two unequal straight lines, then as the greater is to the less, so is the rectangle contained by them to the square on the less.

Let AB, BC be two unequal straight lines set in a straight line, of which AB is the greater. I say that as AB is to BC, so is the rectangle under AB, BC to the square on BC. For on BC let the square BD be described, and let the rectangle AD be completed. Then the rectangle AE will be that contained by AB, BC, since EB is equal to BC; [Margin: c. Elements VI.1] and it is evident that as AB is to BC, so is AE to BD.

In the same way, as the less is to the greater, so will the rectangle contained by them be to the square on the greater, as is clear in the second figure, in which AB is less than BC.

Diagram. Two rectangles illustrating the lemma.

In the first (upper) figure: a rectangle standing on the base C—B—A (C at the left, B in the middle, A at the right) with top side D—E—(unlabelled corner above A).

The vertical line BE divides it. The left part, C-B-E-D, is the square described on BC (labelled by the diagonal corners as square BD); the right part is the rectangle AE contained by AB and BC (since EB = BC). The whole rectangle is AD.

- Upper figure — bottom: C (left), B (middle), A (right); top: D (above C), E (above B)

In the second (lower) figure: the same construction drawn for the case where AB is less than BC — base C—B—A, top D—E—(corner), with the vertical division at BE.

- Lower figure — bottom: C (left), B (middle), A (right); top: D (above C), E (above B)

PROBL. 8. PROPOS. 32. [Margin: xxxj. xxiv. xxv.]

To find two medial straight lines commensurable in square only, containing a rational rectangle, such that the greater is more powerful than the less by the square on a straight line commensurable with it in length.

[Margin: a. Elements X.30] Let two rational lines A, B be found, commensurable in square only, such that the greater A is more powerful than the less B by the square on a line commensurable with it in length; let C be the mean proportional between A and B; and let it be contrived that as A is to B, so is C to D. Since A, B are rational lines commensurable in square only, [Margin: b. Elements X.22] the rectangle under A, B will be irrational, and the straight line C whose square equals it will be a medial line. And since A is to B as C is to D, and A, B are commensurable in square only, C and D too will be commensurable in square only, as we showed in the scholium to Proposition 10 of this book. [Margin: c. Elements X.24] Therefore D, being commensurable with the medial C, is itself also a medial. So two medial lines C, D commensurable in square only have been found.

I say that they contain a rational rectangle. For since A is to B as C is to D, then alternately A is to C as B is to D; but A is to C as C is to B; therefore also C is to B as B is to D. [Margin: d. Elements VI.17] And on this account the rectangle under C, D will be equal to the square on B. For this reason, since the square on B — B being rational — is rational, the rectangle under C, D, equal to it, will also be rational. Therefore the medials C, D, commensurable in square only, contain a rational rectangle.

Now since A is to B as C is to D, and A is more powerful than B by the square on a line commensurable with it in length, by construction, [Margin: e. Elements X.15] C too will be more powerful than D by the square on a line commensurable with it in length. We have therefore found two medial lines C, D commensurable in square only, containing a rational rectangle, such that the greater C is more powerful than the less D by the square on a straight line commensurable with it in length. Which was to be done.

But if A, B are found to be rational lines commensurable in square only such that A is more powerful than B by the square on a line incommensurable with it in length, and the rest is done as before, we shall show in the same way that two medial lines have been

Diagram. Four vertical straight lines of differing lengths standing side by side, labelled (left to right) A, C, B, D — representing the two rationals A, B and the two medials C, D of the construction.

- A: leftmost line (longest)
- C: second line
- B: third line
- D: rightmost line (shortest)

found — two medial lines C, D commensurable in square only, containing a rational rectangle, such that the greater C is more powerful than the less D by the square on a line incommensurable with it in length.

SCHOLIUM.

Others prove this problem by means of the preceding lemma; but we have shown the same thing more briefly and easily without it, as those will readily judge who compare our demonstration with theirs. Indeed, that the lines C, D are medials commensurable in square only which contain a rational rectangle, we show here in just the same way as in Proposition 28 of this book.

LEMMA A.

If there are three straight lines, then as the first is to the third, so is the rectangle contained by the first and second to the rectangle contained by the second and third.

Let AB, BC, CD be three straight lines set in a straight line. I say that as AB is to CD, so is the rectangle under AB, BC to the rectangle under BC, CD. For on BC let the square BCDE be described, and let the rectangle AF be completed. Then AE will be

the rectangle contained by AB, BC, and CF that contained by BC, CD, since BE and CD are each equal to BC. [Margin: a. Elements VI.1] And it is evident that AB is to CD as AE is to CF. Which was the proposition.

Diagram. A long rectangle AF standing on the base A—B—C—D (A at the left, then B, C, D to the right), with the top side E—D—F (E above B, D above C, F above the right end). Two vertical lines divide it into three parts: the left part is the rectangle AE contained by AB, BC; the middle part is the square BCDE described on BC; the right part is the rectangle CF contained by BC, CD.

- Bottom: A (left), B, C, D (right)
- Top: E (above B), D (above C), F (above the right end)

PROBL. 9. PROPOS. 32. [Margin: xxxii. xxvj.]

To find two medial straight lines commensurable in square only, containing a medial rectangle, such that the greater is more powerful than the less by the square on a straight line commensurable with it in length.

Let three rational lines A, B, C be found, commensurable in square only, such that A is more powerful than C by the square on a line commensurable with it in length. (This will be done as follows. [Margin: a. Elements X.30] Two rational lines A, C commensurable in square only having been found, such that A is more powerful than C by the square on a line commensurable with it in length, let another line B be found commensurable in square only with each of A and C, by the method we demonstrated in the scholium to Proposition 21 of this book.) [Margin: b. Elements VI.13] And of A, B let the mean proportional D be taken; [Margin: c. Elements VI.12] and let it be contrived that as D is to B, so is C to E.

Now since, by the preceding lemma, as A is to C, so is the rectangle under A, B to the rectangle under B, C — and since [Margin: d. Elements VI.17] the square on D is equal to the rectangle under A, B, and [Margin: e. Elements VI.16] the rectangle under D, E is equal to the rectangle under B, C, because D, B, C, E are proportional — it will follow that as A is to C, so is the square on D to the rectangle under D, E. But as the square on D is to the rectangle under D, E, so, by Lemma 3 of Proposition 19 of this book, is the straight line D to the straight line E. Therefore as A is to C, so is D to E. But A, C are commensurable in square only; therefore D, E too are commensurable in square only, as we showed in the scholium to Proposition 10 of this book.

[Margin: f. Elements X.22] Now since D, whose square equals the area under A, B — A and B being rationals commensurable in square only — is irrational and medial, [Margin: g. Elements X.24] E too, having been shown commensurable with D, will be medial. So two medial lines D, E commensurable in square only have been found.

And since the rectangle under D, E has been shown equal to the rectangle under B, C — [Margin: h. Elements X.22] which is medial (because B, C are rationals commensurable in square only) — the rectangle under D, E will be medial. Finally, since we showed that A is to C as D is to E, and A is more powerful than C by the square on a line commensurable with it in length, by construction, [Margin: i. Elements X.15] D too will be more powerful than E by the square on a line commensurable with it in length. We have therefore found two medial lines D, E commensurable in square only, containing a medial rectangle, such that the greater D is more powerful than the less E by the square on a straight line commensurable with it in length. Which was to be done.

But if A, B, C are found to be rational lines commensurable in square only such that A is more powerful than C by the square on a line incommensurable with it in length, and the rest is constructed as before, we shall likewise demonstrate that two medial lines D, E commensurable in square only have been found, containing a medial rectangle, such that the greater D is more powerful than the less E by the square on a line incommensurable with it in length. Which can easily be seen from the demonstration given.

Diagram. Five vertical straight lines of differing lengths standing side by side, labelled (left to right) A, D, B, E, C [last label uncertain — possibly G]. They represent the three rationals A, B, C and the two medials D, E of the construction.

- A: leftmost line
- D: second line
- B: third line
- E: fourth line
- C [?]: rightmost line

LEMMA I.

Let ABC be a right triangle having the right angle BAC, and from it let the perpendicular AD be dropped. I say that the rectangle contained by CB, BD is equal to the square on AB; that contained by BC, CD is equal to the square on AC; that contained by BD, DC is equal to the square on AD; and finally that contained by BC, AD is equal to that contained by AB, AC.

Since, by the corollary to Proposition 8 of Book 6, the straight line AB is the mean proportional between CB [printed "CD"; recte CB] and BD, [Margin: k. Elements VI.17] the rectangle under CB, BD will be equal to the square on AB.

By the same reasoning, $\text{rect}(BC, CD) = AC^2$, since by the same corollary AC is the mean proportional between BC and CD.

Again, since by the same corollary AD is the mean proportional between BD and DC, in the same way $\text{rect}(BD, DC) = AD^2$.

Finally, [Margin: l — VI.18] since the triangles ABC and ABD are similar, $BC : AC = AB : AD$. [Margin: m — VI.16] Therefore $\text{rect}(BC, AD) = \text{rect}(AB, AC)$. This can also be shown in the following way. Let the rectangle CE, contained by BC and AD, be completed, and likewise the rectangle AF, contained by AB and AC. [Margin: n — I.41] Since, then, the rectangle CE is double the triangle ABC, and the rectangle AF is likewise double the same triangle, the two rectangles CE and AF are equal to one another. Which was proposed.

Diagram. The compound figure for Lemma I: a right triangle with the right angle at A and the perpendicular AD dropped to the base, together with the two rectangles CE and AF named in the demonstration.

- E (upper left): corner of the rectangle CE erected over the base
- A (top, apex of the right angle BAC): vertex of the triangle
- B (lower left): base endpoint
- D (on the base): foot of the perpendicular AD
- I [?] (on the base, between D and C): a marked point, its role not stated in the text
- C (right, on the base): base endpoint
- F (bottom vertex): far corner of the large rectangle AF, contained by AB and AC

LEMMA II.

If a straight line is cut into two unequal parts, then as the greater part is to the lesser, so is the rectangle contained by the whole and the greater part to the rectangle contained by the whole and the lesser part.

Let the straight line AB be cut, not into equal halves, at C, and let AC be the greater part. I say that as AC is to CB, so is $\text{rect}(AB, AC)$ to $\text{rect}(AB, CB)$. For let the square ABDE of AB be described, and let CF be drawn parallel to AE. Then AF will be the rectangle contained by AB and AC, and CD the rectangle contained by AB

and CB, since AE and CF are equal to AB. [Margin: o — VI.1] Since, therefore, as AC is to CB, so is AF to CD, the proposition is established.

By the same reasoning, as the lesser part BC is to the greater CA, so is BF — contained by AB and BC, the whole and the lesser part — to CE, contained by AB and CA, the whole and the greater part.

Diagram. The square on AB for Lemma II, with CF drawn parallel to the sides.

- E (top left): upper corner of the square ABDE
- F (top, above C): where CF meets the top side
- D (top right): upper corner of the square
- A (bottom left): endpoint of the base
- C (bottom, the point of section): the cut of AB
- B (bottom right): endpoint of the base

LEMMA III.

If there are two unequal straight lines, and the lesser is bisected, then the rectangle contained by them is double the rectangle contained by the greater line and half the lesser.

Let AB, BC be two unequal straight lines forming the right angle ABC, and let the lesser, BC, be bisected at D. I say that $\text{rect}(AB, BC)$ is double $\text{rect}(AB, BD)$. For let the rectangle AC, contained by AB and BC, be completed, and let DE be drawn parallel to AB. Then BE will be the rectangle contained by AB and BD, half the lesser line. [Margin: p — VI.1] Since, therefore, AC is double BE — because the base BC is double the base BD — the proposition is established.

In the same way, if BC, bisected, be the greater line, then the rectangle contained by AB, BC will be double the one contained by AB, the lesser, and BD, half the greater, as appears from the second figure.

Diagram. Two rectangles side by side illustrating the two cases of Lemma III; in each, DE is drawn parallel to AB and D bisects the base.

- Left figure — A (top left), E (top, above D); B (bottom left), D (bottom, midpoint), C (bottom right)
- Right figure — A (top left), E (top, above D); B (bottom left), D (bottom, midpoint), C (bottom right)

PROBL. 10. PROPOS. 34.

[Margin: xxxiii. / xxvii.]

To find two straight lines incommensurable in square which make the sum of their squares rational, but the rectangle contained by them medial.

[Margin: a — X.31] Let two rational lines AB, CD, commensurable in square only, be taken, such that the greater, AB, is more powerful than the lesser, CD, by the square on a line incommensurable with it in length; and let CD be bisected at E. Then, by lemma 2 of proposition 17 of this book, apply to AB a rectangle equal to the square on CE — that is, to the fourth part of the square on CD — deficient by a square figure, and let it be the one contained by AF, FB. Finally, on AB describe the semicircle AGB, erect FG perpendicular to AB, and join the lines AG, GB.

Now since AB is more powerful than CD by the square on a line incommensurable with it in length, and a rectangle contained by AF, FB, equal to the fourth part of the square on CD and deficient by a square figure, has been applied to AB, [Margin: b — X.19] AF will be incommensurable in length with FB. And as AF is to FB, so — by lemma 2 of the preceding proposition — is $\text{rect}(AB,AF)$ to $\text{rect}(AB,FB)$; while $\text{rect}(AB,AF)$ is equal to AG^2 , and $\text{rect}(AB,FB)$ to GB^2 , by lemma 1 of the same preceding proposition, [Margin: c — III.31] because the angle AGB is right, being in the semicircle AGB. Therefore as AF is to FB, so is AG^2 to GB^2 ; and since AF, FB are incommensurable in length, [Margin: d — X.10] the squares AG^2 , GB^2 will be incommensurable. [Margin: e — X def. 4] Therefore the lines AG, GB are incommensurable in square. And since the square on the rational line AB is rational [Margin: f — I.47] and equal to the sum of the squares of AG, GB, the sum of the squares of AG, GB will also be rational. Again, since — by lemma 1 of the preceding proposition — the rectangle contained by AF, FB was made equal to the square on CE, [Margin: g — VI.17] it is equal to FG^2 (because the angle AGB is right and FG is perpendicular to AB); hence the squares FG^2 , CE^2 are equal, and therefore the lines

Diagram. The construction for Proposition 34: a semicircle on the diameter AB with the perpendicular FG raised to the circumference and the chords AG, GB joined; below, the line CD bisected at E.

- G (apex, on the circumference): where the perpendicular meets the semicircle
- A (left endpoint of the diameter)

- F (on the diameter, near B): foot of the perpendicular FG
- B (right endpoint of the diameter)
- C, E, D (the lower line): the line CD bisected at E

FG, CE are equal. Therefore CD, being double CE, will also be double FG. Hence, by lemma 3 of the preceding proposition, $\text{rect}(AB, CD)$ will be double $\text{rect}(AB, FG)$ (since FG is half of the lesser line, CD). [Margin: h — X.22] But $\text{rect}(AB, CD)$, contained by rationals commensurable in square only, is medial. Therefore $\text{rect}(AB, FG)$ too, being commensurable with it since it is its half, is medial, by the corollary to proposition 24 of this book. And to $\text{rect}(AB, FG)$, by lemma 1 of the preceding proposition, the rectangle contained by AG, GB is equal. Therefore the rectangle contained by AG, GB is also medial. But it was shown that the sum of their squares is rational. Two lines AG, GB have therefore been found, incommensurable in square, which make the sum of their squares rational but the rectangle contained by them medial. Which was to be done.

SCHOLIUM.

It is demonstrated here, in a certain ancient scholium, that it is possible for two irrational spaces to compose a rational space, roughly in the following way.

Let a rational line AB be set out, together with two numbers C, D, of which C is the greater, not having to one another the ratio a square number has to a square number; and let it be arranged that as C is to D, so is the square on AB to the square on AE; and finally, with the square on AB described, let EF be drawn perpendicular to AB. Since, then, as C is to D, so is the square on AB to the square on AE, but C does not have to D the ratio a square number has to a square number, [Margin: i — X.9] the sides AB, AE of the said squares — squares not having to one another the ratio of a square to a square — will be incommensurable in length. And therefore, since AB, the whole, is incommensurable in length with the part AE, the same AB will also be incommensurable in length with the remainder EB, by the corollary to proposition 17 of this book. [Margin: k — VI.1] Now as AB is to AE, so is the square on AB to AF. Therefore, since AB, AE are incommensurable in length, [Margin: l — X.10] the square on AB and the rectangle AF will be incommensurable. Hence, the square on AB being rational — for AB too is posited rational — AF will be incommensurable with that square, and so irrational; and by the same argument we shall show that BF is irrational. But since AF, BF together compose the rational square on AB, it is clear that a rational can be produced from two irrationals. Which was proposed.

Diagram. The square on AB for the ancient scholium, with EF raised perpendicular from the point E on the base; the numbers C and D are set beside it as 6 and 4.

- F (top, above E): where the perpendicular EF meets the top side of the square
- A (bottom left): endpoint of AB
- E (bottom, point of division): foot of the perpendicular EF
- B (bottom right): endpoint of AB
- Numeric labels below the base: "C, 6. D, 4." (that is, $C = 6$ and $D = 4$)

But if AF, FB be rational, we shall show that the whole AFB composed of them is also rational. For since each of AF, FB is rational, they will be commensurable with one another. [Margin: m — X.16] Therefore the whole AFB composed of them will be commensurable with each of them. Hence AFB, the whole, being commensurable with each of the rationals AF, FB, [Margin: n — X def. 9] is itself rational too. Which was proposed.

PROBL. 11. PROPOS. 35.

[Margin: xxxiv. / xxvii.]

To find two straight lines incommensurable in square which make the sum of their squares medial, but the rectangle contained by them rational.

[Margin: a — X.32] Let two medial lines AB, CD, commensurable in square only, containing a rational rectangle, be taken, such that the greater, AB, is more powerful than the lesser, CD, by the square on a line incommensurable with it; and let the rest be carried out as in the preceding proposition. We shall then show, just as in the preceding proposition, that the lines AG, GB are incommensurable in square. And since the square on the medial AB, [Margin: b — I.47] being equal to the sum of the squares of AG, GB, is medial, the sum of the squares of AG, GB will also be medial. Again, as in the preceding proposition, we shall show that $\text{rect}(AB, CD)$ is double $\text{rect}(AB, FG)$, and hence that the former is commensurable with the latter. Therefore, since $\text{rect}(AB, CD)$ is rational by construction, $\text{rect}(AB, FG)$ too, being commensurable with it, will be rational. But by lemma 1 of proposition 33 of this book, the rectangle contained by AG, GB is equal to $\text{rect}(AB, FG)$. Therefore the rectangle contained by AG, GB is also rational. But it was shown that the sum of the squares of AG, GB is medial. Therefore the two lines AG, GB, which were shown to be incommensurable in square, make the

sum of their squares medial and the rectangle comprehended by them rational. Two lines AG, GB have therefore been found, incommensurable in square, which make the sum of their squares medial but the rectangle contained by them rational. Which was to be done.

Diagram. The construction for Proposition 35: a semicircle on the diameter AB with the perpendicular FG raised to the circumference and the chords AG, GB joined; below, the line CD bisected at E.

- G (apex, on the circumference): top of the perpendicular
- A (left endpoint of the diameter)
- F (on the diameter, near B): foot of the perpendicular FG
- B (right endpoint of the diameter)
- C, E, D (the lower line): the line CD bisected at E

PROBL. 12. PROPOS. 36.

[Margin: xxxv. / xxix.]

To find two straight lines incommensurable in square which make both the sum of their squares medial and the rectangle contained by them medial, and this rectangle incommensurable with the sum of their squares.

[Margin: a — X.33] Let two medial lines AB, CD, commensurable in square only, containing a medial rectangle, be taken, such that the greater, AB, is more powerful than the lesser, CD, by the square on a line incommensurable with it in length; and let the rest be carried out as in proposition 34. We shall then show, in like manner, that the lines AG, GB are incommensurable in square. And since the square on the medial AB is medial and equal to the sum of the squares of AG, GB, the sum of the squares of AG, GB will also be medial. Again, as in proposition 34, we shall demonstrate that $\text{rect}(AB, CD)$ is double $\text{rect}(AB, FG)$, and hence that the former is commensurable with the latter. Therefore, since by construction the rectangle contained by AB,

Diagram. The construction for Proposition 36: a semicircle on the diameter AB with the perpendicular FG raised to the circumference and the chords AG, GB joined; below, the line CD bisected at E.

- G (apex, on the circumference): top of the perpendicular
- A (left endpoint of the diameter)
- F (on the diameter, near B): foot of the perpendicular FG

- B (right endpoint of the diameter)
- C, E, D (the lower line): the line CD bisected at E

CD is medial, the rectangle contained by AB, FG — that is, the one contained by AG, GB, which by lemma 1 of proposition 33 of this book is equal to it — will also be medial, by the corollary to proposition 24 of this book. And since AB is posited incommensurable in length with CD, while CE is commensurable in length with the same CD (because CD is double CE), [Margin: c — X.13] AB, CE will be incommensurable in length. But as AB is to CE, so — by lemma 3 of proposition 19 of this book — is the square on AB to rect(AB,CE), that is, to rect(AB,FG), that is, to the rectangle under AG, GB (for the rectangles under AB, FG and under AG, GB are equal, by lemma 1 of proposition 33 of this book). [Margin: d — X.10] Therefore the square on AB is incommensurable with the rectangle under AG, GB. Two straight lines AG, GB have therefore been found, incommensurable in square, which make both the sum of their squares medial and the rectangle contained by them medial, and this incommensurable with the sum of their squares. Which was to be done.

SCHOLIVM.

From this problem we shall easily accomplish what, at proposition 24 of this book, we undertook to demonstrate — namely:

To find two medials incommensurable both in length and in square.

Since it has been shown that both the sum of the squares of the lines AG, GB and the rectangle contained by them are medial, and that this rectangle is incommensurable with that sum, the lines whose squares are that medial sum and this medial rectangle will likewise be medials incommensurable both in length and in square. For if they were commensurable in square, their squares too — that is, the sum of the squares of AG, GB and the rectangle under AG, GB — would be commensurable, which is not assumed. Therefore, if AB be taken whose square is the sum of the squares of AG, GB, and another line whose square is the rectangle under AG, GB — that is, the mean proportional between AG, GB — two medials will have been found incommensurable both in length and in square. Which was proposed.

PRINCIPIVM SENARIORVM

The Origin of the Six Compound Irrationals, by Composition

THEOR. 25. PROPOS. 37.

[Margin: xxxvi. / xxx.]

If two rational lines commensurable in square only be added together, the whole is irrational; and let it be called binomial (a line "of two names").

Let two rational lines AB, BC, commensurable in square only, found by lemma 2 of proposition 21 of this book, be added together. I say that the whole AC is irrational. For since AB is incommensurable in length with BC, and as AB is to BC, so is $\text{rect}(AB, BC)$ to the square on BC, by the lemma to proposition 31 of this book, [Margin: a — X.10] the rectangle under AB, BC will be incommensurable with the square on BC. But commensurable with the rectangle under AB, BC is its double — namely, that which is contained twice under AB, BC; and commensurable with the square on BC is the square on the line AB (for all these are rational). [Margin: b — X.16] Hence the sum of the squares of the lines AB, BC is also commensurable with the same square on BC. Therefore, by what we showed in the scholium to proposition 14 of this book, that which is contained twice under AB, BC is also incommensurable with the sum of the squares of the lines AB, BC. For this reason the sum of that which is contained twice under AB, BC and the sum of the squares of the lines AB, BC — that is, the square on the whole AC [Margin: c — II.4] (for this square is equal to the squares of the lines AB, BC together with the rectangle under AB, BC taken twice) — [Margin: d — X.17] will be incommensurable with the sum of the squares of the lines AB, BC. But the sum of the squares of the lines AB, BC is rational, being shown to be commensurable with the rational square on the rational line BC. Therefore the square on AC, being incommensurable with the rational square on BC, [Margin: e — X def. 10] is irrational; and so the line AC itself will be irrational. Let it be called "of two names," or, as others say, a binomial, because it is composed of two names — namely, of the two rational lines AB, BC, commensurable in square only. If, then, two rational lines commensurable in square only be added together, the whole will be irrational, etc. Which was to be shown.

Diagram. A single straight line divided into two segments, representing the binomial $AC = AB + BC$.

- A (left endpoint)
- B (point of division)
- C (right endpoint)

SCHOLIVM.

Thus from two rational lines commensurable in square only two irrational lines are produced. For the line which is the mean proportional between them [Margin: f — X.22] is irrational, and is called the medial; while the line composed of them [Margin: g — X.37] is irrational, and is called "of two names" (the binomial).

THEOR. 26. PROPOS. 38.

[Margin: xxxvij. / xxxj.]

If two medial lines commensurable in square only, containing a rational rectangle, be added together, the whole is irrational; and let it be called a first bimedial ("first from two medials").

Let two medials AB, BC, [Margin: a — X.28] found above, commensurable in square only, containing a rational rectangle, be added together. I say that the whole AC is irrational. For since AB is to BC as $\text{rect}(AB, BC)$ is to the square on BC, as was shown in the lemma to proposition 31 of this book, and AB, BC are

Euclid, Book X (Irrationals) — the six compound irrationals by composition

X.37 (Prop. 38: first bimedial) — conclusion of the demonstration ... they are incommensurable in length. Therefore the rectangle $AB \cdot BC$ and the square on BC are incommensurable [Margin: (b) Elements X.10]. But twice the rectangle $AB \cdot BC$ is commensurable with the rectangle $AB \cdot BC$, and the sum of the squares on the lines AB and BC is commensurable with the square on BC . (For since AB and BC are commensurable in square, their squares are commensurable [Margin: (c) Elements X.16], and hence the sum of their squares will also be commensurable with the square on BC .) Therefore twice the rectangle $AB \cdot BC$ and the sum of the squares on the lines AB and BC are incommensurable with one another, by what was demonstrated in the scholium to Prop. 14 of this book. Therefore the sum of the squares on AB and BC — that is, the square on AC , which is equal to that sum [Margin: (d) Elements II.4] — is likewise incommensurable with twice the rectangle $AB \cdot BC$ [Margin: (e) Elements X.7]. But the rectangle taken once on AB , BC is commensurable with twice the rectangle $AB \cdot BC$, since it is half of it. Therefore the square on AC is incommensurable with the rectangle $AB \cdot BC$ [Margin: (f) Elements X.13]. But the rectangle $AB \cdot BC$ is posited rational. Therefore the square on AC is irrational [Margin: (g) Elements X, def. 10], and on that account the line AC will also be irrational [Margin: (h) Elements X, def. 11]. Let it be called the first of two medials, or, as others put it, the first bimedial. If, then, two medials commensurable in square only be posited, etc. Which was to be shown.

Diagram. A single straight line divided into two segments, representing the first bimedial $AC = AB + BC$.

- A (left end)
- B (division point)
- C (right end)

LEMMA

The rectangle contained by a rational line and an irrational line is irrational.

Let the rectangle ABCD be contained by the rational line AB and the irrational line BC. I say that it is irrational. For if it be said to be rational, then, applied to the rational line AB, it will make its breadth BC rational [Margin: (i) Elements X.21]. But this is absurd, for BC is posited irrational. Therefore the rectangle AC is not rational; therefore it is irrational. Which was the thing proposed.

Diagram. A rectangle with a diagonal drawn from the upper-left to the lower-right corner. The top side AB is drawn as a broken (dashed) line.

- A (upper-left corner)
- B (upper-right corner)
- C (lower-right corner)
- D (lower-left corner)
- The diagonal AC divides the rectangle; side AB is the rational line, side BC the irrational line.

THEOR. 27. PROPOS. 39. [Margin: xxxviiij. / xxxij.]

(X.38 — *the second bimedial*)

If two medials commensurable in square only, containing a medial rectangle, be added together, the whole is irrational; let it be called the second of two medials.

Let two medials found above [Margin: (a) Elements X.29], AB and BC, commensurable in square only and containing a medial rectangle, be added together. I say that the whole line AC is irrational. Let a rational line DE be set out, and to it let there be applied [Margin: (b) Elements I.45] a rectangle DF equal to the square on AC; and to the same line DE let there be applied a second rectangle DG equal to the sum of the squares on the lines AB and BC. Now since the square on AC — that is, the rectangle DF — is equal to the two squares on AB and BC together with twice the rectangle AB·BC [Margin: (c) Elements II.4], the remainder HF will be equal to the remaining rectangle, namely that contained twice under AB, BC. But by hypothesis the rectangle AB·BC is medial; therefore twice the rectangle AB·BC — that is, HF — is also commensurable with it and medial, by the corollary to Prop. 24 of this book. Again, since the squares on the medials AB, BC, which are commensurable in square, are commensurable, the

figure compounded of them — namely the rectangle DG — will also be commensurable with either of them [Margin: (d) Elements X.16]. But each of the squares on the medials AB, BC is medial. Therefore DG too will be medial, by the corollary to Prop. 24 of this book. Since, then, the medial figures DG and HF are applied to the rational line DE (for GH is equal to the rational DE [Margin: (e) Elements I.34]), their breadths EG and GF will be rational, but incommensurable in length with DE [Margin: (f) Elements X.23]. Again, since AB and BC are incommensurable in length, and as AB is to CE, so is the square on AB to the rectangle AB·BC, by the third lemma to Prop. 19 of this book, the square on AB will be incommensurable with the rectangle AB·BC, as was shown in the scholium to Prop. 10 of this book. But the sum of the squares on AB and BC was shown to be commensurable with the square on AB, since it is double of it. Therefore, by what we said in the scholium to Prop. 14 of this book, the sum of the squares on AB and BC will also be incommensurable with twice the rectangle AB·BC — that is, with the rectangle HF. Since, then, as DG is to HF, so is EG to GF [Margin: (g) Elements VI.1], EG will be incommensurable in length with GF [Margin: (h) Elements X.10]. But it was already shown that EG and GF are rational. Therefore EG and GF are rational lines commensurable in square only, and hence the whole line EF, compounded of them, is irrational [Margin: (i) Elements X.37]. Therefore, by the preceding lemma, DF, contained by the rational line DE and the irrational line EF, is irrational; and on that account the square on AC, being equal to DF, is also irrational. Therefore the line AC too is irrational. Let it be called the second of two medials, or, as others prefer, the second bimedial. If, then, two medials commensurable in square only, etc. Which was to be demonstrated.

Diagram. At the top, a short straight line A—B—C (the second bimedial $AC = AB + BC$). Below it, a rectangle DF standing on the rational line DE (its left vertical side, D at top, E at bottom), divided by the vertical line HG into two rectangles: DG on the left and HF on the right.

- A, B, C (top line: A left end, B division point, C right end)
- D (upper-left corner of the rectangle)
- H (point on the top side where the dividing line meets it)
- E (lower-left corner)
- G (point on the bottom side where the dividing line meets it)
- F (lower-right corner)
- (The upper-right corner of the rectangle is unlabelled.)

SCHOLIVM

Euclid, in the preceding proposition, called the irrational line AC — the one compounded of two medials commensurable in square only and containing a rational rectangle — the first of two medials; but here he calls the irrational line AC — the one compounded of two medials commensurable in square only and containing a medial rectangle — the second of two medials, because the rational is prior to the medial (which is irrational) both by nature and in our knowledge, by Prop. 22 of this book.

LEMMA

If a straight line be cut into two unequal parts, the sum of the squares on the parts will exceed twice the rectangle contained by the parts by the square on the line by which the greater part exceeds the less.

Let the straight line AD be cut unequally at B, and let AB be the greater part; in it let BC be taken equal to the lesser part BD, so that AC is the excess by which AB exceeds BD — that is, BC equal to BD. I say that the squares on AB and BD together are greater than twice the rectangle AB·BD by the square on the line AC. For since the squares on AB and BC are equal to twice the rectangle AB·BC together with the square on AC [Margin: (k) Elements II.7], and BC is equal to BD, the squares on AB and BD will likewise be equal to twice the rectangle AB·BD together with the square on AC. Therefore the squares on AB and BD are greater than twice the rectangle AB·BD by the square on the line AC. Which was the thing proposed.

Diagram. A single straight line divided at three interior points.

- A (left end)
- C (first division point)
- B (second division point)
- D (right end)
- [Margin: (k) Elements II.7]

COROLLARIVM

From this it follows that the squares on unequal parts are, without qualification, greater than the rectangle twice contained by the unequal parts.

THEOR. 28. PROPOS. 40. [Margin: xxxix. / xxxiiij.]

(X.39 — *the major line*)

If two straight lines incommensurable in square be added together such that the sum of their squares is rational, but the rectangle contained by them is medial, the whole line will be irrational; let it be called the major.

Let two straight lines found above [Margin: (a) Elements X.34], AB and BC, incommensurable in square, be added together, making the sum of their squares rational but the rectangle contained by them medial. I say that the whole line AC is irrational. For since the rectangle AB·BC is posited medial, twice the rectangle AB·BC will also be commensurable with it and medial, by the corollary to Prop. 24 of this book, and hence irrational. But the sum of the squares on the lines AB, BC is posited rational. Therefore twice the rectangle AB·BC is incommensurable with the sum of the squares on the lines AB, BC [Margin: (b) Elements X, def. 10]. Therefore twice the rectangle AB·BC together with the squares on AB, BC — that is, the square on AC — is incommensurable with the sum of the squares on the lines AB, BC [Margin: (c) Elements X.17]. Since, then, this sum is posited rational, the square on AC will be incommensurable with it, and therefore irrational [Margin: (d) Elements X, def. 10]. And on that account the line AC is irrational [Margin: (e) Elements X, def. 11]. Let it be called the major, because — since AC is equal in square to the two squares on AB, BC together with twice the rectangle AB·BC — the sum of the squares on the lines AB, BC is greater than twice the rectangle AB·BC, by the preceding lemma [Margin: (f) Elements II.4]. Therefore, since the sum of the squares on AB, BC is rational while twice the rectangle AB·BC is medial, AC will rightly be called the major, since it is proper to take the name from the rational, which is the greater. If, then, two straight lines incommensurable in square be added together, etc. Which was to be demonstrated.

Diagram. A single straight line divided into two segments, representing the major line $AC = AB + BC$.

- A (left end)
- B (division point)
- C (right end)
- [Margin: (b) Elements X, def. 10; (c) Elements X.17]

THEOR. 29. PROPOS. 41. [Margin: xl. / xxxiv.]

(X.40 — the side of a rational plus a medial area)

If two straight lines incommensurable in square be added together such that the sum of their squares is medial, but the rectangle contained by them is rational, the whole line will be irrational; let it be called the "rational-and-medial-powered" (the side of a rational plus a medial area).

Let two straight lines found above [Margin: (a) Elements X.35], AB and BC, incommensurable in square, be added together, making the sum of their squares medial but the rectangle contained by them rational. I say that the whole line AC is irrational. For since the sum of the squares on the lines AB, BC is medial, while what is contained twice under AB, BC is rational — its half, namely the rectangle contained once under AB, BC, being posited rational — the sum of the squares on the lines AB, BC will be incommensurable with twice the rectangle AB·BC [Margin: (b) Elements X, def. 10]. Therefore the sum of the squares on the lines AB, BC together with twice the rectangle AB·BC — that is, the square on AC — is incommensurable with twice the rectangle AB·BC [Margin: (c) Elements X.17]. Since, then, twice the rectangle AB·BC is, as we said, rational, the square on AC will be incommensurable with it and irrational [Margin: (d) Elements X, def. 10]. And thereupon the line AC too will be irrational [Margin: (e) Elements X, def. 11]. Let it be called "rational-and-medial-powered," because it is equal in square to a medial — namely the sum of the squares on the lines AB, BC — and to a rational, namely the rectangle twice contained under AB, BC. And it is fitting for the rational to be set before the irrational. If, then, two straight lines incommensurable in square be added together, etc. Which was to be demonstrated.

Diagram. A single straight line divided into two segments ($AC = AB + BC$).

- A (left end)
- B (division point)
- C (right end)
- [Margin: (b) Elements X, def. 10; (c) Elements X.17]

THEOR. 30. PROPOS. 42. [Margin: xlj. / xxxv.]

(X.41 — the side of the sum of two medial areas)

If two straight lines incommensurable in square be added together such that they make both the sum of their squares medial and the rectangle

contained by them medial, and moreover incommensurable with the sum of their squares, the whole straight line will be irrational; let it be called the "power of two medials" (the side of the sum of two medial areas).

Let two straight lines found above [Margin: (a) Elements X.36], AB and BC, incommensurable in square, be added together, making the sum of their squares medial and the rectangle contained by them medial, and moreover incommensurable with the sum of their squares. I say that the whole line AC is irrational. Let a rational line DE be set out, and to it let there be applied [Margin: (b) Elements I.45] a rectangle DF equal to the square on AC; and let DG be applied equal to the sum of the squares on the lines AB, BC. Now since the square on AC — that is, the rectangle DF — is equal to the sum of the squares on the lines AB, BC together with twice the rectangle AB·BC [Margin: (c) Elements II.4], the remainder HF will be equal to twice the rectangle AB·BC. But since both the sum of the squares on the lines AB, BC (that is, the rectangle DG) and the rectangle AB·BC — and hence, by the corollary to Prop. 24 of this book, twice AB·BC, namely HF (being commensurable with AB·BC) — are posited medial, DH and HF, applied to the rational line DE, will make breadths EG and GF that are rational but incommensurable in length with DE [Margin: (d) Elements X.23]. Again, since the sum of the squares on the lines AB, BC (that is, the rectangle DG) is posited incommensurable with the rectangle AB·BC, and its double is commensurable with the rectangle AB·BC — namely what is contained twice under AB, BC, that is, HF — DG and HF will be incommensurable [Margin: (e) Elements X.13]. Therefore, since as DG is to HF, so is EG to GF [Margin: (f) Elements VI.1], EG and GF will be incommensurable in length [Margin: (g) Elements X.10]. But EG, GF were shown to be rational. Therefore EG, GF are rational lines commensurable in square only, and on that account the whole line EF, compounded of them, is irrational [Margin: (h) Elements X.37]. Therefore DF, contained by the rational line DE and the irrational line EF, is irrational, by the lemma to Prop. 38 of this book. Therefore the square on AC too, being equal to it, is irrational; and thereupon the line AC itself is irrational [Margin: (i) Elements X, def. 11]. Let it be called the "power of two medials," because it is equal in square to both the sum of the squares on the lines AB, BC and twice the rectangle AB·BC. If, then, two straight lines incommensurable in square be added together such that they make both the sum of their squares medial, etc. Which was to be demonstrated.

Diagram. At the top, a short straight line A—B[?]-C ($AC = AB + BC$). Below it, a rectangle DF standing on the rational line DE (left vertical side, D at top, E at

bottom), divided by the vertical line HG into rectangle DG (left) and rectangle HF (right).

- A, B[?], C (top line: A left end, division point read as B but printed glyph is ambiguous — could be P; C right end)
- D (upper-left corner)
- H (point on the top side at the dividing line)
- E (lower-left corner)
- G (point on the bottom side at the dividing line)
- F (lower-right corner)
- (The upper-right corner is unlabelled.)

LEMMA

If a straight line be cut into unequal parts, and again into other unequal parts, the squares on the more unequal parts together will be greater than the squares on the less unequal parts together.

Let the straight line AB be cut unequally at C, and again unequally at D, and let the former parts AC, CB be more unequal than the latter parts AD, DB. I say that the squares on AC, CB together are greater than the squares on AD, DB together. For let AB be bisected at E; the point D will fall either between E and C, or between A and E. First let it fall between E and C. Since, then, the rectangle AC·CB together with the square on EC is equal to the square on EB [Margin: (k) Elements II.5], and likewise the rectangle AD·DB together with the square on ED is equal to the same square on EB, the rectangle AC·CB together with the square on EC will be equal to the rectangle AD·DB together with the square on ED. Therefore, when the unequal squares on the unequal lines EC, ED are taken away — since the square on EC is greater than the square on ED — the remaining rectangle AC·CB will be less than the remaining rectangle AD·DB; and on that account twice the rectangle AC·CB will also be less than twice the rectangle AD·DB. Now since the square on AB is equal both to twice the rectangle AC·CB together with the squares on AC, CB, and to twice the rectangle AD·DB together with the squares on AD, DB [Margin: (l) Elements II.4], twice the rectangle AC·CB together with the squares on AC, CB will be equal to twice the rectangle AD·DB together with the squares on AD, DB. Therefore, since twice the rectangle AC·CB was shown to be less than twice the rectangle AD·DB, the remaining squares on AC, CB will be greater than the remaining squares on AD, DB. Which was the thing proposed.

Diagram. A straight line divided at interior points (first case, D between E and C).

- A (left end)
- E (midpoint / bisection point)
- D (division point)
- C (division point)
- B (right end)
- [Margin: (k) Elements II.5]

Now let D fall between A and E. Since, then, the parts AC, CB are posited more unequal than the parts AD, DB, AD (which is the lesser of the latter) will be greater than CB (which is the lesser of the former); and hence, since AE, EB are equal, the remainder EC will be greater than the remainder DE. Accordingly, since the rectangle AC·CB together with the square on EC is equal to the square on EB [Margin: (m) Elements II.5], and likewise the rectangle AD·DB together with the square on ED is equal to the square on AE — that is, to the same square on EB — the rectangle AC·CB together with the square on EC will be equal to the rectangle AD·DB together with the square on DE. Therefore, as before, we shall demonstrate that the squares on AC, CB are greater than the squares on AD, DB. Which was the thing proposed.

Diagram. A straight line divided at interior points (second case, D between A and E).

- A (left end)
- D (division point)
- E (midpoint / bisection point)
- C (division point)
- B (right end)
- [Margin: (m) Elements II.5]

THEOR. 31. PROPOS. 43. [Margin: xlij. / xxxvj.]

(X.42 — a binomial is divided into its terms at one point only)

A line composed of two terms (a binomial) is divided into its terms at one point only.

Let AB, a binomial, be divided at the point C into its terms, so that AC, CB are rational lines commensurable in square only, as Prop. 37 of this book requires. I say that AB cannot be divided at another point into other terms — that is, into other rational lines commensurable in square only. For if it be possible, let it be divided again into its terms at D. It is then evident that AB is not divided at C into

two equal parts; for if it were bisected, AC and CB would be commensurable in length, which is absurd, since they are posited rational lines commensurable in square only...

Diagram. Three straight lines, each with endpoints A (left) and B (right) and two interior division points C and D placed in different relative positions to illustrate the alternative (impossible) divisions.

- Line 1: A ——— C — D — B (C then D, near B)
- Line 2: A ——— D — C — B (D then C)
- Line 3: A — D ——— C — B (D near A, C near B) ...commensurable in square only. In the same way AB is not bisected at D either, since AD and DB too are commensurable in square only. Therefore AB is cut unequally both at C and at D, and consequently the parts AC, CB are either less unequal, or more unequal, than the parts AD, DB. And therefore, by the preceding lemma, the squares on AC, CB are either less, or greater, than the squares on AD, DB. (For the parts AD, DB — wherever the point D may fall — will not be equal to the parts AC, CB, each to each, that is, the greater to the greater and the lesser to the lesser. For on that supposition AB would be cut, in the second division, into the very same terms as in the first division — which is not what is assumed.) Now since, when unequal magnitudes are subtracted from equal ones, the excess of the remainders equals the excess of the magnitudes taken away, as we taught in the 16th axiom of Book I: the squares on AC, CB together with twice the rectangle under AC, CB equal the squares on AD, DB together with twice the rectangle under AD, DB [Margin: a — *Elements* II.4], since both the one sum and the other equal the square on AB. Hence it follows that the amount by which the removed sum of the squares on AC, CB exceeds the removed sum of the squares on AD, DB is the same as the amount by which the remaining twice-rectangle under AC, CB exceeds the remaining twice-rectangle under AD, DB.

But the excess of the sum of the squares on AC, CB over the sum of the squares on AD, DB is a rational space. (For since the lines AC, CB are rational, and their squares therefore rational, the sum of their squares will also be rational, by what we showed in the scholium to Proposition 34 of this book; and by the same reasoning the sum of the squares on AD, DB will be rational. Therefore, since a rational exceeds a rational by a rational, as we demonstrated in the scholium to Proposition 27 of this book, it is clear that the excess of the sum of the squares on AC, CB over the sum of the squares on AD, DB is a rational space.) Therefore the

excess of twice the rectangle under AC, CB over twice the rectangle under AD, DB is also a rational space [Margin: b — *Elements* X.22]. And since the rectangle under AC, CB is medial, twice the rectangle under AD, DB will be commensurable with it, by the corollary of Proposition 24 of this book, and therefore medial [Margin: c — *Elements* X.27]; and in the same way twice the rectangle under AC, CB will be medial. Therefore, since a medial does not exceed a medial by a rational, the excess of twice the rectangle under AC, CB over twice the rectangle under AD, DB will not be a rational space. But we showed that it is rational. This is absurd. Therefore a binomial AB is not divided into its terms at any point other than C. And so it is divided into its terms at one point only. Q.E.D.

Diagram. Three horizontal straight lines, each running from A on the left to B on the right, each marked with two interior division points showing alternative placements of the division:

- Line 1: A ——— C — D — B (C to the left of D, both toward the right end)
- Line 2: A ——— D — C — B (D to the left of C)
- Line 3: A — D ——— C — B (D near the middle, C toward the right)

Labels: A, B — endpoints of the line; C, D — the two candidate division points.

THEOR. 32. PROPOS. 44.

[Margin: xliij. / xxxvij.]

A first bimedial line is divided into its terms at one point only.

Let AB be a first bimedial, divided into its terms at the point C, so that AC, CB are medials commensurable in square only which contain a rational area, as Proposition 38 of this book requires. I say that AB cannot be divided at another point into other terms — terms which would likewise be medial lines commensurable in square only and containing a rational area. For, if it can be done, let it be divided into other terms AD, DB. Then, wherever the point D may fall, we shall prove — in the same way as in the preceding proposition — that the excess of twice the rectangle under AC, CB over twice the rectangle under AD, DB is the same as the excess of the sum of the squares on AC, CB over the sum of the squares on AD, DB.

But the excess of twice the rectangle under AC, CB over twice the rectangle under AD, DB is a rational space. (For since AC, CB are assumed to contain a rational area, twice the rectangle under AC, CB will be commensurable with what is

contained once under AC, CB, and so rational. In the same way, twice the rectangle under AD, DB will be rational. Therefore, since a rational exceeds a rational by a rational, as we showed in the scholium to Proposition 27 of this book, it is clear that the excess of twice the rectangle under AC, CB over twice the rectangle under AD, DB is a rational space.) Therefore the excess of the sum of the squares on AC, CB over the sum of the squares on AD, DB is also a rational space.

But since the lines AC, CB are medial and commensurable in square, their squares too will be medial and commensurable [Margin: a — *Elements* X.16]. Therefore the sum composed of them will be commensurable with each of them. So, since each of them is medial, the sum composed of them will also be medial, by the corollary of Proposition 24 of this book. In the same way we shall show that the sum of the squares on AD, DB is medial [Margin: b — *Elements* X.27]. Therefore, since a medial does not exceed a medial by a rational, the excess of the sum of the squares on AC, CB over the sum of the squares on AD, DB will not be a rational space. But we also showed it to be rational. This is absurd. Therefore AB, a first bimedial, is not divided into its terms at any point other than C. And so it is divided into its terms at one point only. Q.E.D.

Diagram. Three horizontal straight lines, each from A on the left to B on the right, each with two interior division marks showing alternative division points:

- Line 1: A ——— C — D — B (C to the left of D)
- Line 2: A ——— D — C — B (D to the left of C)
- Line 3: A — D ——— C — B (D toward the middle, C toward the right)

Labels: A, B — endpoints; C, D — the two candidate division points.

THEOR. 33. PROPOS. 45.

[Margin: xlv. / xxxviii.]

A second bimedial line is divided into its terms at one point only.

Let AB be a second bimedial, divided into its terms at the point C, so that AC, CB are medials commensurable in square only which contain a medial area, as Proposition 39 of this book requires. I say that AB cannot be divided at another point into other terms — terms which would likewise be medial lines commensurable in square only and containing a medial area. For, if it can be done, let it be divided into other terms AD, DB. Then, wherever the point D may fall, we shall show, as in Proposition 43, that the squares on AC, CB are either greater or less than the squares on AD, DB.

Let a rational line EF be set out [Margin: a — *Elements* I.45], and to it let there be applied the rectangle EG equal to the square on AB, and likewise EH equal to the squares on AC, CB. Then the remainder IG will be equal to what is contained twice under AC, CB, since the square on AB [Margin: b — *Elements* II.4] equals the squares on AC, CB together with twice the rectangle under AC, CB. In the same way, if to BF there is applied EK equal to the squares on AD, DB, the remainder LG will be equal to the rectangle comprehended twice under AD, DB.

Diagram. A square figure standing on the applied lines. Along the top edge the line runs A — C — D — B, with C and D marking division points (D close to B). The left side descends from E (below A) to the bottom-left corner F, and is subdivided by tick-marks. The bottom edge runs F — H — K — G. Two interior vertical lines rise from H and K to the points I and L on the upper interior edge. The figure is thereby partitioned into the rectangles named in the proof (EH, EK, IG, EG, KG, and the like).

- A, C, D, B (top edge): the divided line and its division points
- E, I, L (upper interior row): E the upper-left corner; I, L interior points
- F, H, K, G (bottom edge): F the lower-left corner, G the lower-right corner; H, K interior points

**

And since the squares on AC, CB are unequal to the squares on AD, DB, the rectangles EH, EK, which are equal to them, will also be unequal; and consequently the lines FH, FK will be unequal. Again, since the squares on AC, CB are greater — by the lemma of Proposition 39 of this book — than twice the rectangle under AC, CB, EH will also be greater than IG. Therefore EH is greater than half of EG, and hence the line FH is greater than half of FG [recte: the source prints "FH"; the sense requires "FG"]. By the same reasoning we shall show that FK is greater than half of FG. Therefore the parts FH, HG are unequal to the parts FK, KG, each to each.

Now since AC, CB are medial and commensurable in square, their squares too will be medial and commensurable. Therefore the sum composed of them will be commensurable with each of them [Margin: c — *Elements* X.16]. So, since each of them is medial, the sum composed of them — that is, EH — will also be medial, by the corollary of Proposition 24 of this book. By the same reasoning EK will be medial. Therefore EH, EK, applied to the rational line EF, produce as their widths FH, FK [Margin: d — *Elements* X.23], which are rational but incommensurable in length with EF. In the same way, since the rectangle under AC, CB is assumed

medial, what is twice under AC, CB — that is, IG — will be commensurable with it, and so medial, by the corollary of Proposition 24 of this book. Therefore, when it is applied to the rational line HI, HG will be rational but incommensurable in length with HI [Margin: e — *Elements* X.23]. In just the same way we shall show that EG is medial, and that KG is rational but incommensurable in length with KL.

Again, since AC, CB are incommensurable in length, and since, as AC is to CB, so — by the third lemma of Proposition 19 of this book — is the square on AC to the rectangle under AC, CB, the square on AC will be incommensurable with the rectangle under AC, CB [Margin: f — *Elements* X.10]. But the sum of the squares on AC, CB is commensurable with the square on AC. (For since AC, CB are commensurable in square, and therefore their squares commensurable, the sum composed of them will be commensurable with either of them [Margin: g — *Elements* X.10], namely with the square on AC.) And what is twice under AC, CB is commensurable with the rectangle under AC, CB. Therefore the sum of the squares on AC, CB — that is, the rectangle EH — is incommensurable, by the scholium to Proposition 14 of this book, with twice the rectangle under AC, CB, that is, with IG. Consequently [Margin: h — *Elements* VI.1], since as EH is to IG, so is FH to HG, the lines FH, HG will be incommensurable in length [Margin: i — *Elements* X.10]. But they were shown to be rational. Therefore FH, HG are rational and commensurable in square only. Therefore the whole FG is irrational [Margin: k — *Elements* X.37] — the kind called a binomial — and is divided into its terms at the point G. In the same way we shall show that FG is divided as a binomial into other terms at another point K. But this cannot be [Margin: l — *Elements* X.43], as was demonstrated in what precedes. Therefore AB, a second bimedral, is not divided into its terms at any point other than C. And so it is divided into its terms at one point only. Q.E.D.

THEOR. 34. PROPOS. 46.

[Margin: xlv. / xxxix.]

A major line is divided into its terms at one point only.

Let a major line AB be divided into its terms at the point C, so that AC, CB are incommensurable in square, making the sum of their squares rational but the rectangle under them medial, as Proposition 40 of this book requires. I say that AB cannot be divided at another point into other terms — lines which would likewise be incommensurable in square, making the sum of their squares rational and the rectangle under them medial. For, if it can be done, let it be divided into other terms at D.

Then, wherever the point D may fall, we shall demonstrate — in the same way as in Proposition 43 — that the excess of the sum of the squares on AC, CB over the sum of the squares on AD, DB is the same as the excess of twice the rectangle under AC, CB over twice the rectangle under AD, DB. But the excess of the sum of the squares on AC, CB over the sum of the squares on AD, DB is a rational space (because, since both sums are rational by hypothesis, their excess too will be a rational space, as we showed in the scholium to Proposition 27 of this book). Therefore the excess of twice the rectangle under AC, CB over twice the rectangle under AD, DB is also a rational space. Now since the rectangle under AC, CB is assumed medial, twice the rectangle under AC, CB will also be medial, by the corollary of Proposition 24 of this book, being commensurable with it; and in the same way twice the rectangle under AD, DB will be medial. Therefore, since a medial does not exceed a medial by a rational [Margin: a — *Elements* X.27], the excess of twice the rectangle under AC, CB over twice the rectangle under AD, DB will not be a rational space. But we showed that it is rational. This is absurd. Therefore a major line AB is not divided into its terms at any point other than C. And so it is divided into its terms at one point only. Q.E.D.

Diagram. A single horizontal straight line from A on the left to B on the right, with two interior division points: A — C — D — B (C toward the middle, D close to B).

- A, B: endpoints of the major line
- C: the true division point; D: the assumed second division point

THEOR. 35. PROPOS. 47.

[Margin: xlvj. / xl.]

The side of a rational plus a medial area is divided into its terms at one point only.

Let AB be the side of a rational plus a medial area, divided into its terms at the point C, so that AC, CB are incommensurable in square, making the sum of their squares medial but the rectangle under them rational, as Proposition 41 of this book requires. I say that AB cannot be divided at another point into other terms — lines which would likewise be incommensurable in square, making the sum of their squares medial and the rectangle under them rational. For, if it can be done, let it be divided into other terms at D.

Then, wherever the point D may fall, we shall show — just as in Proposition 43 of this book — that the excess of twice the rectangle under AC, CB over twice the

rectangle under AD, DB is the same as the excess of the sum of the squares on AC, CB over the sum of the squares on AD, DB; but the excess of twice the rectangle under AC, CB over twice the rectangle under AD, DB [recte: BD] is a rational space

Diagram. A single horizontal straight line from A on the left to B on the right, with two interior division points: A ——— C ——— D — B (C toward the middle, D close to B).

- A, B: endpoints of the line
- C: the true division point; D: the assumed second division point

**

— which we shall show, as in Proposition 44. Therefore the excess of the sum of the squares on AC, CB over the sum of the squares on AD, DB is also a rational space. But since the sums composed of these squares are assumed to be medial: now a medial does not exceed a medial by a rational [Margin: a — *Elements* X.27], and so their excess will not be a rational space. Yet we also showed it to be rational. This is absurd. Therefore AB, the side of a rational plus a medial area, is not divided into its terms at any point other than C. And so it is divided into its terms at one point only. Q.E.D.

THEOR. 36. PROPOS. 48.

[Margin: xlvij. / xlj.]

The side of the sum of two medial areas is divided into its terms at one point only.

Let AB be the side of two medial areas, divided into its terms at C, so that AC, CB are incommensurable in square, making both the sum of their squares medial and the rectangle under them medial, and the rectangle incommensurable with the sum of their squares, as Proposition 42 of this book requires. I say that AB cannot be divided at another point into other terms — lines which, namely, would likewise be incommensurable in square, making both the sum of their squares medial and the rectangle under them medial, and the rectangle incommensurable with the sum of their squares. For, if it can be done, let it be divided into other terms at the point D, wherever this point D may fall. Let the same construction be made as in Proposition 45, and we shall show, as there, that the parts FH, HG are unequal to the parts FK, KG, each to each.

Now, since the sum of the squares on AC, CB is assumed medial, EH — being equal to that sum — will also be medial. Again, since the rectangle under AC, CB is likewise assumed medial, IG — being equal to twice that rectangle — will also be medial, by the corollary of Proposition 24 of this book. Therefore the medials EH, IH, applied to the rational line EF (for IH is equal to EF), produce as their widths FH, HG [Margin: a — *Elements* X.23], which are rational but incommensurable in length with EF. By the same reasoning we shall prove that the lines FK, KG too are rational but incommensurable in length with EF. And since the sum of the squares described on AC, CB — that is, the rectangle EH — is incommensurable, by hypothesis, with twice the rectangle under AC, CB, namely with the rectangle IG [Margin: b — *Elements* VI.1]; and since, as EH is to IG, so is FH to HG; the lines FH, HG will be incommensurable in length, as we showed in the scholium to Proposition 10 of this book. But they were shown to be rational. Therefore FH, HG are rational and commensurable in square only. Therefore the whole FG is irrational — the kind called a binomial — and is divided into its terms at the point H. In just the same way we shall demonstrate that FG is divided as a binomial into other terms at another point K. But that this cannot be [Margin: c — *Elements* X.43] has already been demonstrated. Therefore AB, the side of two medial areas, is not divided into its terms at any point other than C. And so it is divided into its terms at one point only. Q.E.D.

Diagram. A square figure like that of Prop. 45. Along the top edge the line runs A — C — D — B (D close to B). The left side descends from E (below A) to the bottom-left corner F, subdivided by tick-marks. The bottom edge runs F — H — K — G. Two interior verticals rise from H and K to the points I and L on the upper interior edge, partitioning the square into the rectangles named in the proof (EH, IH, IG, and the rest).

- A, C, D, B (top edge): the divided line and its division points
- E, I, L (upper interior row): E the upper-left corner; I, L interior points
- F, H, K, G (bottom edge): F the lower-left corner, G the lower-right corner; H, K interior points

DEFINITIONES SECVNDÆ.

(Second set of Definitions.)

Let there be set out a rational line, and a binomial divided into its terms, such that the square on its greater term exceeds the square on the lesser by the square on a straight line commensurable in length with the greater.

I.

If the greater term is commensurable in length with the assigned rational, let the whole be called a **first binomial**.

II.

But if the lesser term is commensurable in length with the assigned rational, let it be called a **second binomial**.

III.

But if neither of the terms is commensurable in length with the assigned rational, let it be called a **third binomial**.

Again, let the square on the greater term exceed the square on the lesser by the square on a straight line incommensurable in length with the greater.

IV.

If the greater term is commensurable in length with the assigned rational, let it be called a **fourth binomial**.

V.

But if the lesser term [is commensurable in length with the assigned rational], let it be called a **fifth binomial**.

(Definition VI begins here as the page catchword and continues on the following page.)

VI.

But if neither of the two terms [is commensurable in length with the assigned rational], let it be called a **sixth binomial**.

SCHOLIUM.

The number of these six lines that are called binomials is arrived at as follows. Since the terms of a line called a binomial are rational lines commensurable in square only, both terms cannot be commensurable in length with the assigned rational line — for otherwise the terms themselves would also be lines commensurable in length with one another, as we showed in the scholium to proposition 12 of this book, which is not assumed. Rather, only one of them (namely the greater or the lesser), or neither, can be so. And thus three kinds of lines called binomials arise. Again, since the terms are unequal (for otherwise the

lines would be commensurable in length with one another, which is not assumed), the greater term can be more powerful than the lesser by the square on a line either commensurable or incommensurable in length with itself. And if indeed it is more powerful by the square on a line commensurable in length with itself, then, together with the three kinds already mentioned, three distinct binomial lines are formed, namely the first, second, and third binomials. But if it is more powerful by the square on a line incommensurable in length with itself, then, together with those same three kinds, another three distinct binomial lines are produced, namely the fourth, fifth, and sixth binomials, as is clear from the definitions Euclid has given here. There are therefore six distinct lines called binomials.

Euclid elegantly makes the first three in order those in which the greater term is more powerful than the lesser by the square on a straight line commensurable in length with itself, and the remaining three the second set, in which the greater term is more powerful than the lesser by the square on a straight line incommensurable in length with itself — since the commensurable naturally comes before the incommensurable, as is evident.

Again, and rightly, among the binomial lines he places first of all the one in which the greater term is incommensurable in length with the assigned rational line; and second the one in which the lesser term is commensurable in length with that same assigned rational line — since the greater naturally precedes the lesser, the lesser being contained by the greater; and third the one in which neither of the terms is commensurable in length with the assigned rational. And with the remaining three in the same way, calling the first of that second set the fourth, the second the fifth, and the third the sixth.

PROBL. 13. PROPOS. 49.

[Margin: xl.viiij. / xl.ij.]

To find a first binomial.

Given two square numbers AB, CB — from those we described in the second scholium to proposition 29 of this book — whose difference AC is not square, so that AB, CB have to one another the ratio a square has to a square, but AB, AC do not have to one another the ratio a square has to a square: let some rational line D be set out, and let EF be taken commensurable with it in length. Then EF too, being commensurable with the rational D, will be rational. Next, by the corollary to proposition 6 of this book, let it be arranged that as the number AB is to AC, so

is the square on EF to the square on FG. [Margin: a. 6.dec. — *Elements* X.6] I say that EG is a first binomial.

Diagram. A construction figure of the standard Book X type. At the top a dotted number-line runs from A on the left to B on the right, with C marked between them (representing the numbers AB, AC, CB as schematic arrays of units). Below it are the magnitude-lines: line **D** (the assigned rational), shown with internal division-ticks; a long line **EG** running left (E) to right (G), divided at **F** into the segments EF and FG (the two terms of the binomial); and beneath it a shorter line **H** (the line on whose square the greater square exceeds the lesser).

- A, C, B: endpoints and division-point of the dotted number-array (numbers AB, AC, CB)
- D: the assigned rational line
- E, F, G: the binomial line EG divided at F (terms EF, FG)
- H: the excess-line

For since the squares on EF and FG have to one another the ratio that the numbers AB, AC have, they are commensurable; [Margin: a] so the straight lines EF, FG will also be commensurable, at least in square. But EF was shown to be rational; therefore FG is rational too. And since AB does not have to AC the ratio a square has to a square, the squares on EF, FG will likewise not have the ratio a square number has to a square. [Margin: b. 9.dec. — *Elements* X.9] Therefore the straight lines EF, FG are incommensurable in length. So EF, FG are rational lines commensurable in square only; [Margin: c. 37.dec. — *Elements* X.37] and therefore the whole EG is irrational — the line called a binomial.

I say that it is also a first binomial. For since as the number AB is to the number AC, so is the square on EF to the square on FG, and since AB is greater than AC, the square on EF will also be greater than the square on FG. Let it be greater, by the lemma to proposition 14 of this book, by the square on the straight line H. Since, then, as the number AB is to AC, so is the square on EF to the square on FG, then also, by conversion of the ratio, as AB is to CB — that is, to the excess by which the antecedent AB exceeds the consequent AC — so is the square on EF to the square on H, namely to the excess by which the antecedent square on EF exceeds the consequent square on FG. But AB has to CB the ratio a square has to a square. Therefore the squares on EF and H will also have to one another the ratio a square number has to a square number; [Margin: d. 9.dec. — *Elements* X.9] and consequently the straight lines EF and H are commensurable in length. Since, then, the greater term EF is more powerful than the lesser FG by the square on the straight line H, which is commensurable in length with it, and since this same

greater term EF is commensurable in length with the assigned rational D, EG will, by definition, be a first binomial. We have therefore found a first binomial. Which was to be done.

PROBL. 14. PROPOS. 50.

[Margin: xlix. / xliij.]

To find a second binomial.

Given two square numbers AB, CB, as in the preceding proposition, and some rational line D having been set out, let FG be taken commensurable with it in length. Then FG too, being commensurable with the rational D, will be rational. Next, by the corollary to proposition 6 of this book, let it be arranged that as the number AC is to the number AB, so is the square on FG to the square on EF.

[Margin: a. 6.dec. — *Elements* X.6] I say that EG is a second binomial.

For since the squares on FG, EF, having the ratio that the numbers AC, AB have, are commensurable, [Margin: a] the straight lines FG, EF will also be commensurable, at least in square. But FG was shown to be rational; therefore EF is rational too. And since AC, AB do not have the ratio that square numbers have, neither will the squares on FG, EF have the ratio that square numbers have.

[Margin: b. 9.dec. — *Elements* X.9] Therefore the straight lines FG, EF are incommensurable in length. So EF, FG are rational lines commensurable in square only; [Margin: c. 37.dec. — *Elements* X.37] and therefore the whole EG is irrational — the line called a binomial.

I say that it is also a second binomial. For since as the number AC is to the number AB, so is the square on FG to the square on EF, then by conversion, as AB is to AC, so is the square on EF to the square on FG; and since AB is greater than AC, the square on EF will also be greater than the square on FG. Let it be greater, by the lemma to proposition 14 of this book, by the square on the straight line H. We shall now show, as in the preceding proposition, that H is commensurable in length with EF. Since, then, the greater term EF is more powerful than the lesser FG by the square on the straight line H, commensurable in length with it, and since the lesser term FG is commensurable in length with the assigned rational D, EG will, by definition, be a second binomial. We have therefore found a second binomial. Which was to be done.

PROBL. 15. PROPOS. 51.

[Margin: l. / xliv.]

To find a third binomial.

Given two square numbers AC, CB, as in proposition 49, let another number I be taken which has to neither of them, AB or AC, the ratio a square has to a square. This will be achieved if I is taken as the non-square number next greater than AC. For then, since it is not a square, it will not have to the square AB the ratio a square has to a square. Again, being the non-square next greater than AC, it will differ from AC either by a unit alone or by two. (By a unit when AC is a number to which adding a unit does not make a square; by two when a unit added to AC does make a square. For example, if AC is 8, the non-square next greater is 10, differing from 8 by two, because a unit added to 8 makes the square 9; but if AC is 5, the non-square next greater is 6, differing from 5 by a unit, because a unit added to 5 does not make a square, and so on.) Hence, as we showed in the scholium to proposition 8 of book 8, no mean proportional falls between I and AC. Therefore they will not be similar plane numbers, and so they will not have the ratio that square numbers have.

Diagram. The same construction figure, now with an additional number-row. At the top a dotted number-line runs from A (left) through C to B (right); beneath it a second, shorter dotted row is labelled I (the auxiliary number). Below these are the magnitude-lines: line D (the rational) with division-ticks; the long line EG running from E (left) to G (right), divided at F into EF and FG; and beneath it the shorter line H.

- A, C, B: the dotted number-array (numbers AB, AC, CB)
- I: the auxiliary number (second dotted row)
- D: the assigned rational line
- E, F, G: the binomial line EG divided at F (terms EF, FG)
- H: the excess-line

[Margin: l. / xvij.]

Now, some rational line D having been set out, let it be arranged, by the corollary to proposition 6 of this book, that as I is to AB, so is the square on D to the square on EF. [Margin: a. 6.dec. — *Elements* X.6] Then the squares on D and EF, having the ratio that the number I has to the number AB, will be commensurable; and so the lines D, EF will also be commensurable, at least in square. Since, then, D is rational, EF will be rational too. But since I to AB — that is, the square on D to the square on EF — does not have the ratio a square number has to a square number, [Margin: b. 9.dec. — *Elements* X.9] the straight lines D and EF will be incommensurable in length with one another.

Again, by the said corollary, let it be arranged that as AB is to AC, so is the square on EF to the square on FG. [Margin: c. 6.dec. — *Elements* X.6] Then the squares on EF, FG, having the ratio of number to number, will be commensurable; and hence the lines EF, FG are commensurable, at least in square. So, since EF was shown to be rational, FG will be rational too. And since AB to AC — that is, the square on EF to the square on FG — does not have the ratio a square number has to a square number, [Margin: d. 9.dec. — *Elements* X.9] EF, FG will be incommensurable in length. So EF, FG are rational lines commensurable in square only; [Margin: e. 37.dec. — *Elements* X.37] and therefore the whole EG is irrational, called a binomial.

I say that it is also a third binomial. For since as I is to AB, so is the square on D to the square on EF, and as AB is to AC, so is the square on EF to the square on FG, then, *ex aequali*, as I is to AC, so is the square on D to the square on FG. But I does not have to AC the ratio a square number has to a square number. Therefore neither will the squares on D and FG have the ratio a square number has to a square number; [Margin: f. 9.dec. — *Elements* X.9] and consequently the straight lines D and FG are incommensurable in length. Now since as AB is to AC, so is the square on EF to the square on FG, and since AB is greater than AC, the square on EF will also be greater than the square on FG. Let it then be greater, by the lemma to proposition 14 of this book, by the square on the straight line H. We shall now likewise show, as in proposition 49, that H is commensurable in length with EF. Since, then, the greater term EF is more powerful than the lesser FG by the square on the straight line H, commensurable in length with it, and since neither EF nor FG is commensurable in length with the assigned rational D, as has been demonstrated, EG will, by definition, be a third binomial. We have therefore found a third binomial. Which was to be done.

PROBL. 16. PROPOS. 52.

[Margin: l.j. / xlv.]

To find a fourth binomial,

Given two numbers AC, CB such that the number AB composed of them has to neither of them the ratio a square has to a square — from those we set out in the third scholium to proposition 29 of this book — let some rational line D be set out, and let EF be taken commensurable with it in length.

Diagram. The same construction figure. At the top a dotted number-line runs from A (left) through C to B (right). Below it are the magnitude-lines: line **D** (the

rational) with division-ticks; the long line **EG** running from E (left) to G (right), divided at **F** into EF and FG; and beneath it the shorter line **H**.

- A, C, B: the dotted number-array (numbers AC, CB, and their composite AB)
- D: the assigned rational line
- E, F, G: the binomial line EG divided at F (terms EF, FG)
- H: the excess-line

Then EF too will be rational, being commensurable with the rational D. If the rest is constructed as in proposition 49, we shall show, just as there, that the whole EG is a binomial. I say that it is also a fourth binomial. For again, as in proposition 49, the square on EF will be greater than the square on FG. Let it then be greater by the square on the straight line H. Since, then, in the same way as in proposition 49, by conversion of the ratio, as AB is to CB, so is the square on EF to the square on H; but AB is not to CB as a square to a square, neither will the square on EF be to the square on H as a square number to a square number. [Margin: a. 9.dec. — *Elements* X.9] Therefore the straight lines EF and H are incommensurable in length. And so, since the greater term EF is more powerful than the lesser FG by the square on the straight line H, incommensurable in length with it, and since the greater term EF is again commensurable in length with the assigned rational D, EG will, by definition, be a fourth binomial. We have therefore found a fourth binomial. Which was to be done.

PROBL. 17. PROPOS. 53.

[Margin: l.ij. / xl.vj.]

To find a fifth binomial.

Given (the figure of the preceding proposition being repeated) two numbers AC, CB, let the construction be made as in the preceding proposition, that is, as in proposition 50: let FG be taken commensurable in length with the assigned rational D, and so on. We shall then show, as in proposition 50, that EG is a binomial. I say that it is also a fifth binomial.

Diagram. The construction figure of the preceding proposition, repeated. At the top a dotted number-line runs from A (left) through C to B (right). Below it are the magnitude-lines: line **D** (the rational) with division-ticks; the long line **EG** running from E (left) to G (right), divided at **F** into EF and FG; and beneath it the shorter line **H**.

- A, C, B: the dotted number-array (numbers AC, CB)

- D: the assigned rational line
- E, F, G: the binomial line EG divided at F (terms EF, FG)
- H: the excess-line

For we shall prove, in the same way as in proposition 50, that the square on EF is greater than the square on FG. Let it then be greater by the square on the straight line H. And since, as was shown in proposition 49, by conversion of the ratio, as AB is to CB, so is the square on EF to the square on H, we shall show, as in the preceding proposition, that the straight lines EF and H are incommensurable in length. Hence, since the greater term EF is more powerful than the lesser FG by the square on the straight line H, incommensurable in length [recte: longitudine] with it, and since the lesser term FG is commensurable in length with the assigned rational D, EG will, by definition, be a fifth binomial. We have therefore found a fifth binomial. Which was to be done.

PROBL. 18. PROPOS. 54.

[Margin: l.iiij. / xl.vij.]

To find a sixth binomial.

Given two dissimilar plane numbers AC, CB, neither of which is a square, and such that the number AB composed of them is likewise not a square and has to neither of them the ratio a square has to a square number (this will be achieved if any non-square number is divided into two numbers prime to one another; [Margin: a. 30.sept. — *Elements* VII.30] for in this way the whole too will be prime to each of them, and therefore will not have to them the ratio a square has to a square, by what we demonstrated toward the end of book 8): let another number I be taken which has to neither AB nor AC the ratio a square has to a square — such as is any square number. For this, related to AB and AC, which are not squares, will not have the ratio a square has to a square.

Diagram. The construction figure, with an additional number-row. At the top a dotted number-line runs from A (left) through C[?] to B (right); the middle division-mark is malformed in the print. Beneath it is a second dotted row labelled **I** (the auxiliary square number). Below these are the magnitude-lines: line **D** (the rational) with division-ticks; the long line **EG** running from E (left) to G (right), divided at F into EF and FG; and beneath it the shorter line **H**.

- A, C[?], B: the dotted number-array (dissimilar plane numbers AC, CB, composite AB)
- I: the auxiliary square number (second dotted row)

- D: the assigned rational line
- E, F, G: the binomial line EG divided at F (terms EF, FG)
- H: the excess-line

Next let some rational line D be set out, and, by the corollary to proposition 6 of this book, let it be arranged that as I is to AB, so is the square on D to the square on EF; and let the rest be done as in proposition 51. We shall show, as there, that the straight lines D and EF are incommensurable in length, and that the whole EG is a binomial. I say that it is also a sixth binomial. For we shall prove, in the same way as in proposition 51, that D and FG are incommensurable in length, and that the square on EF is greater than the square on FG. Let it then be greater by the square on the straight line H. We shall also show, as in proposition 49, that as AB is to CB, so is the square on EF to the square on H. Since, then, AB does not have to CB the ratio a square number has to a square, neither will the square on EF have to the square on H the ratio a square number has to a square; [Margin: b. 9.dec. — *Elements* X.9] so EF and H are incommensurable in length. And so, since the greater term EF is more powerful than the lesser FG by the square on the straight line H, incommensurable in length with it, and since neither of the terms EF, FG is commensurable in length with the assigned rational D, EG will, by definition, be a sixth binomial. We have therefore found a sixth binomial. Which was to be done.

LEMMA.

If a straight line is cut in any way whatever, the rectangle contained by the parts will be a mean proportional between the squares on the parts; likewise the rectangle contained by the whole and one part will be a mean proportional between the square on the whole line and the square on that part.

Let the straight line AB be cut in any way at C. On AB describe the square ABDE, and in it draw the diagonal BE. From C draw the straight line CF parallel to BD, cutting the diagonal at G; and through G draw HI parallel to AB. Then, by the corollary to proposition 4 of book 2, FH, CI will be the squares on the parts AC, CB; while each of the rectangles DG, GA is contained by those same parts; and the rectangles CD, AI are contained by the whole AB and the part CB. I say that DG is a mean proportional between the squares FH, CI, and that CD is a mean proportional between the squares AD and CI.

Diagram. A square with its diagonal and two internal cross-lines. The square is ABDE: A at the bottom-left, B at the bottom-right, D at the top-right, E at the top-

left. The diagonal BE is drawn from B (bottom-right) up to E (top-left). From C, a point on the base AB, the line CF rises vertically to F on the top side ED, crossing the diagonal at the centre point G. Through G the horizontal line HI is drawn, with H on the left side AE and I on the right side BD. These lines divide the square into four smaller rectangles about the diagonal.

- E: top-left corner of the square
- F: point on the top side ED (foot of the vertical from C); printed as a Γ-shaped glyph
- D: top-right corner
- H: point on the left side AE (left end of the horizontal)
- G: centre, intersection of diagonal BE, vertical CF, and horizontal HI
- I: point on the right side BD (right end of the horizontal)
- A: bottom-left corner
- C: point on the base AB (foot of the vertical)
- B: bottom-right corner

For since, as HG is to GI, so is both FH to DG and AG to CI, [Margin: c. 1.sext. — *Elements* VI.1] it follows that as FH is to DG, so is AG to CI. But AG is equal to DG. [Margin: d. 43.pri. — *Elements* I.43] Therefore also, as FH is to DG, so is DG to CI; and thus DG is a mean proportional between the squares FH, CI.

Again, since, as AB is to CB, so is both AD to CD and AI to CI, [Margin: e. 1.sext. — *Elements* VI.1] but AI is equal to CD, therefore, as AD is to CD, so also is CD to CI. Hence CD [is a mean proportional...]

(Conclusion of the preceding Lemma on mean proportionals):

...CD is a mean proportional between the squares AD and CI. In the same way AF will be a mean proportional between the squares AD and FH.

THEOR. 37. PROPOS. 55.

[Margin: liv. / lvij.[?] — divergent lowercase-roman proposition counters]

If a space is contained by a Rational line and a first binomial, the straight line whose square equals that space is irrational, and is called a **binomial**.

Let the space AC be contained by the Rational line AB and the first binomial AD. I say that the straight line whose square equals the space AC is irrational, of the kind called a binomial. Let AE be the greater term of AD. Then by definition AE

and ED are rational and commensurable in square only; AE has a greater square than ED by the square on a straight line commensurable with AE in length; and finally AE is commensurable in length with the assigned Rational line AB.

Bisect ED at F. Now since AE has a greater square than ED by the square on a straight line commensurable in length with AE, if a parallelogram equal to a quarter of the square on ED — that is, to the square on EF — and contained by AG, GE be applied to AE (by the second lemma to proposition 17 of this book) so as to be deficient by a square figure, [Margin: (a) *Elements* X.18] it will divide AE into parts commensurable in length. Therefore the parts AG and GE are commensurable with one another in length. Now through the points G, E, F draw GH, EI, FK parallel to AB and CD. [Margin: (b) *Elements* II.14] Let a square LM be made equal to the parallelogram AH, and a square MN equal to the parallelogram GI, and let the squares LM and MN be joined at the angle M so that their sides MO and MP form a single straight line OP. Then their sides MQ and MR will likewise form a single straight line QR, as we demonstrated from Proclus at proposition 15 of Book I, because the angles OMQ [O printed as a filled ring] and PMR at the vertex M are equal, being right angles. When the rectangle LN has been completed — since the straight lines OM, MP are equal to the straight lines QM, MR, and hence the whole OP equal to the whole QR, [Margin: (c) *Elements* I.34] while OP is equal to SN and LT together and QR to LS and TN — the rectangle LN will be equilateral, and therefore a square.

Now the rectangle contained by AG, GE is equal, by construction, to the square on EF; [Margin: (d) *Elements* VI.17] therefore AG is to EF as EF is to GE. [Margin: (e) *Elements* VI.1] And consequently AH is to EK as EK is to GI. Therefore EK is a mean proportional between the squares LM, MN, to which AH and GI are equal. But TM is also a mean proportional between those same squares LM, MN, by the preceding lemma. Therefore TM is equal to EK. [Margin: (f) *Elements* I.43] Now since MS is equal to TM, [Margin: (g) *Elements* I.36] and FC is equal to EK, MS will also be equal to FC. Hence the whole square LN is equal to the whole rectangle AC; and so the straight line OP has for its square the space AC, contained by the Rational line AB and the first binomial AD. I say that OP is irrational, of the kind called a binomial.

For since AG, GE have been shown to be commensurable in length, [Margin: (h) *Elements* X.16] the whole AE will also be commensurable in length with each of them. But AE, being the greater term of the first binomial AD, is commensurable in length with the Rational line AB. Therefore AG and GE are, by the scholium to proposition 12 of this book, commensurable in length with AB as well. And since

AB is Rational, AG and GE will be Rational too. [Margin: (i) *Elements* X.20]
 Therefore the rectangles AH, GI, contained by Rational lines commensurable in length, are Rational; and so the squares LM, MN equal to them will be Rational; and consequently the straight lines OM, MP will be Rational.

And since AE is incommensurable in length with ED — while AG has been shown commensurable in length with AE, and EF, the half of ED, is commensurable with ED — then by the scholium to proposition 14 of this book AG and EF are incommensurable with one another in length. Therefore AH and EK, [Margin: (k) *Elements* VI.1] which have the same ratio as AG to EF, are incommensurable; [Margin: (l) *Elements* X.10] and so LM, MT, equal to them, are incommensurable. [Margin: (m) *Elements* X.10] Therefore the straight lines OM, MP are incommensurable in length, [Margin: (n) *Elements* VI.1] since they have the same ratio as LM to MT. But OM, MP have also been shown to be Rational. Therefore OM, MP are Rational and commensurable in square only. [Margin: (o) *Elements* VI.37] Consequently the whole OP, whose square is the space AC, is irrational, of the kind called a binomial. Therefore, if a space is contained by a Rational line and a first binomial, and so forth. Which was to be demonstrated.

Diagram. The figure for proposition 55, in two parts. *Left part:* the straight line AD, drawn horizontally, is divided at the points G, E, F (reading A–G–E–F–D). Perpendiculars dropped from these points meet the parallel baseline B–C at H (below G), I (below E), K (below F), with B below A and C below D; L continues the baseline to the right. The vertical rectangles so formed are AH, GI, EK, FK, etc., used in the applied-area construction. *Right part:* the square LN, with corners L (bottom-left), S (top-left), N (top-right), T (bottom-right); its center is M; the midpoints of the sides are O (left), P (right), R (top), Q (bottom); the horizontal midline OP and the vertical midline QR cross at M, dividing it into the two constituent squares LM and MN. This square LN is equal to the rectangle AC.

- Left figure, top: A, G, E, F, D
- Left figure, baseline: B, H, I, K, C (with L continuing right)
- Right figure (square LN), top: S, R, N
- Right figure, mid-height: O, M, P
- Right figure, baseline: L, Q, T

THEOR. 38. PROPOS. 56.

[Margin: lix.[?] / xlix. — divergent lowercase-roman proposition counters]

If a space is contained by a Rational line and a second binomial, the straight line whose square equals that space is irrational, and is called a **first bimedral**.

Let the space AC be contained by the Rational line AB and the second binomial AD. I say that the straight line whose square is AC is irrational, of the kind called a first bimedral. Let AE be the greater term of AD. Then by definition AE, ED are rational and commensurable in square only; AE has a greater square than ED by the square on a straight line commensurable with it in length; and finally ED is commensurable in length with the assigned Rational line AB. Bisect ED at F, and construct the rest as in the preceding proposition. This done, we shall prove in the same way, as there, that OP has for its square the space AC contained by the Rational line AB and the second binomial AD. I now say that OP is irrational, of the kind called a first bimedral.

For since AE is incommensurable in length with ED, and ED — the lesser term of the second binomial AD — is commensurable in length with the Rational line AB, [Margin: (a) *Elements* X.23] AE and AB [p. 443] will be incommensurable in length. And since AG, GE were shown in the preceding proposition to be commensurable in length, [Margin: (b) *Elements* X.16] the whole AE will also be commensurable with each of them. Therefore, since AE — the greater term of the second binomial AD — is a Rational line, AG and GE will also be Rational. Now since each of AG, GE is commensurable in length with AE, while AE is incommensurable in length with the Rational line AB, [Margin: (c) *Elements* X.14] each of AG, GE will be incommensurable in length with AB; and consequently both AB, AG and AB, GE are Rational and commensurable in square only. Therefore the rectangles AH, GI are medial, and so the squares LM, MN equal to them are medial. Hence the straight lines OM, MP [printed NP] are also medial.

Now since AG, GE are commensurable in length, [Margin: (e) *Elements* X.10] AH, GI, which have the same ratio as they, are commensurable, and so the squares LM, MN equal to them are commensurable. Therefore the straight lines OM, MP are commensurable, at least in square. And since AE, ED are incommensurable in length — while AG has been shown commensurable in length with AE, and EF, its half, commensurable in length with ED — then by the scholium to proposition 14 of this book AG, EF are incommensurable in length. [Margin: (f) *Elements* X.10] And so AH, EK, which have the same ratio as they, are incommensurable; therefore LM, MT, equal to AH and EK, are incommensurable; [Margin: (g) *Elements* X.10] and so the straight lines OM, MP are incommensurable in length, [Margin: (h) *Elements* VI.1] since they have the same ratio as LM to MT. Since,

then, it has been shown that OM, MP are medial and commensurable in square only — and since, finally, ED, the lesser term of the second binomial AD, is a line commensurable in length with AB, that is with EI, while EF is also commensurable in length with ED — [Margin: (i) *Elements* X.12] EI and EF will also be commensurable in length; and therefore, since EI is Rational, EF will be Rational too. [Margin: (k) *Elements* X.20] Hence the rectangle EK is Rational. But MT, contained by OM, MP, is equal to EK; therefore MT is also Rational. Consequently OM, MP are medial, commensurable in square only, and contain a Rational rectangle; [Margin: (l) *Elements* X.38] and so OP is irrational, of the kind called a first bimedial. Therefore, if a space is contained by a Rational line and a second binomial, and so forth. Which was to be shown.

Diagram. The figure for proposition 56, of the same construction as the preceding. *Left part:* the line AD divided at G, E, F, with perpendiculars to the baseline BC forming the rectangles AH, GI, etc. *Right part:* the square LN built from the two squares LM, MN, divided by the midlines OP and QR through the center M.

- Left figure, top: A, G, E, F, D
- Left figure, baseline: B, H, I, K, C (L continuing right)
- Right figure (square LN), top: S, R, N
- Right figure, mid-height: O, M, P
- Right figure, baseline: L, Q, T

THEOR. 39. PROPOS. 57.

[Margin: lvj. / L. — divergent lowercase-roman proposition counters]

If a space is contained by a Rational line and a third binomial, the straight line whose square equals that space is irrational, and is called a **second bimedial**.

Let the space AC be contained by the Rational line AB and the third binomial AD. I say that the straight line whose square is AC is irrational, of the kind called a second bimedial. Let AE be the greater term of AD. Then by definition AE, ED are rational and commensurable in square only; AE has a greater square than ED by the square on a straight line commensurable with it in length; and finally neither of them, AE, ED, is commensurable in length with the assigned Rational line AB. Bisect ED at F, and make the rest exactly as in proposition 55. In the same way, then, as there, we shall show that OP has for its square the space AC; and, as in the preceding proposition 56, that OM, MP are medial and commensurable in

square only — because AE is set incommensurable in length with the Rational line AB, just as there the same AE was incommensurable in length with AB.

Diagram. The figure for proposition 57, of the same construction. The labels are somewhat foxed; the right-hand square shows its top-left corner as "C"["?"] (where the other figures read "S") and its right-side midpoint as "P"["?"].

- Left figure, top: A, G, E, F, D
- Left figure, baseline: B, H, I, K, C (L continuing right)
- Right figure (square LN), top: C["?"], R, N
- Right figure, mid-height: O, M, P["?"]
- Right figure, baseline: L, Q, T

(Continuing the demonstration.) And since AG, GE are commensurable in length, while ED is incommensurable in length with the Rational line AB, that is with EI, [Margin: (a) *Elements* X.14] EF also will be incommensurable in length with EI. But EF, EI are Rational, since EF is equal to the Rational line AB... Therefore EF, EI are Rational and commensurable in square only. Hence EK is medial, and so MT, equal to EK and contained by OM, MP, is medial. [Margin: (b) *Elements* X.22] And since OM, MP are medial, commensurable in square only, and contain a medial rectangle, [Margin: (c) *Elements* X.22] OP is irrational, of the kind called a second binomial. If, therefore, a space is contained by a Rational line and a third binomial, and so forth. Which was to be demonstrated.

THEOR. 40. PROPOS. 58.

[Margin: lvij. / Lj. — divergent lowercase-roman proposition counters]

If a space is contained by a Rational line and a fourth binomial, the straight line whose square equals that space is irrational, and is called a **major**.

Let the space AC be contained by the Rational line AB and the fourth binomial AD. I say that the straight line whose square equals the space AC is irrational, of the kind called a major. Let AE be the greater term of AD. Then by definition AE, ED are rational and commensurable in square only; AE has a greater square than ED by the square on a straight line incommensurable with it in length; and finally AE is commensurable in length with AB. Bisect ED at F, and make all the rest as in proposition 55. [Margin: (a) *Elements* X.19] Then AG, GE will be incommensurable in length, [p. 444] just as there, and OP will have for its square the space AC. I say that OP is irrational, of the kind called a major.

For since AG, GE are incommensurable in length, [Margin: (b) *Elements* X.10] the rectangles AH, GI, which have the same ratio as they, will also be incommensurable; and hence the squares LM, MN, equal to AH, GI, will be incommensurable. Therefore the straight lines OM, MP are incommensurable in square. But since AE, the greater term of the fourth binomial AD, is a line commensurable in length with the Rational line AB, AE will be Rational; [Margin: (c) *Elements* X.20] and the rectangle AI contained by them is Rational. Now AI is equal to the sum of the squares LM, MN. Therefore the sum of the squares LM, MN is Rational.

And since ED, the lesser term of the fourth binomial AD, is a line incommensurable in length with the Rational line AB, EF, its half, will also be incommensurable in length with AB; and EF, being commensurable with the Rational line ED, is Rational. Therefore EF and AB are Rational and commensurable in square only. [Margin: (d) *Elements* X.22] Hence EK, contained by them, is medial; and so MT, equal to it and contained by OM, MP, is medial. Therefore, since OM, MP are incommensurable in square, and make the sum of their squares LM, MN Rational, while the rectangle MT contained by them is medial, [Margin: (e) *Elements* X.40] the whole OP will be irrational, of the kind called a major. Therefore, if a space is contained by a Rational line and a fourth binomial, and so forth. Which was to be shown.

Diagram. The figure for proposition 58, of the same construction as the foregoing. This impression is heavily foxed and several interior labels are faint; the readable labels are listed below and the whole figure is flagged for re-examination.

- Left figure, top: A, G, E, F, D
- Left figure, baseline: B, H, I, K, C (L continuing right)
- Right figure (square LN): O and M legible at mid-height; other corner labels (S, R, N, P, Q, T) faint/illegible on this impression

THEOR. 41. PROPOS. 59.

[Margin: lviii. / Lij. — divergent lowercase-roman proposition counters]

If a space is contained by a Rational line and a fifth binomial, the straight line whose square equals that space is irrational, and is called **the side of a rational plus a medial area** [potens Rationale & Medium].

Let the space AC be contained by the Rational line AB and the fifth binomial AD. I say that the straight line whose square is the space AC is irrational, of the kind

called the side of a rational plus a medial area. Let AE be the greater term of AD. Then by definition AE, ED are rational and commensurable in square only; AE has a greater square than ED by the square on a straight line incommensurable with it in length; and finally ED is commensurable in length with the assigned Rational line AB. Bisect ED, and make the rest the same as in proposition 55. [Margin: (a) *Elements* X.19] Then again AG, GE will be incommensurable in length. And in the same way as in proposition 55, it will be established that OP has for its square the space AC. I say that OP is irrational, of the kind called the side of a rational plus a medial area.

For, as in the preceding proposition, the straight lines OM, MP will be incommensurable in square. And since AE — the greater term of the fifth binomial AD — is a line incommensurable in length with the Rational line AB, AE and AB will be Rational and commensurable in square only. [Margin: (b) *Elements* X.22] Therefore the rectangle AI contained by them is medial. Now AI is equal to the sum of the squares LM, MN; therefore this sum too is medial. Again, since ED is set Rational and commensurable in length with the Rational line AB — being the lesser term of the fifth binomial AD — EF, its half, will also be commensurable in length with AB, and Rational. [Margin: (c) *Elements* X.20] Hence EK, contained by the Rational lines EI, EF that are commensurable in length, is Rational; and therefore MT, contained by OM, MP, will be Rational, since it is equal to EK. And so, since the straight lines OM, MP are incommensurable in square, and make the sum of their squares LM, MN medial, while the rectangle MT contained by them is Rational, [Margin: (d) *Elements* X.41] the whole OP will be irrational, of the kind called the side of a rational plus a medial area. If, therefore, a space is contained by a Rational line and a fifth binomial, and so forth. Which was to be demonstrated.

Diagram. The figure for proposition 59, of the same construction. *Left part:* line AD divided at G, E, F, with perpendiculars to the baseline BC. *Right part:* the square LN built from the squares LM, MN, with midlines OP and QR through the center M.

- Left figure, top: A, G, E, F, D
- Left figure, baseline: B, H, I, K, C (L continuing right)
- Right figure (square LN), top: S, R, N
- Right figure, mid-height: O, M, P
- Right figure, baseline: L, Q, T

THEOR. 42. PROPOS. 60.

[Margin: lix. / Liiij. — divergent lowercase-roman proposition counters]

If a space is contained by a Rational line and a sixth binomial, the straight line whose square equals that space is irrational, and is called **the side of the sum of two medial areas** [bina Media potens].

Let the space AC be contained by the Rational line AB and the sixth binomial AD. I say that the straight line whose square is the space AC is irrational, of the kind called the side of the sum of two medial areas. Let AE be the greater term of AD. Then by definition AE, ED are rational and commensurable in square only; AE has a greater square than ED by the square on a straight line incommensurable with it in length; and finally neither of them, AE, ED, will be commensurable in length with the Rational line AB. Make everything as in the foregoing propositions; [Margin: (a) *Elements* X.19] then AG, GE will be incommensurable in length. And we shall now show in the same way, as in proposition 55, that the straight line OP has for its square the space

Diagram. The figure for proposition 60, of the same construction. *Left part:* line AD divided at G, E, F, with perpendiculars to the baseline BC. *Right part:* the square LN built from LM, MN, with midlines OP and QR through the center M.

- Left figure, top: A, G, E, F, D
- Left figure, baseline: B, H, I, K, C (L continuing right)
- Right figure (square LN), top: S, R, N
- Right figure, mid-height: O, M, P
- Right figure, baseline: L, Q, T

[...continuation of the demonstration of the preceding proposition (THEOR. 42 / PROPOS. 60, the side of two medials)...]

[...] AC. Likewise, as in Proposition 58, the lines OM, MP are incommensurable in square. And again, as in the preceding proposition, the sum of the squares on LM, MN will be Medial. But, as in Proposition 58, the rectangle MT contained by OM, MP will likewise be Medial. Now of the two lines AE, EF, the one is incommensurable in length with ED, while the other is commensurable with it [Margin: b — X.13]; therefore AE and EF are incommensurable in length [Margin: c — X.10]. Consequently AI and EK are also incommensurable, since they have the same ratio as AE, EF [Margin: d — VI.1]. And so the sum of the squares on LM, MN — which is equal to AI — and the rectangle MT — which is equal to EK — are incommensurable. Therefore, since the lines OM, MP are incommensurable in

square, and produce a sum of their squares LM, MN that is Medial, and a rectangle MT contained by them that is Medial and incommensurable with the sum of their squares, the whole OP will be Irrational, the kind called *the side of two medials* [bina media potens] [Margin: e — X.42]. If, then, an area is contained by a Rational line and a sixth binomial, and so on. Which was to be shown.

Diagram. Two figures belonging to the preceding proposition (the side of two medials).

Left figure: a rectangle whose upper edge runs from A (upper-left corner) rightward through the marked points G, E, F to D (upper-right corner), and whose lower edge runs from B (lower-left corner) through H, I, K to C (lower-right corner). Vertical divisions drop from the upper points to the base, dividing the figure into strips.

- A (upper-left corner) / B (lower-left corner): the left end of the divided line and its foot
- G, E, F (upper edge, interior): division points of the line AD
- D (upper-right corner) / C (lower-right corner): the right end
- H, I, K (lower edge, interior): feet of the perpendiculars

Right figure: a square with a small square (S) erected above its top edge, subdivided by two perpendicular midlines crossing at the center M.

- R (top-left corner), N (top-right corner)
- O (midpoint of left side), M (center), P (midpoint of right side)
- L (bottom-left corner), Q (midpoint of bottom edge), T (bottom-right corner)
- S: small square erected on the top edge

THEOR. 43. PROPOS. 61.

[Margin: lx / liv]

The square on a binomial, applied to a Rational line, produces as breadth a first binomial.

Let AB be a binomial whose greater term is AC [Margin: a — I.45]; and to the assigned Rational line DE let there be applied a rectangle DF equal to the square on AB, producing the breadth DG. I say that DG is a first binomial.

For to the same Rational line DE let there be applied the rectangle DH equal to the square on AC, and to HI another rectangle IK equal to the square on CB. The remainder LF will then be equal to twice the rectangle contained by AC, CB, since

the squares on AC, CB together with twice the rectangle contained by AC, CB are equal to the square on AB [Margin: b — II.4], just as the rectangle DF is also equal, by construction, to the square on AB. Let LG be bisected at the point M, and through M let MN be drawn parallel to LK, GF; then each of the two rectangles LN, MF will be equal to the rectangle contained by AC, CB.

Now since AC, CB are Rational lines commensurable in square only — because the whole AB is a binomial — the squares on AC, CB are Rational, and therefore commensurable [Margin: c — X.37]; and since the sum compounded of them is also commensurable with each of them, the sum of the squares on AC, CB will likewise be Rational [Margin: d — X.16]. But by construction the rectangle DK is equal to this sum. Therefore DK too will be Rational; and since it is applied to the Rational line DE, it will produce a breadth DL that is Rational and commensurable in length with DE.

Again, since AC, CB are Rational lines commensurable in square only, the rectangle contained by them will be Medial [Margin: e — X.22]; and hence twice that rectangle, being commensurable with it — that is, LF itself — will be Medial, by the corollary to Proposition 24 of this book. Therefore LF, applied to the Rational line LK, produces a Rational breadth LG that is incommensurable in length with LK — that is, with DE [Margin: f — X.23]. But DL has been shown commensurable in length with DE. Therefore DL, LG are incommensurable in length [Margin: g — X.13]. Hence DL, LG are Rational lines commensurable in square only; and consequently DG is a binomial [Margin: h — X.37]. I say further that it is a first binomial.

For since, by the lemma to Proposition 54 of this book, the rectangle contained by AC, CB is a mean proportional between the squares on AC, CB, LN will likewise be a mean proportional between DH, IK [Margin: i — VI.1]; and so, since the lines DI, LM, IL have the same ratio as DH, LN, IK, the line LM will also be a mean proportional between DI, IL [Margin: k — VI.17]. Therefore the rectangle contained by DI, IL is equal to the square on LM. And since the squares on the lines AC, CB are commensurable — because AC, CB were assumed commensurable in square — DH, IK, being equal to them, will also be commensurable; and therefore the lines DI, IL, having the same ratio as they, are commensurable in length [Margin: l — X.10]. Now since DK is greater than LF — because the squares on AC, CB are greater, by the lemma to Proposition 39 of this book, than twice the rectangle contained by AC, CB — the line DL will also be greater than LG, since DL, LG have the same ratio as DK, LF [Margin: m — VI.1]. Accordingly, since DL is greater than LG, and to DL is applied a rectangle

contained by DI, IL, deficient by a square figure, equal to the square on LM — that is, to a fourth part of the square described on the lesser line LG (for the rectangle contained by DI, IL was shown equal to the square on LM) — and since DL is divided at I into parts DI, IL commensurable in length, as has been demonstrated, DL, the greater term, will be more powerful than LG, the lesser, by the square on a line commensurable in length with itself [Margin: n — X.18]. Therefore, since DG has been shown to be a binomial, and its greater term DL is more powerful than its lesser term LG by the square on a line commensurable in length with itself, and moreover the greater term DL is commensurable in length with the assigned Rational line DE, DG will by the definition be a first binomial. Therefore the square on a binomial, and so on. Which was to be demonstrated.

Diagram. The construction for Proposition 61. At the left is the binomial line drawn vertically: B (top), C (the division point), A (foot). To the right stands the applied rectangle whose upper edge runs D, I, L, M, G (left to right) and whose base runs E, H, K, N, F (beneath D...G); two squares are erected above the upper edge over its subdivisions.

- B (top) / C (division point) / A (foot): the binomial AB divided at C into greater part AC and lesser CB
- D (upper-left corner) ... G (upper-right corner): the breadth DG, with interior points I, L, M
- E (lower-left corner) ... F (lower-right corner): the base, with interior feet H, K, N
- DE (left side): the assigned Rational line
- The two erected squares: the squares on AC and on CB

THEOR. 44. PROPOS. 62.

[Margin: lxj / lv]

The square on a first bimedial, applied to a Rational line, produces as breadth a second binomial.

Let AB be a first bimedial whose greater term is AC [Margin: a — I.45]; and to the Rational line DE let there be applied a rectangle DF equal to the square on AB, producing the breadth DG. I say that DG is a second binomial.

For let the same construction be set up as in the preceding proposition, so that again DH, IK are equal to the squares on AC, CB, and each of LN, MF equal to the rectangle contained by AC, CB. Now since AC, CB — the components of the first bimedial AB — are Medial lines commensurable in square only which contain a

Rational rectangle [Margin: b — X.38], the squares on AC, CB, and therefore the rectangles DH, IK equal to them, will be commensurable and Medial [Margin: c — X.16]. Since therefore the whole DK is commensurable with each of DH, IK, DK too will be Medial, by the corollary to Proposition 24 of this book; and since it is applied to the Rational line DE, its breadth DL will be Rational but incommensurable in length with DE [Margin: d — X.23].

Again, since the rectangle contained by AC, CB is Rational, its double LF will also be Rational; and since it is applied to the Rational line LK, its breadth LG will be Rational and commensurable in length with LK — that is, with DE [Margin: e — X.21]. Therefore, of the two lines DL, LG, since LG is commensurable in length with DE while DL is incommensurable in length, DL, LG will be incommensurable in length [Margin: f — X.13]. And since DL, LG have been shown Rational, they will be Rational lines commensurable in square only; and consequently the whole DG is a binomial [Margin: g — X.37].

Now, just as in the preceding proposition, we shall demonstrate that DL is the greater term and is more powerful than the lesser term LG by the square on a line commensurable in length with itself. Therefore, since the greater term DL of DG is more powerful than the lesser term LG by the square on a line commensurable in length with itself, and the lesser term LG has been shown commensurable in length with the assigned Rational line DE, DG will by the definition be a second binomial. Therefore the square on a first bimedial, and so on. Which was to be shown.

Diagram. The construction for Proposition 62, identical in scheme to the preceding. At the left, the bimedial line vertically: B (top), C (division point), A (foot). To the right, the applied rectangle: upper edge D, I, L, M, G; base E, H, K, N, F; two squares erected above.

- B / C / A: the first bimedial AB divided at C into AC, CB
- D ... G (upper edge, interior points I, L, M): the breadth DG
- E ... F (base, interior feet H, K, N)
- DE (left side): the assigned Rational line

THEOR. 45. PROPOS. 63.

[Margin: lxij / lvj]

The square on a second bimedial, applied to a Rational line, produces as breadth a third binomial.

Let AB be a second binomial whose greater term is AC [Margin: a — I.45]; and to the Rational line DE let there be applied a rectangle DF equal to the square on AB, producing the breadth DG. I say that DG is a third binomial.

For with the same construction as in Proposition 61: since AC, CB — the components of the second binomial AB — are Medial lines commensurable in square only which contain a Medial rectangle [Margin: b — X.39], the squares on AC, CB, and therefore the rectangles DH, IK equal to them, will be commensurable and Medial [Margin: c — X.16]. Since therefore the whole DK is commensurable with each of DH, IK, DK too will be Medial, by the corollary to Proposition 24 of this book; and since it is applied to the Rational line DE, its breadth DL will be Rational but incommensurable in length with DE [Margin: d — X.23].

Again, since the rectangle contained by AC, CB is Medial, its double LF will also be Medial; and since it is applied to the Rational line LK, its breadth LG will be Rational but incommensurable in length with LK — that is, with DE [Margin: e — X.23]. And since AC is incommensurable in length with CB, and as AC is to CB, so — by the third lemma, Proposition 19 of this book — is the square on AC to the rectangle contained by AC, CB, the square on AC will also be incommensurable with the rectangle contained by AC, CB [Margin: f — X.10]. But the square on AC is commensurable with the sum of the squares on the lines AC, CB — because the squares on AC, CB are commensurable, since the lines themselves are assumed commensurable in square [Margin: g — X.16]; and the rectangle contained by AC, CB is commensurable with its double, namely twice the rectangle contained by AC, CB. Therefore the sum of the squares on the lines AC, CB — that is, the rectangle DK — is incommensurable with twice the rectangle contained by AC, CB — that is, with the rectangle LF — by what we wrote in the scholium to Proposition 14 of this book. Hence the lines DL, LG, which have the same ratio as DK, LF, are incommensurable in length [Margin: h — X.10]; but they have also been shown Rational. They are therefore Rational lines commensurable in square only; and consequently the whole DG is a binomial [Margin: i — X.37].

Now, just as in Proposition 61, we shall show that DL is the greater term and is more powerful than the lesser LG by the square on a line commensurable in length with itself. Therefore, since the greater term DL is more powerful than the lesser LG by the square on a line commensurable in length with itself, and neither DL nor LG is commensurable in length with the assigned Rational line DE, DG will by the definition be a third binomial. Therefore the square on a second binomial, applied to a Rational line, produces as breadth a third binomial, and so on. Which was to be demonstrated.

Diagram. The construction for Proposition 63, identical in scheme. Left: the bimedral line B (top) / C (division) / A (foot). Right: the applied rectangle, upper edge D, I, L, M, G; base E, H, K, N, F.

- B / C / A: the second bimedral AB divided at C into AC, CB
- D ... G (interior I, L, M): the breadth DG
- E ... F (base, feet H, K, N)
- DE (left side): the assigned Rational line

THEOR. 46. PROPOS. 64.

[Margin: lxij / lvij]

The square on a major, applied to a Rational line, produces as breadth a fourth binomial.

Let AB be a major whose greater term is AC [Margin: a — I.45]; and to the Rational line DE let there be applied a rectangle DF equal to the square on AB, producing the breadth DG. I say that DG is a fourth binomial.

For let exactly the same construction be made as in Proposition 61. Since AC, CB — the components of the major AB — are incommensurable in square, and make the sum of the squares on the lines AC, CB Rational, but the rectangle contained by them Medial [Margin: b — X.45], DK, being equal to the sum of the squares on the lines AC, CB, will also be Rational; whereas LF, twice the rectangle contained by AC, CB, will be Medial. Since, therefore,

the Rational DK is applied to the Rational line DE, DL will be Rational and commensurable in length with DE [Margin: c — X.21]. Likewise, since the Medial LF is applied to the Rational line LK, LG will be Rational but incommensurable in length with LK — that is, with DE [Margin: d — X.23]. Therefore, of the two lines DL, LG, since the one is commensurable in length with DE while the other is incommensurable in length with the same DE, DL, LG will be incommensurable in length [Margin: e — X.13]; but they have also been shown Rational. Therefore DL, LG [recte: LG] are Rational lines commensurable in square only; and hence DG is a binomial [Margin: f — X.37].

Now, just as in Proposition 61, we shall demonstrate that the rectangle contained by DI, IL is equal to the square on LM. But since the squares on AC, CB are incommensurable — because the lines AC, CB are incommensurable in square — the equal rectangles DH, IK will also be incommensurable; and so too the lines DI, IL, which have the same ratio as they, will be incommensurable in length

[Margin: g — X.10]. And since, as we showed in Proposition 61, DL is greater than LG, and to DL there is applied a rectangle contained by DI, IL, equal to the square on LM — that is, to a fourth part of the square on LG — deficient by a square figure, which divides DL at I into parts incommensurable in length, DL will be more powerful than LG by the square on a line incommensurable in length with itself [Margin: h — X.19]. For this reason, since DL itself (the greater term of DG, which is a binomial) has been shown commensurable in length with the assigned Rational line DB [recte: DE], DG will by the definition be a fourth binomial. Therefore the square on a major, applied to a Rational line, and so on. Which was to be demonstrated.

Diagram. The construction for Proposition 64, identical in scheme. Left: the major line B (top) / C (division) / A (foot). Right: the applied rectangle, upper edge D, I, L, M, G; base E, H, K, N, F.

- B / C / A: the major AB divided at C into AC, CB
- D ... G (interior I, L, M): the breadth DG
- E ... F (base, feet H, K, N)
- DE (left side): the assigned Rational line

THEOR. 47. PROPOS. 65.

[Margin: lxiv / lvij]

The square on the side of a rational plus a medial [area], applied to a Rational line, produces as breadth a fifth binomial.

Let AB be a line that is the side of a rational plus a medial [recta potens Rationale ac Medium], whose greater term is AC [Margin: a — I.45]; and to the Rational line DE let there be applied a rectangle DF equal to the square on AB, producing the breadth DG. I say that DG is a fifth binomial.

For let exactly the same things be done as in Proposition 61. Since the lines AC, CB, the components of AB — the side of a rational plus a medial — are incommensurable in square [Margin: b — X.41], making the sum of their squares Medial but the rectangle contained by them Rational, DK will be equal to the sum of the squares on the lines AC, CB and Medial, while LN is equal to the rectangle contained by AC, CB, and hence its double LF is Rational. Therefore the Medial DK, applied to the Rational line DE, produces a breadth DL that is Rational but incommensurable in length with the Rational DE [Margin: c — X.23]; whereas the Rational LF, applied to the Rational line LK, produces a breadth LG that is Rational and commensurable in length with LK — that is, with DE [Margin: d —

X.21]. Since, therefore, of the two lines DL, LG, the one is commensurable in length with the Rational DE while the other is incommensurable in length, DL, MG [recte: LG] will be incommensurable in length [Margin: e — X.13]. Therefore DL, LG are Rational lines commensurable in square only, and DG is a binomial [Margin: f — X.37].

Now, just as in Proposition 61, we shall show that the rectangle contained by DI, IL is equal to the square on LM; and, as in the preceding proposition, that DL is the greater term and is more powerful than LG by the square on a line incommensurable in length with itself. Therefore, since the lesser term LG has been shown commensurable in length with the assigned Rational line DE, DG will by the definition be a fifth binomial. Therefore the square on the side of a rational plus a medial, and so on. Which was to be shown.

Diagram. The construction for Proposition 65, identical in scheme. Left: the line B (top) / C (division) / A (foot). Right: the applied rectangle, upper edge D, I, L, M, G; base E, H, K, N, F.

- B / C / A: the side of a rational plus a medial, AB, divided at C into AC, CB
- D ... G (interior I, L, M): the breadth DG
- E ... F (base, feet H, K, N)
- DE (left side): the assigned Rational line

THEOR. 48. PROPOS. 66.

[Margin: lxv / lix]

The square on the side of two medials, applied to a Rational line, produces as breadth a sixth binomial.

Let AB be a line that is the side of two medials [bina Media potens], whose greater term is AC [Margin: a — I.45]; and to the Rational line DE let there be applied a rectangle DF equal to the square on AB, producing the breadth DG. I say that DG is a sixth binomial.

For with the same construction as in Proposition 61: since the lines AC, CB, the components of AB — the side of two medials — are incommensurable in square, and make both the sum of their squares Medial and the rectangle contained by them Medial, and this rectangle incommensurable with the sum of their squares [Margin: b — X.42], both DK, equal to that sum, and LF, equal to twice the rectangle contained by AC, CB, will be Medial. And since the Medials DK, LF are applied to the Rational line DE, their breadths DL, LG will be Rational but

incommensurable in length with DE [Margin: c — X.23]. Now since the sum of the squares on the lines AC, CB is incommensurable with the rectangle contained by AC, CB, while twice the rectangle contained by AC, CB is commensurable with that same rectangle contained by AC, CB — since the one is double the other [Margin: d — X.42] — the sum of the said squares, that is, DK, will be incommensurable with twice the rectangle contained by AC, CB [recte: CB], that is, with LF [Margin: e — X.13]. And consequently the lines DL, LG, together with DK, LF, are incommensurable in length [Margin: f — X.10]. They are therefore Rational lines commensurable in square only; and hence DG is a binomial [Margin: g — X.37].

Now, just as in the preceding proposition, we shall demonstrate that DL is the greater term and is more powerful than LG by the square on a line incommensurable in length with itself. Since, therefore, it has been shown that neither DL nor LG is commensurable in length with the assigned Rational line DE, DG will by the definition be a sixth binomial. Therefore the square on the side of two medials, applied to a Rational line, produces as breadth a sixth binomial. Which was to be shown.

Diagram. The construction for Proposition 66, identical in scheme. Left: the line B (top) / C (division) / A (foot). Right: the applied rectangle, upper edge D, I, L, M, G; base A, E, H, K, N, F.

- B / C / A: the side of two medials, AB, divided at C into AC, CB
- D ... G (interior I, L, M): the breadth DG
- E ... F (base, feet H, K, N)
- DE (left side): the assigned Rational line

Euclid, Book X (Clavius's Commentary) — the "commensurable-with" propositions and the composition of rational and medial areas

(Continuation of Book X on incommensurable magnitudes. Proposition numbers are given exactly as printed: the large Arabic "THEOR. / PROPOS." counters, together with the two divergent lowercase-roman margin numbers. In modern editions PROPOS. 67–72 correspond to Elements X.66–X.71.)

THEOR. 49. PROPOS. 67.

[Margin: lxvj. / lx.]

A straight line commensurable in length with a binomial [ex binis nominibus] is itself also a binomial, and of the same order.

Let AB be any binomial, divided into its terms, of which AC is the greater and CB the lesser; and let the straight line DE be commensurable in length with AB. I say that DE too is a binomial, and of the same order as AB.

[Margin: a — 12. sexti (Elements VI.12)] For let it be contrived that as the whole AB is to the whole DE, so is the part AC cut off to the part DF cut off. [Margin: b — 19. quin. (Elements V.19)] Then the remainder CB will also be to the remainder FE as the whole AB is to the whole DE. And since DE is assumed commensurable in length with AB, [Margin: c — 10. dec. (Elements X.10)] DF will be commensurable in length with AC, and FE with CB. [Margin: d — 37. dec. (Elements X.37)] But AC and CB, being the terms of a binomial, are rational; therefore DF and FE are rational as well.

Again, since AC is to DF as CB is to FE, then, alternando, AC is to CB as DF is to FE. Now AC and CB are commensurable in square only; [Margin: e — 10. dec. (Elements X.10)] therefore DF and FE too are commensurable in square only, [Margin: f — 37. dec. (Elements X.37)] and hence DE is a binomial.

I say also that it is of the same order as AB. For AC is greater than CB in square either by the square on a straight line commensurable with itself in length, or by the square on one incommensurable. If AC is greater than CB in square by the square on a straight line commensurable with itself in length, [Margin: g — 15. dec. (Elements X.15)] then DF too will be greater than FE in square by the square on a straight line commensurable with itself in length. And if AC is commensurable in length with the assigned rational, so that AB is a first binomial, [Margin: h — 12. dec. (Elements X.12)] then DF too will be commensurable in length with the same rational — since both the rational and DF are commensurable in length with the same AC. Therefore DE, by definition, is a first binomial; that is, of the same order. But if CB is commensurable in length with the assigned rational, so that AB is a second binomial, then in the same way FE too will be commensurable in length with the assigned rational; and therefore DE, by definition, is a second binomial. And if, finally, neither AC nor CB is commensurable in length with the assigned rational, so that AB is a third binomial, [Margin: i — 12. dec. (Elements X.12)] then neither DF nor FE will be commensurable in length with the assigned rational; and therefore DE, by definition, is a third binomial.

[Margin: k — 15. dec. (Elements X.15)] But if AC is greater than CB in square by the square on a straight line incommensurable with itself in length, then DF too will be greater than FE in square by the square on a straight line incommensurable with itself in length. Hence, as before, we shall show that DE is a fourth, fifth, or sixth binomial, according as AB has been a fourth, fifth, or sixth binomial. Therefore a line commensurable in length with a binomial, and so on. Which was to be proved.

Diagram. Two horizontal straight-line segments, one above the other, representing the binomial AB and the commensurable line DE, each divided into its two terms.

- A (upper line, left endpoint): start of the binomial AB
- C (upper line, mid-point): division into the terms AC (greater) and CB (lesser)
- B (upper line, right endpoint): end of AB
- D (lower line, left endpoint): start of the commensurable line DE
- F (lower line, mid-point): division into the parts DF and FE
- E (lower line, right endpoint): end of DE

SCHOLIVM.

If the straight line DE is commensurable in square only with AB, which is a binomial, we shall indeed show in the same way — provided that everywhere in the demonstration we substitute for "commensurable in length" the phrase "commensurable in square only" — that DE too is a binomial. But that it is of the same order as AB we shall by no means be able to conclude. For it does not follow, if the greater term AC is commensurable in length with the assigned rational, that the greater term DF is commensurable in length with the same; because it is not the case that both — namely the assigned rational and DF — are commensurable in length with the same AC, but only the rational is commensurable in length, whereas DF is commensurable in square only, by hypothesis. Indeed, if AB is a first, second, fourth, or fifth binomial, it is in no way possible that DE, being commensurable with it in square only, should be a binomial of the same order.

For let AB be a first, second, fourth, or fifth binomial, divided into its terms at C, and let DE be commensurable with it in square only. DE, as in the theorem, we shall show to be a binomial, divided into its terms at F, with the parts AC, CB proportional to the parts DF, FE — that is, the former have to the latter the same ratio as the whole AB has to the whole DE. I say it is in no way possible that DE be a binomial of the same order as AB. For if it were possible, let each be a first binomial.

Then each greater term, AC and DF, will by definition be commensurable in length with the assigned rational; [Margin: l — 12. dec. (Elements X.12)] and therefore they will be commensurable in length with one another. And since AC is to DF as AB is to DE, [Margin: m — 10. dec. (Elements X.10)] AB and DE will consequently be commensurable in length. But this is absurd, for DE was assumed commensurable in square only with AB. Therefore AB and DE are not both first binomials. In the same way, neither will they both be fourth binomials; nor yet both second or fifth. For then each lesser term, CB and FE, would by definition be commensurable in length with the assigned rational, and hence also with one another; and so the wholes AB, DE would be commensurable in length — which is not assumed.

Yet it is always true that, if AB is a first, second, or third binomial, the straight line DE commensurable with it in square only is likewise one of those three, though not of the same order. For, this being posited, AC will be greater than CB in square by the square on a straight line commensurable with itself in length. Since, then, AC is to CB as DF is to FE, [Margin: n — 15. dec. (Elements X.15)] DF too will be greater than FE in square by the square on a straight line commensurable with itself in length. Therefore, by definition, DE will be a first, second, or third binomial. In the same way, if AB is a fourth, fifth, or sixth binomial, so that AC is greater than CB in square by the square on a straight line incommensurable with itself in length, [Margin: o — 15. dec. (Elements X.15)] DF too will be greater than FE in square by the square on a straight line incommensurable with itself in length, since AC is to CB as DF is to FE. Therefore, by definition, DE will be a fourth, fifth, or sixth binomial as well, though not of the same order as AB.

In the following four propositions, however, DE will necessarily be of the same order as AB, even though it is commensurable with it in square only.

THEOR. 50. PROPOS. 68.

[Margin: lxvij. / lxi.]

A straight line commensurable in length with a bimedral [ex binis Mediis] is itself also a bimedral, and of the same order.

Let AB be any bimedral, divided into its terms, of which AC is the greater and CB the lesser, and let the straight line DE be commensurable in length with it. I say that DE too is a bimedral, and of the same order as AB.

[Margin: a — 12. sext. (Elements VI.12)] For let it be contrived that as the whole AB is to the whole DE, so is the part AC cut off to the part DF cut off. [Margin: b — 19. quin. (Elements V.19)] Then the remainder CB will also be to the remainder FE

as the whole AB is to the whole DE. And since DE is assumed commensurable in length with AB, [Margin: c — 10. dec. (Elements X.10)] DF will be commensurable in length with AC, and FE with CB. But AC and CB are medials; [Margin: d — 24. dec. (Elements X.24)] therefore DF and FE are medials too.

Again, since AC is to DF as CB is to FE, then, alternando, AC is to CB as DF is to FE. [Margin: e — 38. dec. (Elements X.38)] Now AC and CB are commensurable in square only; [Margin: f — 10. dec. (Elements X.10)] therefore DF and FE too are commensurable in square only. And since they have also been shown to be medials, DF and FE are medials commensurable in square only; [Margin: g — 38. vel 39. decimi (Elements X.38 or 39)] and therefore DE is a bimedral.

I say also that it is of the same order as AB. For since AC is to CB as DF is to FE, and as AC is to CB so is the square on AC to the rectangle contained by AC, CB, and as DF is to FE so is the square on DF to the rectangle contained by DF, FE — by lemma 3 of proposition 19 of this book — it will also hold that as the square on AC is to the rectangle contained by AC, CB, so is the square on DF to the rectangle contained by DF, FE; and, alternando, as the rectangle contained by AC, CB is to the rectangle contained by DF, FE, so is the square on AC to the square on DF; and, converting, as the square on AC is to the square on DF, so is the rectangle contained by AC, CB to the rectangle contained by DF, FE. But the square on AC is commensurable with the square on DF, since the straight lines AC, DF have been shown to be commensurable in length. [Margin: h — 10. dec. (Elements X.10)] Therefore the rectangle contained by AC, CB is also commensurable with the rectangle contained by DF, FE.

Hence, if the rectangle contained by AC, CB is rational, so that AB is a first bimedral, then the rectangle contained by DF, FE will also be rational, being commensurable with it; [Margin: i — 18. dec. (Elements X.18)] and so DE too will be a first bimedral. But if the rectangle contained by AC, CB is medial, so that AB is a second bimedral, then the rectangle contained by DF, FE will likewise be commensurable with it and medial, by the corollary of proposition 24 of this book; [Margin: k — 39. dec. (Elements X.39)] and therefore DE too will be a second bimedral. And so a line commensurable in length with a bimedral, and so on. Which was to be demonstrated.

Diagram. Two horizontal straight-line segments, one above the other, representing the bimedral AB and the commensurable line DE, each divided into its two terms.

- A (upper line, left endpoint): start of the bimedral AB

- C (upper line, mid-point): division into AC (greater) and CB (lesser)
- B (upper line, right endpoint): end of AB
- D (lower line, left endpoint): start of the commensurable line DE
- F (lower line, mid-point): division into DF and FE
- E (lower line, right endpoint): end of DE

SCHOLIVM.

In exactly the same way we shall prove that the straight line DE, if it is commensurable in square only with AB, which is a bimedral, is itself a bimedral and of the same order as the AB with which it is commensurable — provided only that everywhere, in place of "commensurable in length," we say throughout the demonstration "commensurable in square only," and so on, as is evident.

THEOR. 51. PROPOS. 69.

[Margin: lxviiij. / lxij.]

A straight line commensurable with a major [Maior] is itself also a major.

Let the major line AB be divided into its terms at C, and let DE be commensurable with it, whether in length and in square, or in square only. I say that DE too is a major. Let the same construction be made as before, so that the parts AC, CB have to the parts DF, FE the same ratio as the whole AB has to the whole DE. [Margin: a — 10. dec. (Elements X.10)] Since AC and CB are commensurable either in length and in square, or in square only, then AC, DF and CB, FE will be commensurable in the same way.

Again, since AC is to DF as CB is to FE, then, alternando, AC is to CB as DF is to FE; [Margin: b — 22. sexti (Elements VI.22)] therefore the square on AC is to the square on CB as the square on DF is to the square on FE; and, componendo, the sum of the squares on AC, CB is to the square on CB as the sum of the squares on DF, FE is to the square on FE; and, alternando, the sum of the squares on AC, CB is to the sum of the squares on DF, FE as the square on CB is to the square on FE. But the square on CB is commensurable with the square on FE, since the straight lines CB, FE have been shown to be commensurable either in length and in square, or in square only. [Margin: c — 10. dec. (Elements X.10)] Therefore the sum of the squares on the straight lines AC, CB is commensurable with the sum of the squares on the straight lines DF, FE. [Margin: d — 40. dec. (Elements X.40)] But that sum is rational, since the straight lines AC, CB compose the major AB. [Margin: e — 9. defin. (Elements X, definition 9)] Therefore this sum too is rational.

Again, since AC is to CB as DF is to FE; and as AC is to CB so is the square on AC to the rectangle contained by AC, CB, and as DF is to FE so is the square on DF to the rectangle contained by DF, FE, by lemma 3 of proposition 19 of this book; it will also hold that as the square on AC is to the rectangle contained by AC, CB, so is the square on DF to the rectangle contained by DF, FE; and, alternando, as the square on AC is to the square on DF, so is the rectangle contained by AC, CB to the rectangle contained by DF, FE. But the square on AC is commensurable with the square on DF, since the straight lines AC, DF have been shown to be commensurable either in length and in square, or in square only. [Margin: f — 10. dec. (Elements X.10)] Therefore the rectangle contained by AC, CB is commensurable with the rectangle contained by DF, FE. [Margin: g — 40. dec. (Elements X.40)] But the rectangle contained by AC, CB is medial; therefore the rectangle contained by DF, FE, being commensurable with it, is also medial, by the corollary of proposition 24 of this book.

And since AC is to CB as DF is to FE, [Margin: h — 40. dec. (Elements X.40)] and AC, CB are incommensurable in square — since they compose the major AB — [Margin: i — 10. dec. (Elements X.10)] DF, FE will also be incommensurable in square. And so, since DF, FE are incommensurable in square, and make the sum of their squares rational while the rectangle contained by them is medial, [Margin: k — 40. dec. (Elements X.40)] as has been shown, the whole DE is a major. Therefore a line commensurable with a major is itself also a major. Which was to be demonstrated.

Diagram. Two horizontal straight-line segments, one above the other, representing the major AB and the commensurable line DE, each divided into its two terms.

- A (upper line, left endpoint): start of the major AB
- C (upper line, mid-point): division into AC (greater) and CB (lesser)
- B (upper line, right endpoint): end of AB
- D (lower line, left endpoint): start of the commensurable line DE
- F (lower line, mid-point): division into DF and FE
- E (lower line, right endpoint): end of DE

THEOR. 52. PROPOS. 70.

[Margin: lxix. / lxij.]

A straight line commensurable with the side of a rational plus a medial [Rationale ac Medium potens] is itself also the side of a rational plus a medial.

Let AB be the side of a rational plus a medial, divided into its terms at C, and let DE be commensurable with it, whether in length and in square, or in square only. I say that DE too is the side of a rational plus a medial. For, the same construction being made as above, we shall show, as in the preceding proposition, that the sum of the squares on the straight lines AC, CB [Margin: a — 41. dec. (Elements X.41)] is commensurable with the sum of the squares on the straight lines DF, FE. But that sum is medial, since the straight lines AC, CB compose AB, the side of a rational plus a medial. Therefore, by the corollary of proposition 24 of this book, this sum too, being commensurable with it, is medial. In the same way, as in the same preceding proposition, the rectangle contained by AC, CB, [Margin: b — 41. dec. (Elements X.41)] which is rational, will be commensurable with the rectangle contained by DF, FE; and so the rectangle contained by DF, FE is rational as well, by definition 9. Finally, as in the same earlier proposition, DF, FE will be incommensurable in square. And so, since DF, FE are incommensurable in square, and make the sum of their squares medial while the rectangle contained by them is rational, as has been demonstrated, [Margin: c — 41. dec. (Elements X.41)] the whole DE is the side of a rational plus a medial. Therefore a line commensurable with the side of a rational plus a medial, and so on. Which was to be demonstrated.

Diagram. Two horizontal straight-line segments, one above the other, representing AB (the side of a rational plus a medial) and the commensurable line DE, each divided into its two terms.

- A (upper line, left endpoint): start of AB
- C (upper line, mid-point): division into AC (greater) and CB (lesser)
- B (upper line, right endpoint): end of AB
- D (lower line, left endpoint): start of DE
- F (lower line, mid-point): division into DF and FE
- E (lower line, right endpoint): end of DE

THEOR. 53. PROPOS. 71.

[Margin: lxx. / lxiv.]

A straight line commensurable with the side of two medials [bina Media potens] is itself also the side of two medials.

Let AB be the side of two medials, divided into its terms at C, and let DE be commensurable with it, whether in length and in square, or in square only. I say that DE too is the side of two medials. For, the same construction being made as above, we shall show, as in proposition 69, that the sum of the squares on the straight lines AC, CB [recte: AC, CB] is commensurable with the sum of the squares on the straight lines DF, FE, [Margin: a — 42. dec. (Elements X.42)] and also that the rectangle contained by AC, CB is commensurable with the rectangle contained by DF, FE. Since, then, both the sum of the squares on AC, CB and the rectangle contained by AC, CB are medial, by the corollary of proposition 24 of this book both the sum of the squares on DF, FE and the rectangle contained by DF, FE will also be medial. But DF, FE are incommensurable in square, as before.

Finally, [Margin: b — 42. dec. (Elements X.42)] since the sum of the squares on AC, CB and the rectangle contained by AC, CB are incommensurable — by hypothesis, because AB is the side of two medials — while the sum of the squares on DF, FE is commensurable with the sum of the squares on AC, CB, and the rectangle contained by DF, FE we have proved commensurable with the rectangle contained by AC, CB, by the scholium of proposition 14 of this book, the sum of the squares on DF, FE and the rectangle contained by DF, FE will likewise be incommensurable. And so, since the straight lines DF, FE are incommensurable in square, and make the sum of their squares medial, and the rectangle contained by them medial and incommensurable with the sum of their squares, [Margin: c — 42. dec. (Elements X.42)] DE is the side of two medials. And so a line commensurable with the side of two medials is itself also the side of two medials [recte: bina Media potens; source prints "ipsa Media potens"]. Which was to be proved.

Diagram. Two horizontal straight-line segments, one above the other, representing AB (the side of two medials) and the commensurable line DE, each divided into its two terms.

- A (upper line, left endpoint): start of AB
- C (upper line, mid-point): division into AC (greater) and CB (lesser)
- B (upper line, right endpoint): end of AB
- D (lower line, left endpoint): start of DE
- F (lower line, mid-point): division into DF and FE
- E (lower line, right endpoint): end of DE

THEOR. 54. PROPOS. 72.

[Margin: lxxi. / lxv.]

If a rational and a medial area are compounded, four irrational straight lines arise: either the binomial [ex binis nominibus], or the first bimedial [ex binis Mediis prima], or the major [Maior], or the side of a rational plus a medial [Rationale ac Medium potens].

Let AB be a rational area, with which the medial CD is compounded. I say that the straight line which is the side of the whole area AD [that is, whose square equals AD] is either a binomial, or a first bimedial, or a major, or the side of a rational plus a medial. For AB will be either greater than CD or less; equal it will not be, for otherwise, since AB is rational, CD too, being equal to it, would be rational — which is not assumed.

Let it first be the greater. [Margin: a — 45. primi (Elements I.45)] Let the rational EF be set out, and to it let there be applied the rectangle EG equal to AB, and to HG another rectangle HI equal to CD, so that the whole EI is equal to the whole AD. And since AB is rational and CD medial, EG too will be rational and HI medial; and since these are applied to the rational EF, [Margin: b — 21. dec. (Elements X.21)] EH will be rational and commensurable in length with EF, [Margin: c — 23. dec. (Elements X.23)] whereas HK will be rational but incommensurable in length with EF. Again, since EG, HI are incommensurable — as is clear from the definitions, because EG is rational while HI is irrational, namely medial — [Margin: d — 10. dec. (Elements X.10)] EH, HK, having the same ratio as they, will be incommensurable in length. Therefore EH, HK are rational and commensurable in square only; [Margin: e — 37. dec. (Elements X.37)] and hence EK is a binomial.

And since AB is assumed greater than CD, that is, EG greater than HI, EH will also be greater than HK; [Margin: f — 1. sexti (Elements VI.1)] for the rectangles EG, HI, being of the same height, are to one another as their bases EH, HK. Now the greater term EH will be greater in square than the lesser term HK either by the square on a straight line commensurable with itself in length, or by the square on one incommensurable. If EH is greater than HK in square by the square on a straight line commensurable with itself in length, then EK will be a first binomial, since the greater term EH has been shown commensurable in length with the rational EF. Therefore the straight line that is the side of the area EI — the area contained by the rational EF and the first binomial EK — and so also of the area AD, which is compounded of the rational AB and the medial CD, [Margin: g — 55. dec. (Elements X.55)] is the irrational called the binomial.

But if EH is greater than HK in square by the square on a straight line incommensurable with itself in length, then EK [recte: EK; source prints "EA"] will

be a fourth binomial, by definition, since the greater term EH has been shown commensurable in length with the rational EF. Therefore the straight line that is the side of the area EI — the area contained by the rational EF and the fourth binomial EK — and so also of the area AD, [Margin: h — 58. dec. (Elements X.58)] is the irrational called the major.

Next let AB be less than CD, and let the same construction be made as before. Then, as before, EK will be a binomial, and EH commensurable in length with EF. And since AB is less than CD, that is, EG less than HI, the straight line EH will also be less than HK. Therefore, again, HK, the greater term of EK (which is a binomial), will be greater in square than the lesser term EH either by the square on a straight line commensurable with itself in length, or by one incommensurable. If HK is greater than EH in square by the square on a straight line commensurable with itself in length, then EK will be a [first]...

Diagram. The construction for the case in which AB is greater than CD. On the left stand the two given areas (the rational AB and the medial CD) drawn as adjacent rectangles; on the right, the rectangle EI applied to the rational straight line EF, subdivided by a vertical into the rational part EG (equal to AB) and the medial part HI (equal to CD), with EK the resulting binomial breadth.

- A (left figure, top-left corner): rational area AB
- C (left figure, top, division point)
- B (left figure, bottom-left corner)
- D (left figure, bottom, division point)
- E (right figure, top-left corner): one end of the applied rectangle EI
- H (right figure, top, first division): boundary between EG and HI along the top edge (EH, HK)
- K (right figure, top-right corner): far end of the binomial breadth EK
- F (right figure, bottom-left corner): base of the rational line EF
- G (right figure, bottom, division): foot of the internal division (rectangles EG, HI)
- I (right figure, bottom-right corner): far end of the base

Diagram. The same construction redrawn for the case in which AB is less than CD (points relabelled identically). Two rectangles on the left for the given areas AB and CD; on the right, the rectangle EI applied to EF and subdivided into EG and HI, with breadth EK.

- A (left figure, top-left corner)

- C (left figure, top, division point)
- B (left figure, bottom-left corner)
- D (left figure, bottom, division point)
- E (right figure, top-left corner)

- K (right figure, top-right corner)
- F (right figure, bottom-left corner)
- G (right figure, bottom, division)
- I (right figure, bottom-right corner)

Book X — continuation

[Conclusion of THEOR. 54. PROPOS. 72 — from a rational and a medial area, four irrationals arise]

(Clavius's demonstration, continued from the preceding page.)

the second binomial, since EH, the lesser name, is commensurable in length with the rational EF, as was shown. Therefore the line which is potent in the area EI — the area contained by the rational EF and the second binomial EK — and hence also the area AD, composed of the rational AB and the medial CD, is irrational, and is called the first bimedial. [Margin: i 56. dec. — Elements X.56 (Clavius's numbering, one ahead of the received text; the reference is to the theorem that a rational times a second binomial yields the first bimedial)]

But if HK is potent by more than EH, by the square of a straight line incommensurable in length with itself, then EK, since EH — the lesser name shown — is commensurable in length with the rational EF, is the fifth binomial; and accordingly the line which is potent in the area EI, contained by the rational EF and the fifth binomial [EK], and thus also the area AD, [Margin: k 59. dec. — Elements X.59 (Clavius's numbering)] is irrational, and is called the [side] potent in a rational and a medial [i.e. the side of a rational plus a medial area]. If, therefore, a rational and a medial be placed together, four irrationals arise, and so on. Which was to be demonstrated.

THEOR. 55. PROPOS. 73. [Margin: Lxxii. / Lxvi.]

If two medials incommensurable with one another be composed, the two remaining irrationals arise — either the second bimedial, or the side potent in two medials.

(Euclid, Elements X.72; Clavius PROPOS. 73.)

Demonstration. Let two medials AB, CD, incommensurable with one another, be composed. I say that the line which is potent in the whole area AD is either the second binomial or the side potent in two medials. For again AB will be either greater than CD or less; it will certainly not be equal, for otherwise AB, CD would be commensurable — which is not supposed. Let it first be the greater, and let everything be done that was done in the preceding proposition. And since the areas AB, CD are supposed to be medial and incommensurable, the areas EG, HI will likewise be medial and incommensurable, since they are equal to them. [Margin: a 10. dec. — Elements X.10 (Clavius's numbering)] Therefore the straight lines EH, HK, which have the same ratio to those areas, are incommensurable in length; and each of them (since EG, HI are medial and are applied to the rational EF) [Margin: b 23. dec. — Elements X.23] is rational, being incommensurable in length with EF itself. EH, HK are therefore rational and commensurable in square only; [Margin: c 37. dec. — Elements X.37] and for that reason EK is a binomial. Now since AB is supposed greater than CD, then, as in the preceding proposition, EH will be the greater name of EK. It can therefore be potent by more than HK by the square of a straight line either commensurable or incommensurable with itself in length. If EH is potent by more than HK by the square of a straight line commensurable with itself in length, then, since each name EH, HK has been shown to be incommensurable in length with the rational EF, EK will by definition be the third binomial. Therefore the line which is potent in the area EI, contained by the rational EF and the third binomial EK — and hence also the area AD — [Margin: d 57. dec. — Elements X.57] is irrational, and is called the second binomial.

But if EH is potent by more than HK by the square of a straight line incommensurable with itself in length, then, since each name EH, HK is incommensurable in length [with the rational EF, EK will be] the sixth binomial, as is clear from the definition. The line, therefore, which is potent in the area EI, that is, in the area AD, [Margin: e 60. dec. — Elements X.60] is irrational, and is named the side potent in two medials.

But if AB be less than CD, we shall conclude the proposition in no other way, as is clear from the figure. Therefore, if two medials commensurable [recte: incommensurable] with one another be composed, the two remaining irrationals arise, and so on. Which was to be shown.

Diagram. The first of two paired figures for this proposition (the "greater" case, $EH > HK$). At the left, a square standing on base BD; at the right, a taller rectangle standing on base FI, divided by internal vertical lines.

- A (top-left corner of the left square): endpoint of the upper side
- C (point on the upper side of the left square): division of the top
- B (bottom-left corner of the left square): endpoint of the base
- D (point on the base of the left square): division of the base (BD)
- E (top-left corner of the right rectangle): endpoint of the upper side
- H (point on the upper side of the right rectangle): division of the top
- K (top-right corner of the right rectangle): endpoint of the upper side
- F (bottom-left corner of the right rectangle): endpoint of the base
- G (point on the base of the right rectangle): division of the base
- I (bottom-right corner of the right rectangle): endpoint of the base

Diagram. The second paired figure (the remaining cases), lettered identically to the first: a left square on base BD and a right rectangle on base FI.

- A (top-left corner of the left square)
- C (point on the upper side of the left square)
- B (bottom-left corner of the left square)
- D (point on the base of the left square)
- E (top-left corner of the right rectangle)
- H (point on the upper side of the right rectangle)
- K (top-right corner of the right rectangle)
- F (bottom-left corner of the right rectangle)
- G (point on the base of the right rectangle)
- I (bottom-right corner of the right rectangle)

COROLLARIUM.

From all this it is easily gathered that the line which arises from two names [the binomial], and the remaining irrational lines that follow it, are neither medial lines nor the same as one another.

For the square on a medial, applied to the rational line, [Margin: f 23. dec. — Elements X.23] produces as breadth a line incommensurable in length with the rational.

But the square on the binomial, applied to the rational, [Margin: g 61. dec. — Elements X.61] produces as breadth a first binomial.

And the square on the first bimedial, applied to the rational, [Margin: h 62. dec. — Elements X.62] produces as breadth a second binomial.

The square, next, on the second bimedral, applied to the rational, [Margin: i 63. dec. — Elements X.63] produces as breadth a third binomial.

But the square on the major, applied to the rational, [Margin: k 64. dec. — Elements X.64] produces as breadth a fourth binomial.

The square on the side potent in a rational and a medial, applied to the rational, [Margin: l 65. dec. — Elements X.65] produces as breadth a fifth binomial.

And lastly the square on the side potent in two medials, applied to the rational, [Margin: m 66. dec. — Elements X.66] produces as breadth a sixth binomial.

Therefore, since these breadths differ both from the breadth of the medial and from one another — from the breadth of the medial, because this one is rational whereas those are irrational; and from one another, because in order they are not the same binomials — it is clear that all the irrational lines discussed so far are different from one another.

SCHOLIUM.

So far Euclid has treated seven groups of six [senaries].

In the first, which is contained in propositions 37, 38, 39, 40, 41, and 42, he handed down the origin of six irrational lines: namely the binomial; the first bimedral; the second bimedral; the major; the side potent in a rational and a medial; and finally the side potent in two medials.

(Scholium, continued.)

In the second, which propositions 43, 44, 45, 46, 47, and 48 comprise, he treated their divisions, teaching that each single one can be divided at determinate points into its own names.

In the third, contained in propositions 49, 50, 51, 52, 53, and 54, he taught the finding of the six lines that are called binomials: namely the first, second, third, fourth, fifth, and sixth.

In the fourth, which propositions 55, 56, 57, 58, 59, and 60 complete, he showed how these six irrational lines, expounded in the first senary, differ from one another, teaching which irrational line is that which is potent in the area contained by the rational and the first binomial, or by the second, or the third, or the fourth, or the fifth, or the sixth binomial.

In the fifth, moreover, which you will find in propositions 61, 62, 63, 64, 65, and 66, he taught what breadths the squares of the irrational lines expounded in the first senary produce as irrationals when applied to the rational line.

In the sixth, which is completed in the five propositions 67, 68, 69, 70, and 71, he demonstrated that any line commensurable with one of the said six irrationals of the first senary is itself irrational, of the same kind as the one it is commensurable with.

In the seventh, finally, contained in two propositions — namely 72 and 73 — he set out once more a further difference among the six aforesaid irrationals.

Moreover, there is found in these six irrational lines, treated in the first senary, an Analogy or proportionality of the Arithmetic kind, which consists in an equal excess. The straight line that is the mean proportional, according to the Arithmetic Analogy, between the two names of any irrational line, is itself also irrational, of the same kind as the line between whose names it lies as mean.

For let any irrational line whatever — say the binomial AB, whose greater name is AC — be given, and let AB be bisected at D; and let E be taken equal to its half AD, or DB. I say that E is the mean, according to the Arithmetic Analogy, between AC and CB, and that it too is a binomial. For since AC exceeds the half AD by the straight line DC, and the half DB exceeds CB itself by the same straight line DC, it is clear that the half of AB — namely E — is the mean proportional between AC and CB in the Arithmetic Analogy.

Diagram. A straight line AB divided internally, with a shorter separate segment E drawn beneath it (equal to half of AB).

- A (left endpoint of the line): terminus of AB
- D (interior point): the midpoint of AB (bisection)
- C (interior point, between D and B): the division marking the greater name AC and lesser name CB
- B (right endpoint of the line): terminus of AB
- E (separate short segment below): equal to the half AD (= DB), the arithmetic mean between AC and CB

Again, since E is commensurable in length with the whole AB — for AB is its double — E too will be irrational, of the same kind as AB, as was demonstrated in the sixth senary.

We shall show that the same holds, in no other way, for the remaining irrational lines.

There now follow seven other senaries, in which Euclid demonstrates the same things concerning six other irrational lines, which are generated by subtraction, as we have shown that he demonstrated in the preceding seven senaries concerning the irrationals that arise by composition.

PRINCIPIVM SENARIORVM — per detractorem [The beginning of the senaries — by subtraction]

THEOR. 56. PROPOS. 74. [Margin: Lxxiii. / Lxviii.]

If from a rational a rational commensurable in square only with the whole be subtracted, the remainder is irrational. Let it be called an apotome.

(*Euclid, Elements X.73; Clavius PROPOS. 74.*)

Demonstration. Let there be subtracted from the rational AB a rational AC, commensurable in square only with AB itself. I say that the remainder BC is irrational. For since, by lemma 3 of proposition 19 of this book, as AB is to AC, so is the square on AB to the rectangle contained by AB, AC; and AB, AC are incommensurable in length; [Margin: a 10. dec. — Elements X.10] the square on AB and the rectangle contained by AB, AC will be incommensurable. But the square on AB is commensurable with the sum of the squares on AB, AC (for since AB, AC are supposed commensurable in square, the squares on AB, AC will be commensurable; [Margin: b 16. dec. — Elements X.16] therefore their sum too will be commensurable with the square on AB), while the rectangle contained by AB, AC is commensurable with twice that rectangle. Therefore the sum of the squares on AB, AC and twice the rectangle contained by AB, AC are incommensurable, as we demonstrated in the scholium of proposition 14 of this book. [Margin: c 7. sec. — Elements II.7] Now the sum of the squares on AB, AC is equal to twice the rectangle under AB, AC together with the square on BC. Therefore the sum of the squares on AB, AC is, by the corollary of proposition 17 of this book, incommensurable with the remaining square on BC. Since, then, the sum of the squares on AB, AC is rational (because it is commensurable with the rational square on AB, described on the rational line), the square on BC will be irrational, and accordingly the straight line BC itself will be irrational. Let it be called an apotome. The more recent writers call it a residual. If, therefore, from a rational a rational commensurable in square only with the whole be subtracted, the remainder is irrational, and so on. Which was to be shown.

Diagram. A straight line AB divided at C; BC is the apotome (remainder).

- A (left endpoint): terminus of the whole line AB
- C (interior division point): marks off the subtracted rational AC
- B (right endpoint): terminus of AB; BC is the remaining apotome

SCHOLIUM.

Euclid could also have proposed this proposition in the following way.

If from the greater name of a binomial the lesser name be subtracted, the remainder is irrational. Let it be called an apotome.

For since AB, AC are rational and commensurable in square only, the line composed of them is irrational — it is called a binomial, whose greater name is AB and lesser name is AC. [Margin: d 37. dec. — Elements X.37] Therefore AC, the lesser name, is subtracted from the greater name AB, so that the apotome BC is left.

Diagram. A straight line AB divided at C (the scholium's figure for the apotome).

- A (left endpoint): terminus of AB
- C (interior division point): the point of subtraction
- B (right endpoint): terminus of AB; BC is the apotome

THEOR. 57. PROPOS. 75. [Margin: Lxxiiii. / Lxix.]

If from a medial a medial commensurable in square only with the whole be subtracted, such that it contains with the whole a rational [rectangle], the remainder is irrational. Let it be called the first apotome of a medial.

(Euclid, Elements X.74; Clavius PROPOS. 75.)

Demonstration. Let there be subtracted from the medial AB a medial AC, commensurable in square only with AB itself, and let the rectangle contained by AB, AC be rational. I say that the remainder BC is irrational. For since AB, AC are commensurable in square, the squares on AB, AC will be commensurable, [Margin: a 16. dec. — Elements X.16] and hence their sum too will be commensurable with the square on AC. But the square on AC is medial, irrational, and a medial [area]. Therefore, by the corollary of proposition 24 of this book, the sum of the squares on AB, AC will also be irrational and medial. And since the rectangle contained by AB, AC is supposed rational, twice the rectangle under AB, AC will also be rational. Therefore the sum of the squares on AB, AC is incommensurable with twice the rectangle under AB, AC. [Margin: b 7. sec. —

Elements II.7] Since, then, the sum of the squares on AB, AC is equal to twice the rectangle under AB, AC together with the square on BC, twice the rectangle under AB, AC together with the square on BC will also be incommensurable with twice the rectangle under AB, AC. [Margin: c 17. dec. — Elements X.17] Therefore twice the rectangle under AB, AC and the square on BC are also incommensurable. Since, then, twice the rectangle under AB, AC is rational, the square on BC will be irrational; and hence the straight line BC too will be irrational. Let it be called the first apotome of a medial, because, namely, it is what is left after subtracting the lesser name of the first bimedral line from the greater name, as will be made clear in the following scholium. If, therefore, from a medial a medial commensurable in square only with the whole be subtracted, such that it contains with the whole a rational [rectangle], the remainder is irrational. Let it be called the first apotome of a medial. Which was to be shown.

Diagram. A straight line AB divided at C; BC is the first apotome of a medial.

- A (left endpoint): terminus of the whole medial AB
- C (interior division point): marks off the subtracted medial AC
- B (right endpoint): terminus of AB; BC is the first apotome of a medial

SCHOLIUM.

This proposition could also have been proposed in the following way.

If from the greater name of the first bimedral the lesser name be subtracted, the remainder is irrational. Let it be called the first apotome of a medial.

For since AB, AC are medials commensurable in square only, and contain a rational [rectangle], the line composed of them will be irrational — it is called the first bimedral, whose greater name is AB and lesser name is AC. [Margin: d 38. dec. — Elements X.38] Therefore AC, the lesser name, is subtracted from the greater name AB, so that BC, the first apotome of a medial, is left.

THEOR. 58. PROPOS. 76. [Margin: Lxxv. [?] / Lxx.]

If from a medial a medial commensurable in square only with the whole be subtracted, such that it contains with the whole a medial [rectangle], the remainder is irrational. Let it be called the second apotome of a medial.

(Euclid, Elements X.75; Clavius PROPOS. 76.)

Demonstration. Let there be subtracted from the medial AB a medial AC, commensurable in square only with AB itself, and let the rectangle contained by AB, AC be medial. I say that the remainder BC is irrational. For since the squares on AB, AC are commensurable, being commensurable in square, [Margin: a 16. dec. — Elements X.16] their sum too will be commensurable with each of them. But each of them is medial, since the straight lines AB, AC are supposed medial. Therefore their sum too, commensurable with each of them, is medial, by the corollary of proposition 24 of this book. Again, since the rectangle under AB, AC is supposed medial, its double also — namely twice the rectangle under AB, AC — will be medial, by the corollary of proposition 24 of this book. [Margin: b 7. sec. — Elements II.7] Since, then, the sum of the squares on AB, AC is equal to twice the rectangle under AB, AC together with the square on BC, the sum of the squares on AB, AC — which is medial — will exceed twice the rectangle under AB, AC — which is also medial — by the square on BC. But a medial does not exceed a medial by a rational [area]. [Margin: c 67. dec. — Elements X.26 (Clavius's numbering; the tabulated figure "67" appears to be a misprint or misreading — see anomaly note)] Therefore the square on BC is not rational. It is therefore irrational, and the straight line BC itself is irrational. Let it be called the second apotome of a medial, because it is what is left after subtracting the lesser name of the second binomial from the greater name, as will appear from the following scholium. If, therefore, from a medial a medial be subtracted, and so on. Which was to be shown.

Diagram. A straight line AB divided at C; BC is the second apotome of a medial.

- A (left endpoint): terminus of the whole medial AB
- C (interior division point): marks off the subtracted medial AC
- B (right endpoint): terminus of AB; BC is the second apotome of a medial

SCHOLIUM.

This theorem too could have been proposed in the following way.

If from the greater name of the second binomial the lesser name be subtracted, the remainder is irrational. Let it be called the second apotome of a medial.

For since AB, AC are medials commensurable in square only, and contain a medial [rectangle], the line composed of them will be irrational — it is called the second binomial, whose greater name is AB and lesser name is AC. [Margin: d 39. dec. — Elements X.39] Therefore AC, the lesser name, is subtracted from the greater name AB, so that BC, the second apotome of a medial, is left.

THEOR. 59. PROPOS. 77. [Margin: Lxxvi. / Lxxi.]

If from a straight line a straight line incommensurable in square with the whole be subtracted, such that it makes with the whole the sum of the squares on them rational, but the [rectangle] contained by them medial, the remainder is irrational. Let it be called the minor.

(*Euclid, Elements X.76; Clavius PROPOS. 77.*)

Let AC, a straight line incommensurable in square with the whole AB, be subtracted from the straight line AB; and let the sum of the squares on AB and AC be rational, but the rectangle contained by AB and AC medial. I say that the remainder BC is irrational.

Diagram. A single straight line divided at one interior point. The line runs from A on the left to B on the right, with C marked between them (nearer B), so that AC is the part subtracted and CB the remainder.

- A (left endpoint): the whole line AB begins here
- C (interior point): the point of subtraction
- B (right endpoint): AB is the whole; AC the subtracted part; BC the remainder

For the sum of the squares on AB and AC is rational, whereas the rectangle contained by AB and AC — and hence also, by the corollary to Proposition 24 of this book, the quantity commensurable with it, namely twice the rectangle contained by AB and AC — is medial, that is, irrational. [Margin: a — Elements X.10] Therefore the sum of the squares on AB and AC [recte: is incommensurable with twice the rectangle contained by AB and AC — the predicate is dropped in the print, evidently by eye-skip on the repeated phrase "the rectangle under AB, AC"; supplied from the parallel demonstration of Prop. 78]. [Margin: b — Elements II.7] Now the sum of the squares on AB and AC [recte: is equal to twice the rectangle contained by AB and AC — likewise dropped by eye-skip] together with the square on BC. Therefore, by the corollary to Proposition 17 of this book, the sum of the squares on AB and AC is incommensurable with the remaining square on BC as well. But the sum of the squares on AB and AC is assumed to be rational. [Margin: c — Elements X, Def. 10] Therefore the square on BC, being incommensurable with it, is irrational, and so is the line BC. Let it be called the **minor**, since it is left over, after the subtraction, as the line of lesser name subtracted from the greater — as we shall explain in the following scholium. So then, if from a straight line a straight line be subtracted, and so on. Which was to be demonstrated.

SCHOLIUM

This theorem could also have been stated in the following way.

If from the greater name of the greater line the lesser name be subtracted, the remainder is irrational. Let it be called the **minor**.

*For since AB and AC are incommensurable in square, and make the sum of their squares rational but the rectangle contained by them medial, [Margin: d — Elements X, Def. 40] the line composed of them will be the irrational which is called the **major***, its greater name being AB and its lesser AC. Therefore AC, the lesser name, is subtracted from the greater AB, so that the* **minor** BC is left over.*

THEOR. 60. PROPOS. 78.

[Margin: Lxxvii. / Lxxii.]

If from a straight line there be subtracted a straight line incommensurable in square with the whole, which with the whole makes the sum of the squares on them medial but the rectangle contained by them rational, the remainder is irrational. Let it be called **that which produces with a rational area a medial whole**. (Euclid X.77.)

Let AC be subtracted from the straight line AB, incommensurable in square with AB; and let the sum of their squares be medial, but the rectangle contained by them rational. I say that the remainder BC is irrational.

Diagram. The same construction: a straight line from A (left) to B (right), divided at C between them.

- A (left endpoint)
- C (interior point of subtraction)
- B (right endpoint): AB whole, AC subtracted, BC remainder

For the sum of the squares on AB and AC is medial, that is, irrational, whereas the rectangle taken twice under AB and AC is rational. [Margin: a — Elements X, Def. 10] Therefore the sum of the squares on AB and AC is incommensurable with twice the rectangle contained by AB and AC. [Margin: b — Elements II.7] Now the sum of the squares on AB and AC is equal to twice the rectangle contained by AB and AC together with the square on BC. Therefore twice the rectangle contained by AB and AC, together with the square on BC, is incommensurable with twice the rectangle contained by AB and AC. [Margin: c — Elements X.17] Twice the

rectangle contained by AB and AC and the square on BC are therefore incommensurable. Since, then, twice the rectangle contained by AB and AC is rational, [Margin: d — Elements X, Def. 10] the square on BC will be irrational, and so the line BC is irrational. Let it be called **that which produces with a rational area a medial whole**, because its square, added to twice the rectangle contained by AB and AC (which is rational), makes the whole sum of the squares on AB and AC, which is medial. So then, if from a straight line a straight line be subtracted incommensurable in square with the whole, which with the whole makes the sum of their squares medial but the rectangle contained by them rational, the remainder is irrational, and so on. Which was to be shown.

SCHOLIUM

Euclid could also have stated this theorem in this manner.

If from the greater name of the line that is capable of a rational and a medial area the lesser name be subtracted, the remainder is irrational. Let it be called **that which produces with a rational area a medial whole**.

*For since AB and AC are incommensurable in square, and make the sum of their squares medial but the rectangle contained by them rational, [Margin: e — Elements X, Def. 41] the line composed of them will be the irrational which is named the line **capable of a rational and a medial area***, its greater name being AB and its lesser AC. Therefore the lesser name AC is subtracted from the greater AB, so that BC is left over as the line which produces with a rational area a medial whole.**

THEOR. 61. PROPOS. 79.

[Margin: Lxxviii. / Lxxiii.]

If from a straight line there be subtracted a straight line incommensurable in square with the whole, which with the whole makes both the sum of the squares on them medial and the rectangle contained by them medial, and this rectangle also incommensurable with the sum of their squares, the remainder is irrational. Let it be called **that which produces with a medial area a medial whole**. (Euclid X.78.)

Let AC be subtracted from the straight line AB, incommensurable in square with AB; and let both the sum of their squares and the rectangle contained by them be

medial, and let this rectangle be incommensurable with the sum of their squares. I say that the remainder BC is irrational.

Diagram. Again a straight line from A (left) to B (right), divided at C between them.

- A (left endpoint)
- C (interior point of subtraction)
- B (right endpoint): AB whole, AC subtracted, BC remainder

[Margin: a — Elements II.7] For since the sum of the squares on AB and AC is equal to twice the rectangle contained by AB and AC together with the square on BC, the sum of the squares on AB and AC — which is assumed medial — will exceed twice the rectangle contained by AB and AC (which, by the corollary to Proposition 24 of this book, is likewise medial, since it is commensurable with the medial rectangle contained by AB and AC) by the square on BC. [Margin: b — Elements X.27] But a medial does not exceed a medial by a rational area. Therefore the square on BC is not rational; hence it is irrational, and the line BC itself is irrational. Let it be called **that which produces with a medial area a medial whole**, because its square, together with the rectangle contained by AB and AC (which is medial), makes the whole sum of the squares on AB and AC, which is likewise medial. So then, if from a straight line a straight line be subtracted, and so on. Which was to be shown.

SCHOLIUM

This theorem could also have been proposed in the following way.

If from the greater name of the line capable of two medial areas the lesser name be subtracted, the remainder is irrational. Let it be called **that which produces with a medial area a medial whole**.

*Since AB and AC are incommensurable in square, and make both the sum of their squares medial and the rectangle contained by them medial, this rectangle being incommensurable with the sum of their squares, the line composed of them will be the irrational which is called **capable of two medial areas***, its greater name being AB and its lesser AC. Therefore the lesser name AC is subtracted from the greater AB, so that BC is left over as the line which produces with a medial area a medial whole.**

LEMMA

If the same excess lie between the first magnitude and the second as between the third magnitude and the fourth, then conversely there will also be the same excess between the first magnitude and the third as between the second magnitude and the fourth.

Let there be four magnitudes AB, CD, EF, GH, and let IB, the excess between AB and CD, be equal to the excess KF, between EF and GH. I say that the excess between AB and EF is the same as that between CD and GH.

Diagram. Four horizontal line segments arranged one above another :

- A——I—B: segment AB, marked at I (so IB is the excess of AB over its equal-to-CD part AI)
- C——D: segment CD
- E——K—F: segment EF, marked at K (so KF is the excess of EF over its equal-to-GH part EK)
- G——H: segment GH

For since IB is the excess between AB and CD, AI will be equal to CD. In the same way EK will be equal to GH. The same excess, then, will lie between AI and EK as between CD and GH, since these magnitudes are equal to those, each to each. But the excess between the wholes AB and EF is, by the sixteenth common notion of Book I, the same as the excess between AI and EK — because IB and KF are assumed equal. Therefore the same excess will also lie between AB and EF as between CD and GH. Which was proposed.

COROLLARIUM

From this it is clear that four magnitudes having an arithmetical proportion also have, alternately, an arithmetical proportion. For a proportion of this kind consists in the same excess, which we have shown to be the same between the first and third magnitudes as is found between the second and fourth, provided the excess between the first magnitude and the second is the same as that between the third magnitude and the fourth — that is, provided the four magnitudes have an arithmetical proportion.

THEOR. 62. PROPOS. 80.

[Margin: Lxxix. / Lxxiv.]

To an apotome there can be annexed only one rational straight line that is commensurable in square only with the whole. (Euclid X.79.)

Let AB be an apotome, and let the rational line BC, commensurable in square only with the whole AC, be annexed to it. I say that no other rational line can be annexed to AB which is commensurable in square only with the whole. For if it be possible, let another rational line BD be annexed, such that BD is commensurable in square only with AD.

Diagram. A single straight line carrying four marked points. From the left: A, then B (about midway), then C and D close together at the right.

- A (left endpoint)
- B (interior point): AB is the apotome
- C: BC is the annexed rational line, so AC is the whole
- D (right endpoint, near C): BD is the supposed second annex, so AD is the whole in that case

And since BC is rational, AC will be rational and commensurable in square only with it. AC and BC are therefore rationals commensurable in square only. In the same way AD and BD will be rationals commensurable in square only. Now the same excess lies between the sum of the squares on AC and BC and twice the rectangle contained by AC and BC as lies between the sum of the squares on AD and BD and twice the rectangle contained by AD and BD. (For the sum of the squares on AC and BC exceeds twice the rectangle contained by AC and BC by the square on AB, [Margin: a — Elements II.7] since the sum of the squares on AC and BC is equal to twice the rectangle contained by AC and BC together with the square on AB. And in the same way the sum of the squares on AD and BD exceeds twice the rectangle contained by AD and BD by the same square on AB, [Margin: b — Elements II.7] since the sum of the squares on AD and BD is likewise equal to twice the rectangle contained by AD and BD together with the square on AB.) Therefore, alternately, by the preceding lemma, the same excess will lie between the sum of the squares on AC and BC and the sum of the squares on AD and BD as lies between twice the rectangle contained by AC and BC and the rectan-

gle taken twice under AD and DB. But the excess between those sums is a rational area, by the scholium to Proposition 27 of this book, since each of them is rational. (For since AC and BC are rationals commensurable in square only, their squares will be rational and commensurable; [Margin: c — Elements X.16] therefore the sum composed of them is commensurable with each of them, and hence also rational, by Definition 9. In no other way shall we show that the sum

of the squares on AD and BD is rational.) Therefore the excess between twice the rectangle contained by AC and BC and twice the rectangle contained by AD and BD is also a rational area. [Margin: d — Elements X.22] And since the rectangle contained by AC and BC — rationals commensurable in square only — is medial, then by the corollary to Proposition 24 of this book its double as well, namely twice the rectangle contained by AC and BC, is medial. By the same reasoning twice the rectangle contained by AD and BD is medial. [Margin: e — Elements X.27] But a medial does not exceed a medial by a rational area. Therefore the excess between twice the rectangle contained by AC and BC and twice the rectangle contained by AD and BD is not a rational area. Yet it was shown to be rational. Which is absurd. Therefore no other rational line can be annexed to AB except BC, which is commensurable in square only with the whole. To an apotome, then, only one can be annexed, and so on. Which was to be shown.

THEOR. 63. PROPOS. 81.

[Margin: Lxxx. / Lxxv.]

To a first apotome of a medial there can be annexed only one medial straight line that is commensurable in square only with the whole and contains with the whole a rational area. (Euclid X.80.)

Let AB be a first apotome of a medial, and let BC, a medial commensurable in square only with the whole AC, be annexed to it, and let the rectangle contained by AC and BC be rational. I say that no other medial can be annexed to AB which is commensurable in square only with the whole and contains with the whole a rational area. For if it be possible, let another medial BD be annexed, commensurable in square only with the whole AD, and let the rectangle contained by AD and BD be rational.

Diagram. A single straight line with four marked points. From the left: A, then B, then C and D close together at the right.

- A (left endpoint)
- B (interior point): AB is the first apotome of a medial
- C: BC is the annexed medial, AC the whole
- D (right endpoint, near C): BD the supposed second annex, AD the whole

And since BC is a medial commensurable in square only with AC, [Margin: a — Elements X.24] AC too will be medial, since it is commensurable with it. AC and BC are therefore medials commensurable in square only. Now the same excess lies between the sum of the squares on AC and CB and the sum of the squares on

AD and BD as lies between twice the rectangle contained by AC and BC and twice the rectangle contained by AD and BD, as was shown in the preceding proposition.

Diagram. The same divided line repeated beside the demonstration : A (left), B, then C and D together at the right.

- A (left endpoint); B (apotome point); C; D (right endpoint)

But the excess between these rectangles is, by the scholium to Proposition 27 of this book, a rational area, since each of them is rational. (For since the rectangle contained by AC and BC is assumed rational, twice the rectangle contained by AC and BC, being commensurable with it, will be rational; and by the same reasoning twice the rectangle contained by AD and BD will be rational. Therefore the excess between the sum of the squares on AC and BC and the sum of the squares on AD and BD is a rational area.) And since the straight lines AC and BC are medials commensurable in square only, their squares too will be medial and commensurable. [Margin: b — Elements X.16] Therefore the sum composed of them is commensurable with each of them, and hence medial, by the corollary to Proposition 24 of this book. In no other way, likewise, the sum of the squares on AD and BD will be medial. [Margin: c — Elements X.27] But a medial does not exceed a medial by a rational area. Therefore the excess between the sum of the squares on AC and BC and the sum of the squares on AD and BD is not a rational area. Yet it was shown to be rational. Which is absurd. Therefore no other medial can be annexed to AB except BC, which is commensurable in square only with the whole and contains with the whole a rational area. To a first apotome of a medial, then, only one can be annexed, and so on. Which was to be demonstrated.

THEOR. 64. PROPOS. 82.

[Margin: Lxxxi. / Lxxvi.]

To a second apotome of a medial there can be annexed only one medial straight line that is commensurable in square only with the whole and contains with the whole a medial area. (Euclid X.81.)

Let AB be a second apotome of a medial, and let the medial BC, commensurable in square only with the whole AC, be annexed to it, and let the rectangle contained by AC and BC be medial. I say that no other medial can be annexed to AB which is commensurable in square only with the whole and contains with the whole a medial area. For if it be possible, let another medial BD be annexed to it,

commensurable in square only with the whole AD, and let the rectangle contained by AD and BD be medial.

Let a rational line EF be set out, [Margin: a — Elements I.45] to which let there be applied the rectangle EG equal to the sum of the squares on AC and BC; and to the same EF let another, EI, be applied equal to the square on AB; and finally another, EL, equal to the sum of the squares on AD and BD.

Diagram. A single straight line with four marked points, above the rectangle figure : A, B (close together at the left), then C and D together at the right.

- A (left endpoint); B; C; D (right endpoint) — the second apotome of a medial AB, its annex BC, whole AC, and the supposed second annex BD with whole AD

Diagram. A large rectangle standing on the rational line EF (its left, vertical side), divided into strips by vertical lines. The upper edge carries, from left to right, the labels E, K, H, M; the lower edge carries, from left to right, F, I, G, L. The successive rectangles applied to EF represent the areas named in the text.

- E (upper-left corner) / F (lower-left corner): the exposed rational line EF is the vertical left side
- K (upper edge, just right of E) / I (lower edge): the rectangle EI is equal to the square on AB
- H (upper edge) / G (lower edge): the rectangle EG is equal to the sum of the squares on AC and BC; KH is equal to twice the rectangle contained by AC and BC
- M (upper-right corner) / L (lower-right corner): the rectangle EL is equal to the sum of the squares on AD and BD; ML is equal to twice the rectangle contained by AD and BD

[Margin: b — Elements II.7] Since, then, the sum of the squares on AC and BC is equal to twice the rectangle contained by AC and BC together with the square on AB, KH will be equal to that which is contained twice under AC and BC. In the same way ML will be equal to that which is contained twice under AD and BD. And since AC and BC are medials, and commensurable in square (for since BC is assumed medial, [Margin: c — Elements X.24] AC too will be commensurable with it in square, and medial), their squares will be medial and commensurable. [Margin: d — Elements X.16] Therefore the sum composed of them is commensurable with each of them, and consequently medial, by the corollary to Proposition 24 of this book. Therefore EG also, being equal to that sum, is medial; and when it is applied to the rational line EF, [Margin: e — Elements VI.23] EH

will be rational but incommensurable in length with EF. Again, since the rectangle contained by AC and BC is medial, its double as well — namely KG — will be medial, by the corollary to Proposition 24 of this book; and when this is applied to the rational line KI, [Margin: f — Elements X.23] KH will be rational but incommensurable in length with KI, that is, with EF. And since AC and BC are incommensurable in length, and as AC is to BC, so is the square on AC to the rectangle contained by AC and BC, as we showed in the third lemma to Proposition 19 of this book, [Margin: g — Elements X.10] the square on AC will be incommensurable with the rectangle contained by AC and BC. But the sum of the squares on AC and BC — that is, the rectangle EG — is commensurable with the square on AC. (For since the straight lines AC and BC are assumed commensurable in square, their squares too will be commensu-

commensurable. Therefore the sum composed of them is also commensurable with each of them — namely, with the square on AC.) [Margin: h — X.16] And its double, namely KG, is commensurable with the rectangle contained by AC, BC. Therefore EG is incommensurable with KG, from what we taught in the scholium to Prop. 14 of this book. The straight lines EH, KH, then, since they have the same ratio as EG, KG, are incommensurable in length [Margin: i — X.10]; but they were also shown to be rational. Therefore they are rational lines commensurable in square only. Hence, since from the rational line EH there is subtracted the rational line KH, commensurable in square only with EH, EK will be an apotome [Margin: k — X.74], and KH the annex [congruens] congruent with it. In just the same way we shall prove that EK is an apotome and that KM is congruent with it. It would follow, then, that more than one straight line — a rational line commensurable in square only with the whole — joins the apotome, which is absurd; for it was demonstrated [Margin: l — X.80] that only one joins. Therefore to the second apotome of a medial only one straight line joins, etc. Which was to be demonstrated.

THEOR. 65. PROPOS. 83.

[Margin: LXXXII. / LXXVII.]

To a minor line only one straight line joins that is incommensurable in square with the whole, and that makes with the whole a sum composed of their squares which is rational, while what is contained by them is medial.

Let AB be a minor line, and let BC, congruent [annexed] to it, be incommensurable in square with the whole AC, making the sum of the squares

on AC, BC rational, while the rectangle contained by AC, BC is medial. I say that no other line joins AB which does the same. For, if it can be done, let another line BD join it, incommensurable in square with the whole AD, making the sum of the squares on AD, BD rational, and the rectangle contained by AD, BD medial. Now, as was demonstrated in Prop. 80, the excess between the sum of the squares on AC, BC and the sum of the squares on AD, BD is the same as the excess between twice the rectangle on AC, BC and twice the rectangle on AD, BD. But the excess between those sums is a rational area — by the scholium to Prop. 27 of this book — since each of them is assumed rational. Therefore the excess between twice the rectangle on AC, BC and twice the rectangle on AD, BD is also a rational area — yet it is likewise non-rational. (For, since the rectangle contained by AC, BC is assumed medial, its double, namely twice the rectangle on AC, BC, will be medial; and in the same way twice the rectangle on AD, BD will be medial [Margin: a — X.27]; and so the one cannot exceed the other by a rational area.) This is absurd. Therefore no other line besides BC joins AB incommensurable in square with the whole, etc. To a minor line, then, only one joins, etc. Which was to be demonstrated.

Diagram. A single horizontal straight line for Prop. 83, with marked division points reading left to right A, B, C, D. AB is the minor line and BC its annex, so that AC is the whole; BD is the alternative annex, giving the whole AD.

- A (left end): start of the line
- B (interior): division marking the annex BC / BD
- C (interior): end of the first whole AC
- D (right end): end of the alternative whole AD

THEOR. 66. PROPOS. 84.

[Margin: LXXXIII. / LXXVIII.]

To the line which with a rational area makes the whole medial, only one straight line joins that is incommensurable in square with the whole, and that makes with the whole a sum composed of their squares which is medial, while what is contained by them is rational.

Let AB be the line which with a rational area makes the whole medial, and let BC be congruent [annexed] to it, incommensurable in square with the whole AC, making the sum of the squares on AC, BC medial, but the rectangle contained by AC, BC rational. I say that no other straight line joins AB which produces these same things. For, if it can be done, let another line BD join it, incommensurable in

square with the whole AD, making the sum of the squares on AD, BD medial, but the rectangle contained by AD, BD rational. Now, as was shown in Prop. 80, the excess between the sum of the squares on AC, BC and the sum of the squares on AD, BD is the same as the excess between twice the rectangle on AC, BC and twice the rectangle on AD, BD. But the excess between these rectangles is a rational area, as we demonstrated in Prop. 81. Therefore the excess between those sums is also non-rational, since each of them is medial [Margin: a — X.27] — for one medial cannot exceed another medial by a rational area. This is absurd. Therefore no other line than BC joins AB incommensurable in square with the whole, etc. Hence to the line which with a rational area makes the whole medial, only one joins, etc. Which was to be demonstrated.

Diagram. A single horizontal straight line for Prop. 84, with division points left to right A, B, C, D. AB is the given line and BC its annex (whole AC); BD is the alternative annex (whole AD).

- A (left end): start of the line
- B (interior): division for the annex BC / BD
- C (interior): end of the whole AC
- D (right end): end of the alternative whole AD

THEOR. 67. PROPOS. 85.

[Margin: LXXXIV. / LXXIX.]

To the line which with a medial area makes the whole medial, only one straight line joins that is incommensurable in square with the whole, and that makes with the whole both the sum composed of their squares medial, and what is contained by them medial and incommensurable with the sum composed of their squares.

Let AB be the line which with a medial area makes the whole medial, and let BC be congruent [annexed] to it, incommensurable in square with the whole AC, making the sum of the squares on AC, BC medial, and the rectangle contained by AC, BC [medial], incommensurable with the sum of the squares on AC, BC. I say that no other straight line joins AB which produces these same things. For, if it can be done, let another line BD join it, incommensurable in square with the whole AD, so that the sum of the squares on AD, BD is medial, and the rectangle contained by AD, BD is medial too, and [incommensurable with] the sum of the squares on AD, BD. Now, the same construction being made as in Prop. 82: since the sum of the squares on AC, BC is medial [Margin: a — X.23], EG too will be

equal to it and medial. Again, since the rectangle contained by AC, BC is medial, its double KG will also be medial [Margin: b — X.23]. Therefore the straight line KH is rational, but incommensurable in length with EF. And since KG is commensurable with the rectangle contained by AC, BC (being its double), while the rectangle contained by AC, BC is assumed incommensurable with the sum of the squares on AC, BC, KG too will be incommensurable [Margin: c — X.14] with that same sum — that is, with EG — and therefore the straight lines EH, KH, having the same ratio as EG, KG, are incommensurable in length [Margin: d — X.10]. But they were also shown to be rational. Therefore they are rational lines commensurable in square only. Hence, since from the rational line EH the rational line KH, commensurable in square only with EH, is subtracted, EK will be an apotome [Margin: e — X.74], and KH its annex, congruent with it. In just the same way we shall show that EK is an apotome, and that KM is its congruent annex. Therefore not only one straight line joins the apotome, etc.; which is absurd, since it was demonstrated [Margin: f — X.80] that only one joins. Therefore to the line which with a medial area makes the whole medial, only one joins, etc. Which was to be shown.

Diagram. Two figures for Prop. 85. Above is a horizontal straight line with division points left to right A, B, C, D (AB the given line, BC/BD the annexes, wholes AC/AD). Below is a rectangle divided by two interior vertical lines into three panels, representing the squares and rectangles EG, KG, EL, KL laid along the rational line EF. Its top edge carries the points E, K, H, M (left to right) and its bottom edge the points F, I, G, L; the left side is EF, the interior verticals are KI and HG, and the right side is ML.

- A, B, C, D (upper line): the line divided as in the proof (AB minor part; wholes AC, AD)
- E (top-left corner): head of the rational line EF
- K, H (top interior): feet of the interior verticals KI, HG
- M (top-right corner): head of the right side ML
- F (bottom-left corner): foot of EF
- I, G (bottom interior): feet of the interior verticals
- L (bottom-right corner): foot of ML

DEFINITIONS, GROUP THREE

Given an assigned rational line and an apotome: if the whole is greater in square than the annex by the square on a straight line commensurable in length with itself —

I. If the whole is commensurable in length with the assigned rational, let it be called a *first apotome*.

II. If, however, the annex is commensurable in length with the assigned rational, let it be called a *second apotome*.

III. But if neither the whole nor the annex is commensurable in length with the assigned rational, let it be called a *third apotome*.

Again, if the whole is greater in square than the annex by the square on a straight line incommensurable in length with itself —

IV. If the whole is commensurable in length with the assigned rational, let it be called a *fourth apotome*.

V. If, however, the annex is commensurable in length with the assigned rational, let it be called a *fifth apotome*.

VI. But if neither the whole nor the annex is commensurable in length with the assigned rational, let it be called a *sixth apotome*.

SCHOLIUM.

The number of these six apotomes is reached in exactly the same way that the number of the six binomial lines was arrived at above. For these six apotomes are the straight lines that are left after the lesser terms are subtracted from the greater terms of the six lines that are called binomials [lines named from two terms], as is clear from the definitions.

PROBL. 19. PROPOS. 86.

[Margin: LXXXV. / LXXX.]

To find a first apotome.

Having found two square numbers AB, CB — as we taught in the second scholium to Prop. 29 of this book — whose difference AC is not a square, so that AB and CB have to one another the ratio a square number has to a square number, but AB and AC do not: let some rational line D be set out, with which EF is commensurable in length. Then EF, being commensurable with the rational D, will be rational. Next, let it be contrived that as the number AB is to the number AC, so — by the corollary

to Prop. 6 of this book — the square on EF is to the square on GF. I say that EG is a first apotome. For since the squares on EF, GF, having to one another the ratio the numbers AB, AC have, are commensurable [Margin: a — X.6], the straight lines EF, GF will also be commensurable, at least in square. Since, then, EF has been

shown to be rational, GF will be rational too. But since AB, AC do not have to one another the ratio a square number has to a square number, neither will the squares on EF, GF have the ratio of square numbers. Therefore the straight lines EF, GF are incommensurable in length [Margin: b — X.9]. Hence EF, GF are rational lines commensurable in square only, and so the remainder EG is an apotome [Margin: c — X.74]. I say it is also a first apotome. For let EF be greater in square than GF by the square on H. Since it is as the number AB is to the number AC, so the square on EF to the square on GF, it will be, by conversion of the ratio, as AB is to CB, so the square on EF to the square on H. But AB, CB have to one another the ratio of square numbers; therefore the squares on EF and H also have the ratio of square numbers, and consequently the straight lines EF and H are commensurable in length [Margin: d — X.9]. Since, then, the whole EF is greater in square than its annex GF by the square on H, which is commensurable in length with itself, and since the same whole EF is commensurable in length with the assigned rational D, EG will, by the first definition, be a first apotome. We have therefore found a first apotome. Which was to be done.

Diagram. The figure for Prop. 86 (repeated from the previous page). It has four rows: a dotted line marked A, C, B (C between A and B) representing the numbers AB, CB, AC; the rational line D; the line EF divided at G (EF the whole, GF the annex, EG the apotome-remainder); and below them the line H (by whose square EF exceeds GF).

- A, C, B (dotted line): the numbers AB, CB and their difference AC
- D: the assigned rational line
- E, G, F: the line EF divided at G into the apotome EG and the annex GF
- H: the line on which the excess of the square is taken

PROBL. 20. PROPOS. 87.

[Margin: LXXXVI. / LXXXI.]

To find a second apotome.

Having found two square numbers AB, CB, as in the preceding proposition, and a rational line D having been set out, let GF be taken commensurable in length with it; then GF will be commensurable with the rational D, and so rational too. Next, let it be contrived that as the number AC is to the number AB, so the square on GF is to the square on EF, by the corollary to Prop. 6 of this book. I say that EG is a second apotome. For since the squares on GF, EF, having to one another the ratio the numbers AC, AB have, are commensurable [Margin: a — X.6], the straight

lines GF, EF will also be commensurable, at least in square. Since, then, GF has been shown to be rational, EF will be rational too. But since the numbers AC, AB — and consequently the squares on GF, EF — do not have to one another the ratio of square numbers, GF, EF will be incommensurable in length [Margin: b — X.9]; hence GF, EF are rational lines commensurable in square only, and so the remainder EG is an apotome [Margin: c — X.74]. I say it is also a second apotome. For let EF be greater in square than GF by the square on H. Since, then, it is as AC is to AB, so the square on GF to the square on EF, and, by conversion, as AB is to AC, so the square on EF to the square on GF, we shall show — just as in the preceding proposition — that the line H is commensurable in length with EF. Therefore, since the whole EF is greater in square than its annex GF by the square on H, which is commensurable in length with itself, and since the annex GF is commensurable in length with the assigned rational D, EG will, by the second definition, be a second apotome. We have therefore found a second apotome. Which was to be done.

Diagram. The figure for Prop. 87, in four rows: a dotted line marked A, C, B (C between); the rational line D (with interior tick marks); the line EF divided at G (whole EF, annex GF, remainder EG); and the line H below.

- A, C, B (dotted line): the numbers AB, CB and their difference AC
- D: the assigned rational line
- E, G, F: the line EF divided at G into the apotome EG and the annex GF
- H: the line by whose square EF exceeds GF

PROBL. 21. PROPOS. 88.

[Margin: LXXXVII. / LXXXII.]

To find a third apotome.

Having found two square numbers AB, CB, as in Prop. 86, let another number I be taken — as we taught in Prop. 51 of this book — which has to neither of them, AB, AC, the ratio a square has to a square. Then, a rational line D having been set out, let it be contrived that as I is to AB, so the square on D is to the square on EF, by the corollary to Prop. 6 of this book. Then the squares on D and EF, having to one another the ratio the numbers I, AB have, will be commensurable [Margin: a — X.6]; and consequently the straight lines D and EF will be commensurable, at least in square. Since, then, D is rational, EF will be rational too. And since the numbers I, AB — and therefore the squares on D, EF — do not have to one another the ratio of square numbers, the straight lines D, EF will be

incommensurable in length [Margin: b — X.9]. Again, let it be contrived that as AB is to AC, so the square on EF is to the square on GF, from the same corollary to Prop. 6 of this book. I say that EG is a third apotome. For since the squares on EF [GF], having to one another the ratio the numbers AB, AC have, are commensurable [Margin: c — X.6], the straight lines EF, GF will also be commensurable, at least in square. Since, then, EF has been shown to be rational, GF will be rational too, being commensurable with it, as we demonstrated. And since AB, AC — and therefore the squares on EF, GF — do not have to one another the ratio of square numbers, the straight lines EF, GF will be incommensurable in length [Margin: d — X.9]. Therefore EF, GF are rational lines commensurable in square only; and consequently, since from EF there is subtracted GF, commensurable with it in square only, the remainder EG will be an apotome [Margin: e — X.74]. I say it is also a third apotome. For since it is as I is to AB, so the square on D to the square on EF, and as AB is to AC, so the square on EF to the square on GF, it will be, *ex aequali*, as I is to AC, so the square on D to the square on GF. But the numbers I and AC do not have to one another the ratio of square numbers; therefore neither will the squares on D and GF have the ratio of square numbers, and so the straight lines D and GF are incommensurable in length [Margin: f — X.9]. Therefore neither of the lines EF, GF is commensurable in length with the assigned rational D. Now let EF be greater in square than GF by the square on H; and we shall show, as in Prop. 86, that H is commensurable in length with EF. Therefore, since the whole EF is greater in square than its annex GF by the square on H, which is commensurable in length with itself, and since neither of the lines EF, GF is commensurable in length with the assigned rational D, EG will, by the definition, be a third apotome. We have therefore found a third apotome. Which was to be done.

Diagram. The figure for Prop. 88, in five rows: a dotted line marked A, C, B (C between); a second dotted line marked I (the auxiliary number); the rational line D (with interior tick marks); the line EF divided at G (whole EF, annex GF, remainder EG); and the line H below.

- A, C, B (dotted line): the numbers AB, CB and their difference AC
- I (dotted line): the auxiliary number taken by Prop. 51
- D: the assigned rational line
- E, G, F: the line EF divided at G into the apotome EG and the annex GF
- H: the line by whose square EF exceeds GF

PROBL. 22. PROPOS. 89.

[Margin: lxxxviii / lxxxiii]

To find the fourth apotome.

When two numbers AC, CB have been found such that AB, composed of them, has to neither of them the ratio that a square number has to a square number — by the method we taught in scholium 3 of proposition 29 of this book — let a rational line D be set out, and let EF be commensurable in length with it; EF too will therefore be rational. Now if the rest is carried out as we showed in proposition 86, EG will there be an apotome. I say it is also a fourth apotome. For let EF be such that it exceeds GF by the square on the straight line H. And since AB is to AC as the square on EF is to the square on GF, by conversion of the ratio AB will be to CB as the square on EF is to the square on H. Since, then, AB and CB do not have to one another the ratio of square numbers, [Margin: a — *Elements* X.9] the lines EF and H will be incommensurable in length. Since therefore the whole EF exceeds the annex GF by the square on H — a line incommensurable in length with it — while the same whole EF is commensurable in length with the rational D, by definition EG is a fourth apotome. We have therefore found a fourth apotome. Q.E.F.

Diagram. A group of four horizontal reference lines for the construction of the fourth apotome. From top to bottom:

- Top: a dotted number-line $A \cdots \cdots C \cdots B$ — the numbers AB (whole), CB, and their difference AC.
- Second: line **D**, ruled with tick-marks (the assigned rational line).
- Third: line **E — G — F** — the divided line EF, with G marking off the apotome EG and the annex GF.
- Bottom: line **H —** — the excess line (that by whose square EF exceeds GF).

PROBL. 23. PROPOS. 90.

[Margin: lxxxix / lxxxiv]

To find the fifth apotome.

When two numbers AC, CB have been found as in the preceding proposition, let the construction be made as in proposition 87 — that is, let GF be taken commensurable in length with the rational D, and so on. We shall then show, as

in proposition 87, that EG is an apotome. I say it is also a fifth apotome. For let EF be such that it exceeds GF by the square on the straight line H. And since similarly, as we show in proposition 86, by conversion of the ratio AB is to CB as the square on EF is to the square on H, the lines EF and H will again, as in the preceding proposition, be incommensurable in length; and the annex GF is commensurable in length with the rational D; therefore by definition EG is a fifth apotome. We have therefore found a fifth apotome. Q.E.F.

Diagram. The same set of four reference lines for the fifth apotome:

- Top: dotted number-line $A \cdots \cdots C \cdots \cdots B$ — numbers AB, CB, difference AC.
- Second: line **D**, ruled with tick-marks (assigned rational line).
- Third: line **E** — **G** — **F** — divided line EF, G marking apotome EG and annex GF (here GF is the greater part, commensurable with the rational).
- Bottom: line **H** — (with a light under-stroke) — the excess line.

PROBL. 24. PROPOS. 91.

[Margin: lxxxx / lxxxv]

To find the sixth apotome.

When three numbers AC, CB, and I have been found as in proposition 54, so that AB has to neither of them, AC nor CB — and I has to neither of AB, AC — the ratio that a square number has to a square number, let the rational D be set out and the rest be done as in proposition 88. We shall then show similarly, as there, that D and EF are incommensurable in length. I say it is also a sixth apotome. For, as in proposition 88, D and GF will likewise be incommensurable in length; and so neither of the lines EF, GF is commensurable in length with the assigned rational D. Now let EF exceed GF by the square on the straight line H, which we shall show, as in proposition 89, to be incommensurable in length with EF itself. Since therefore the whole EF exceeds the annex GF by the square on H — a line incommensurable in length with it — and neither of the lines EF, GF is commensurable in length with the rational D, by definition EG is a sixth apotome. We have therefore found a sixth apotome. Q.E.F.

Diagram. Five reference lines for the sixth apotome:

- Top: dotted number-line $A \cdots \cdots C \cdots \cdots B$ — numbers AB, CB, difference AC.

- Second: dotted line **I** ······· — the auxiliary number I (of proposition 54), labelled I at the left, unmarked at the right.
- Third: line **D**, ruled with tick-marks (assigned rational line).
- Fourth: line **E** — **G** ————— **F** — divided line EF, G marking apotome EG and annex GF.
- Bottom: line **H** ————— — the excess line.

SCHOLIUM.

But we shall also find the said six apotomes more expeditiously by the following method, as Theon teaches in this place.

Let it be required, for example, to find a first apotome. First let a first binomial AB be found, whose greater term is AC and lesser CB. Then from AC let there be cut off a straight line CD equal to CB itself. I say that AD is a first apotome. For since AC, BC are rationals commensurable in square only, AC, DC will also be rationals commensurable in square only. [Margin: a — *Elements* X.49] Therefore AD is an apotome. [Margin: b — *Elements* X.74] And since AC exceeds CB — that is, exceeds DC — by the square on a straight line commensurable in length with itself, and is commensurable in length with the assigned rational (by the definition of that which is called a first binomial), AD will, by the definition of a first apotome, be a first apotome. In the same way, from the others that are called binomials we shall find the other apotomes as well — the second from the second, the third from the third, the fourth from the fourth, the fifth from the fifth, and the sixth from the sixth — if we subtract the lesser terms from the greater.

Diagram. A single straight segment for the scholium's construction of the first apotome, with points from left to right:

- A (left endpoint): start of the binomial line.
- D (near left, with a tick): the point marking the apotome AD.
- C (middle): the division of the binomial (greater term AC, lesser CB), with CD = CB cut off.
- B (right endpoint).

THEOR. 68. PROPOS. 92.

[Margin: lxxxxi / lxxxvi]

If a rectangle is contained by a rational line and a first apotome, the straight line whose square equals the rectangle is an apotome.

Let the rectangle AC be contained by the rational AB and the first apotome AD. I say that the straight line whose square equals the rectangle AC is an apotome. Let DE be the annex to AD. Then by the definition of a first apotome, AE, DE will be rationals commensurable in square only; the whole AE will be commensurable in length with the rational AB; and finally the same whole AE will exceed its annex DE by the square on a straight line commensurable in length with itself. Let DE be bisected at F, and to AE let there be applied a rectangle equal to the square on FE — that is, to the fourth part of the square on DE — namely the rectangle contained by AG, GE, deficient by a square figure, by lemma 2 of proposition 17 of this book. And since AE exceeds DE by the square on a straight line commensurable in length with itself, [Margin: a — *Elements* X.18] the lines AG, GE will be commensurable in length; [Margin: b — *Elements* X.16] and therefore each of them will be commensurable in length with the whole AE. But AE is commensurable in length with the rational AB. [Margin: c — *Elements* X.12] Therefore each of AG, GE is also commensurable in length with AB; and by definition 6 they are rational. Hence, drawing GH, EI parallel to AB, meeting BC produced at H, I, [Margin: d — *Elements* X.20] each rectangle AH, GI, being contained by two rationals commensurable in length, will be rational.

Again, since each of DF, FE is commensurable in length with DE, while DE is incommensurable in length with the rational AB — for if it were commensurable in length, then since AE too is commensurable in length with AB, [Margin: e — *Elements* X.12] AE and DE would be commensurable in length as well, which is absurd, since they are assumed commensurable in square only — [Margin: f — *Elements* X.14] each of DF, FE will also be incommensurable in length with AB. And since each of DF, FE is commensurable with the rational DE and so is rational, both AB, DF and AB, FE will be rationals commensurable in square only. Hence, drawing FK parallel to AB, [Margin: g — *Elements* X.22] each rectangle DK, FI, contained by rationals commensurable in square only, will be medial.

Now on AH let there be constructed an equal square LM, [Margin: h — *Elements* II.14] and on GI an equal square NO, having with LM the common angle LPM. [Margin: i — *Elements* VI.26] Then the squares LM, NO will be about the same diameter, which let be PQ. And let the figure be completed as you see. Since, then, the rectangle contained by AG, GE is by construction equal to the square on FE, [Margin: k — *Elements* VI.17] the three lines AG, FE, GE will be proportional; [Margin: l — *Elements* VI.1] and therefore, since AH, FI, GI have the same ratio as these, FI will be a mean proportional between AH, GI — that is, between the squares LM, NO equal to them. But between these same LM, NO the mean proportional is also LO, by the lemma of proposition 14 of this book. Therefore

the rectangles FI, LO are equal. [Margin: m — *Elements* X.36] But DK is equal to FI, and MN is equal to LO. Therefore the whole DI is equal to the whole gnomon VYX together with the square NO. But the whole AI is by construction equal to the squares LM, NO. Therefore the remainder AC is also equal to the remaining square TR; and consequently the straight line TS is that whose square equals the rectangle AC. I say that TS is an apotome.

For since the spaces AH, GI have been shown to be rational, and LM, NO are equal to them, the squares LM, NO will also be rational, and therefore the lines TO, SO rational. Again, since FI has been shown to be medial, LO, equal to it, will also be medial. Therefore LO and NO are incommensurable, since the one is irrational and the other rational. Therefore the lines TO, SO, [Margin: n — *Elements* VI.1] having the same ratio as LO, NO, [Margin: o — *Elements* X.10] are incommensurable in length; [Margin: p — *Elements* X.74] and consequently the remainder TS is an apotome. If therefore a rectangle is contained by a rational and a first apotome, and so on. Q.E.D.

Diagram. Two figures for proposition 92. The upper figure is a rectangle with its long side AE (the rational base runs along the bottom BI), divided by verticals; the lower figure is a square with an inscribed diagonal and gnomon.

Upper (rectangle):

- Top edge, left to right: A, D, F, G, E.
- Bottom edge, left to right: B, C, K, H, I.
- Verticals dropped: DC, FK, GH, EI (defining rectangles AH, GI, DK, FI).

Lower (square):

- L (top-left), N (top-mid), P (top-right).
- T (mid-left), V and S (interior, S at the centre where the diagonal crosses), O (mid-right).
- Q (bottom-left), R (bottom-mid), M (bottom-right).
- Diagonal QP through S; y (interior, upper-right, on the diagonal) and X (interior, lower-mid); a circular arc drawn about S. The gnomon named in the text is VYX. Squares: LM (whole, L to M), NO (N to O); diameter PQ.

THEOR. 69. PROPOS. 93.

[Margin: lxxxxii / lxxxvii]

If a rectangle is contained by a rational line and a second apotome, the straight line whose square equals the rectangle is a first apotome of a medial.

Let the rectangle AC be contained by the rational AB and the second apotome AD. I say that the straight line whose square equals the rectangle AC is a first apotome of a medial. Let DE be the annex to AD. Then by the definition of a second apotome, AE, DE will be rationals commensurable in square only; the annex DE will be commensurable in length with the rational AB; and finally AE will exceed DE by the square on a straight line commensurable with itself in length. Let DE be bisected at F, and let everything else be constructed as in the preceding proposition. [Margin: a] Then again, as in the preceding proposition, AG, GE will be commensurable in length; [Margin: b] and therefore each of them will be commensurable in length with the whole AE. But AE is incommensurable in length with the rational AB — for if it were commensurable with AB in length, since DE is assumed commensurable in length with the same AB, [Margin: c] AE and DE would be commensurable with one another in length as well, which is absurd, since they are assumed commensurable in square only. [Margin: d] Therefore each of AG, GE is incommensurable in length with the same AB.

But each of AG, GE is commensurable with the rational AE and so is rational. Therefore both AB, AG and AB, GE are rationals commensurable in square only; [Margin: e — *Elements* X.22] and therefore each rectangle AH, GI, being contained by rationals commensurable in square only, is medial. Again, since each of DF, FE is commensurable in length with DE, and DE is assumed commensurable in length with the rational AB, each of DF, FE will also — as we showed in the scholium to proposition 12 of this book — be commensurable in length with the same rational AB, and hence rational. [Margin: f — *Elements* X.20] Therefore each rectangle DK, FI, being contained by rationals commensurable in length, is rational. Now, as in the preceding proposition, we shall demonstrate that the line TS is that whose square equals the rectangle AC. I say that TS is a first apotome of a medial.

For since AG, GE are commensurable in length, [Margin: g — *Elements* X.20] AH, GI, having the same ratio as they, will be commensurable; and therefore the squares LM, NO equal to them will be commensurable. Hence their sides too, namely the lines TO, SO, will be at least commensurable in square. And they are also medial, since the squares LM, NO are equal to the medials AH, GI (for AH, GI have been shown to be medial), so that they too are medial. And since FI — and therefore LO, equal to it — is rational, and consequently incommensurable with

the medial NO, the lines TO, SO, having the same ratio as these, will be incommensurable in length. Since therefore they have been shown to be both medial and commensurable in square, TO, SO will be medials commensurable in square only. And since they contain LO, which has been shown to be rational, [Margin: h — *Elements* X.75] TS will be a first apotome of a medial. If therefore a rectangle is contained by a rational and a second apotome, and so on. Q.E.D.

Diagram. Two figures for proposition 93, drawn (and reprinted from the foot of the preceding page) in the outer column. The upper is a tall rectangle divided by horizontals; the lower is the square with diagonal and gnomon.

Upper (rectangle):

- Left edge, top to bottom: A, D, F, G, E.
- Right edge, top to bottom: B, C, K, H, I.
- Horizontals: AB (top), DC, FK, GH, EI (bottom), marking off the rectangles AH, DK, GI, FI.

Lower (square):

- L (top-left), N (top-mid), P (top-right).
- T (mid-left), V and S (interior, S at centre), O (mid-right).
- Q (bottom-left), R (bottom-mid), M (bottom-right).
- Diagonal QP through S; y (interior upper-right, on the diagonal), X (interior lower-mid); circular arc about S; gnomon VYX; squares LM and NO; diameter PQ.

THEOR. 70. PROPOS. 94.

[Margin: lxxxxiii / lxxxviii]

If a rectangle is contained by a rational line and a third apotome, the straight line whose square equals the rectangle is a second apotome of a medial.

Let the rectangle AC be contained by the rational AB and the third apotome AD. I say that the straight line whose square equals the rectangle AC is a second apotome of a medial. For let DE be the annex to AD. Then by the definition of a third apotome, AE, DE will be rationals commensurable in square only, and neither of them, AE nor DE, is commensurable in length with the rational AB; and finally AE will exceed DE by the square on a straight line commensurable in length with itself. Let DE be bisected at F, and let the rest be done as in

proposition 92. Then again, as there, AG, GE will be commensurable in length with one another; [Margin: a — *Elements* X.16] and therefore each of them will also be commensurable in length with the whole AE. But AE is assumed incommensurable in length with the rational AB. [Margin: b — *Elements* X.14] Therefore each of AG, GE will also be incommensurable in length with the same AB. Since, then, each of AG, GE is commensurable with the rational AE and so is rational, both AB, AG and AE, GE will be rationals commensurable in square only; [Margin: c — *Elements* X.22] and therefore each rectangle AH, GI will be medial. Again, since DE is assumed incommensurable in length with the rational AB, each of DF, FE — being commensurable in length with DE — will [Margin: d — *Elements* X.14] be incommensurable in length with the same AB. Since, then, each of DF, FE is commensurable with the rational DE and so is rational, both AB, DF and AB, FE will be rationals commensurable in square only; [Margin: e — *Elements* X.22] and therefore each rectangle DK, FI will be medial. In the same way we shall now demonstrate, as in proposition 92, that the line TS is that whose square equals the rectangle AC. I say that TS is a second apotome of a medial.

For since AH, GI have been shown to be medial, the squares LM, NO equal to them will be medial; and therefore the lines TO, SO will be medial. And since AH, GI, having the same ratio as AG, GE (which we showed to be commensurable), [Margin: f — *Elements* X.10] are commensurable, the squares LM, NO too will be commensurable. Therefore the lines TO, SO are commensurable at least in square. But since AE, DE are commensurable in square only — that is, incommensurable in length — while GE is shown commensurable in length with AE and FE is commensurable in length with DE, GE and FE will, by the scholium to proposition 14 of this book, be incommensurable in length; [Margin: g — *Elements* X.10] and therefore GI, FI, having the same ratio as GE, FE — that is, NO, LO equal to them — are incommensurable. Hence TO, SO, having the same ratio as LO, NO, are incommensurable in length. But they have been shown to be medial and commensurable. Therefore TO, SO are medials commensurable in square only. And since they contain LO, a medial (for since LO is equal to FI, as is established from proposition 92, which we showed to be medial, LO too will be medial), [Margin: h — *Elements* X.76] TS will be a second apotome of a medial. If therefore a rectangle is contained by a rational and a third apotome, and so on. Q.E.D.

THEOR. 71. PROPOS. 95.

[Margin (beside heading): xciv. / lxxxix.]

If a space is contained by a Rational and a fourth apotome, the straight line whose square is equal to the space is a minor.

Demonstration. Let the space AC be contained by the Rational AB and the fourth apotome AD. I say that the straight line whose square equals the space AC is a minor. Let DE be the annex to AD. Then, by the definition of the fourth apotome, AE and DE are Rational and commensurable in square only; AE is commensurable in length with the Rational AB; and the square on AE exceeds the square on DE by the square on a straight line incommensurable in length with AE. Let DE be bisected at F, and let everything else be constructed as before. [Margin: a → Elem. X.19] Then AG, GE are incommensurable in length, since the square on AE exceeds the square on DE by the square on a straight line incommensurable with AE; and to AE there has been applied the rectangle contained by AG, GE, equal to a quarter of the square on DE and falling short by a square figure. And since AE is Rational and commensurable in length with the Rational AB, [Margin: b → Elem. X.20] the rectangle AI is Rational. Again, since DE is Rational but incommensurable in length with the Rational AB, [Margin: c → Elem. X.22] DI, and therefore also its half FI, is medial. Further, since AG, GE are incommensurable in length, [Margin: d → Elem. X.10] AH and GI, which have the same ratio to them, are incommensurable. Now we shall likewise prove, as in Proposition 92, that the straight line TS has its square equal to the space AC. I say that TS is a minor.

For by the construction, the rectangle AI is equal to the sum of the squares LM, NO on the straight lines TO, SO; and that sum was shown to be Rational; therefore the sum of the squares on TO, SO is Rational. Likewise, since F [i.e. FI] was shown to be medial, LO — contained by TO, SO and equal to it — is also medial. Finally, since AH, GI were proved incommensurable, the squares LM, NO equal to them are also incommensurable; and therefore the straight lines TO, SO are incommensurable in square. Therefore, since TO, SO are incommensurable in square, the sum of their squares being Rational but the rectangle contained by them being medial, [Margin: e → Elem. X.77] the remainder TS is a minor. Therefore, if a space is contained by a Rational and a fourth apotome, and so on. Which was to be demonstrated.

Diagram. The figure for this proposition has two parts, one above the other.

- Upper part — a rectangle divided into vertical strips. Top edge, left to right: A, D, F, G, E. Bottom edge, left to right: B, C, K, H, I. (AB is the left side, the Rational; AE the top side; the interior verticals through D/C, F/K, G/H mark the sub-rectangles AI, DI, and the rectangle contained by AG, GE.)

- Lower part — a square with an inscribed semicircle and a diagonal, used to construct the two lines TO, SO.
- L (top-left corner), N (top edge, middle), P (top-right corner)
- T (mid-height, left edge), V (just left of centre), S (centre), O (mid-height, right edge)
- Q (bottom-left corner), R (bottom edge, middle), M (bottom-right corner)
- a diagonal drawn from Q to P; a circle/semicircle centred near S; a small label **y** on the diagonal above S, and **x** just below S.

THEOR. 72. PROPOS. 96.

[Margin (beside heading): lxxxxv. / lxxxx.]

If a space is contained by a Rational and a fifth apotome, the straight line whose square is equal to the space is that which produces with a Rational area a medial whole.

Demonstration. Let the space AC be contained by the Rational AB and the fifth apotome AD (the figure of the immediately preceding proposition being repeated). I say that the straight line whose square equals the space AC is that which produces with a Rational area a medial whole. Let DE be the annex to AD. Then, by the definition of the fifth apotome, AE, DE are Rational and commensurable in square only; DE is commensurable in length with the Rational AB; and finally the square on AE exceeds the square on DE by the square on a straight line incommensurable in length with AE. Let DE be bisected at F, and let the rest be constructed as before. Then again, as in the preceding proposition, AG, GE are incommensurable in length. And since AE is Rational but incommensurable in length with the Rational AB, as we said in Proposition 93, [Margin: $a \rightarrow$ Elem. X.22] the rectangle AI is medial. Likewise, since DE is Rational and commensurable in length with the Rational AB, [Margin: $b \rightarrow$ Elem. X.20] DI, and therefore also its half FI, is Rational. Again, as in the preceding proposition, AH, GI are incommensurable; and, as was shown in Proposition 92, the straight line TS has its square equal to the space AC. I say that TS is that which produces with a Rational a medial whole.

For since AI was shown to be medial, the sum of the squares LM, NO on TO, SO, equal to it, is also medial. Likewise, since we proved FI to be Rational, LO — the rectangle contained by TO, SO, being equal to it — is also Rational. But TO, SO are incommensurable in square, as was demonstrated in the preceding proposition. Therefore, since TO, SO are incommensurable in square, the sum of their squares being medial but the rectangle contained by them being Rational, [Margin: $c \rightarrow$

Elem. X.78] the remainder TS is that which produces with a Rational a medial whole. And so, if a space is contained by a Rational and a fifth apotome, and so on. Which was to be demonstrated.

Diagram. The same composite figure as for the preceding proposition, printed again for this proposition. Upper part: a rectangle with top edge A, D, F, G, E and bottom edge B, C, K, H, I. Lower part: a square with top corners/edge L, N, P; mid-line T, V, S, O; bottom Q, R, M; with an inscribed circle, a diagonal from Q to P, and the labels y (above S) and x (below S).

THEOR. 73. PROPOS. 97.

[Margin (beside heading): lxxxxvi. / lxxxxj.]

If a space is contained by a Rational and a sixth apotome, the straight line whose square is equal to the space is that which produces with a medial area a medial whole.

Demonstration. Let the space AC be contained by the Rational AB and the sixth apotome AD. I say that the straight line whose square equals the space AC is that which produces with a medial area a medial whole. For let DE be the annex to AD. Then, by the definition of the sixth apotome, AE, DE are Rational and commensurable in square only; neither of them, AE, DE, is commensurable in length with the Rational AB; and finally the square on AE exceeds the square on DE by the square on a straight line incommensurable in length with AE. Let DE be bisected at F, and let the rest be constructed as above. Then again, as in Proposition 95, AG, GE are incommensurable in length. And since both AE and DE are Rational but incommensurable in length with the Rational AB, [Margin: a $\rightarrow$ Elem. X.22] both AI and DI, and therefore also the half of DI, namely FI, are medial. And, as in Proposition 95, AH, GI are incommensurable. And since AE, DE are commensurable in square only, [Margin: b $\rightarrow$ Elem. X.10] AI, DI, which have the same ratio to them, are incommensurable; and moreover, since DI, FI are commensurable, [Margin: c $\rightarrow$ Elem. X.14] FI is incommensurable with AI. Now we shall prove, as in Proposition 92, that the straight line TS has its square equal to the space AC. I say that TS is that which produces with a medial area a medial whole.

For since we showed AI to be medial, the sum of the squares LM, NO on TO, SO, equal to it, is also medial. Likewise, since FI was shown to be medial, LO equal to it — contained by TO, SO — is also medial. Again, since FI is incommensurable with AI, as we showed, LO contained by TO, SO is also incommensurable with the

sum of the squares on TO, SO — because LO is equal to FI, and the sum of the squares on TO, SO is equal to AI. Finally, TO, SO are incommensurable in square, as was demonstrated in Proposition 95. Therefore, since TO, SO are incommensurable in square, and the sum of their squares is medial, and likewise the rectangle contained by them is medial, and moreover incommensurable with the sum of their squares, [Margin: d → Elem. X.79] the remainder TS is that which produces with a medial area a medial whole. Therefore, if a space is contained by a Rational and a sixth apotome, and so on. Which was to be shown.

Diagram. The same composite figure as before, printed again for this proposition. Upper part: a rectangle with top edge A, D, F, G, E and bottom edge B, C, K, H, I. Lower part: a square with top L, N, P; mid-line T, V, S, O; bottom Q, R, M; with an inscribed circle, a diagonal from Q to P, and the labels y (above S) and x (below S).

THEOR. 74. PROPOS. 98.

[Margin (beside heading): xcvij. / xcij.]

The square on an apotome, applied to a Rational, produces as its breadth a first apotome.

Demonstration. Let AB be an apotome and BC its annex, so that AC, BC are Rational and commensurable in square only; [Margin: a → Elem. I.45] and to the Rational DE let the rectangle DF be applied, equal to the square on AB, producing as breadth DG. I say that DG is a first apotome. For to the same DE let the rectangle DH be applied, equal to the square on AC; and to HI another, IK, equal to the square on BC; so that the whole DK is equal to the sum of the squares on AC, BC. [Margin: b → Elem. II.7 [recte: printed abbreviation reads "7.sexti", but the cited identity — the sum of the squares equals twice the rectangle together with the square on the difference — is Elem. II.7]] And since the sum of the squares on AC, BC is equal to twice the rectangle contained by AC, BC together with the square on AB, then if the square on AB and the rectangle DF be taken away, there remains GK equal to twice the rectangle contained by AC, BC; and therefore, GL being bisected at M and MN drawn parallel to DE, MK is equal to the rectangle contained by AC, BC. And since AC, BC are Rational, their squares on AC, BC are also Rational, and therefore commensurable. [Margin: c → Elem. X.16] Since, then, the sum of the squares on AC, BC is commensurable with each of them, that sum — that is, DK equal to it — is also Rational. And since it is applied to the Rational DE, [Margin: d → Elem. X.21] DL is Rational and commensurable in length with DE. Again, since AC, BC are Rational and commensurable in square only, the

rectangle contained by them, and therefore also its double GK, is medial. And since it is applied to the Rational GF, [Margin: e → Elem. X.23] GL is Rational but incommensurable in length with GF, that is, with DE. And since DK is Rational and GK medial — that is, irrational — they are incommensurable; [Margin: f → Elem. X.10] therefore the straight lines DL, GL, which have the same ratio as DK, GK, are incommensurable in length. And since they have both been shown to be Rational, DL, GL are Rational and commensurable in square only; [Margin: g → Elem. X.74] and therefore the remainder DG is an apotome. I say that it is also a first apotome.

For, by the Lemma to Proposition 54 of this book, the rectangle contained by AC, BC — that is, MK — is a mean proportional between the squares on AC, BC, that is, between DH and IK; therefore DH, MK, IK are in continued proportion; and therefore the straight lines DI, ML, IL, which have the same ratio to them, are also in continued proportion. [Margin: h → Elem. VI.17] Therefore the rectangle contained by DI, IL is equal to the square on ML, that is, to a quarter of the square on GL. And since the squares on AC, BC — that is, DH, IK equal to them — are commensurable, [Margin: i → Elem. X.10] the straight lines DI, IL, which have the same ratio to them, are commensurable in length. And so, since the two straight lines DL, GL are unequal,

Diagram. Two parts.

- A straight line marked A (left), B (near the right), C (right end) — the apotome AB with its annex BC, giving the whole AC.
- A rectangle divided into vertical strips: top edge, left to right, D, G, M, I, L; bottom edge, left to right, E, F, N, H, K. (D/E is the left side on the Rational DE; the verticals through G/F, M/N, I/H divide it into the rectangles DF, DH, IK and the strip GK bisected at M by MN.)

[Note: a small paper repair overlies the region near the label I; the figure is otherwise legible.]

and to the greater, DL, there is applied a rectangle contained by DI, IL, equal to a quarter of the square on the lesser GL and falling short by a square figure; and since DI has been shown commensurable in length with IL, [Margin: k → Elem. X.18] DL is capable of exceeding GL by the square on a straight line commensurable in length with itself. Therefore, since DG has been shown to be an apotome, and the whole DL exceeds its annex GL by the square on a straight line commensurable in length with itself, and this same whole DL is commensurable in length with the Rational DE, by definition DG is a first

apotome. Therefore the square on an apotome, applied to a Rational, produces as its breadth a first apotome. Which was to be shown.

Diagram. The figure carried over from the preceding proposition. A straight line marked A (left), B, C (right end); and a rectangle with top edge D, G, M, I, L and bottom edge E, F, N, H, K, divided into vertical strips by the lines through G/F, M/N, I/H.

THEOR. 75. PROPOS. 99.

[Margin (beside heading): xcviij. / lxxxxiij.]

The square on a first apotome of a medial, applied to a Rational, produces as its breadth a second apotome.

Demonstration. Let AB be a first apotome of a medial and BC its annex, so that AC, BC are medial and commensurable in square only and contain a Rational area; [Margin: a → Elem. I.45] and to the Rational DE let a rectangle DF equal to the square on AB be applied, producing as breadth DG. I say that DG is a second apotome. For let the same construction be made as in the preceding proposition, so that again DH, IK are equal to the squares on AC, BC, and GK equal to twice the rectangle contained by AC, BC, and consequently MK equal to the rectangle contained once by AC, BC. Since, then, AC, BC are medial and commensurable in square, their squares — that is, DH, IK equal to them — are also medial and commensurable; [Margin: b → Elem. X.16] and therefore the whole DK is commensurable with each of them, and hence also medial, by the corollary to Proposition 24 of this book. Since, then, DK is applied to the Rational DE, [Margin: c → Elem. X.23] DL is Rational but incommensurable in length with DE. Again, since the rectangle contained by AC, BC is assumed Rational, its double GK is also Rational. And since it is applied to the Rational DE, [Margin: d → Elem. X.21] GL is Rational and commensurable in length with DE. But since DK is medial — that is, irrational — and GK Rational, they are incommensurable; [Margin: e → Elem. X.10] therefore the straight lines DL, GL, which have the same ratio to them, are incommensurable in length. Since, then, they have been shown to be Rational, DL, GL are Rational and commensurable in square only; [Margin: f → Elem. X.74] and therefore the remainder DG is an apotome. I say that it is also a second apotome. For likewise, as in the preceding proposition, we shall prove that the whole DL exceeds its annex GL by the square on a straight line commensurable in length with itself. And since the annex GL has been shown commensurable in length with the Rational DE, by definition DG is a second apotome. Therefore the

square on a first apotome of a medial, applied to a Rational, produces as its breadth a second apotome. Which was to be shown.

Diagram. As before. A straight line marked A (left), B, C (right end); and a rectangle with top edge D, G, M, I, L and bottom edge E, F, N, H, K, divided into vertical strips.

THEOR. 76. PROPOS. 100.

[Margin (beside heading): lxxxxix. / xciv.]

The square on a second apotome of a medial, applied to a Rational, produces as its breadth a third apotome.

Demonstration. Let AB be a second apotome of a medial and BC its annex, so that AC, BC are medial and commensurable in square only and contain a medial area; [Margin: a → Elem. I.45] and to the Rational DE let DF be applied, equal to the square on AB, producing as breadth DG. I say that DG is a third apotome. For let the same construction be made, whereby we shall now show, as in the preceding proposition, that DK is medial, [Margin: b → Elem. X.23] and therefore that the straight line DL is Rational but incommensurable in length with DE. And since the rectangle contained by AC, BC is medial, and hence its double GK also, [Margin: c → Elem. X.23] GL too is Rational but incommensurable in length with DE. But since AC, BC are incommensurable in length, and as AC is to BC so — by Lemma 3 to Proposition 19 of this book — is the square on AC to the rectangle contained by AC, BC, [Margin: d → Elem. X.10] the square on AC is incommensurable with the rectangle contained by AC, BC. [Margin: e → Elem. X.16] But the sum of the squares on AC, BC is commensurable with the square on AC — since the squares described on the lines AC, BC, being commensurable in square, are commensurable — while the rectangle contained twice by AC, BC is commensurable with the rectangle contained by AC, BC. Therefore, by the scholium to Proposition 14 of this book, the sum of the squares on AC, BC — that is, DK — is incommensurable with twice the rectangle contained by AC, BC, [Margin: f → Elem. X.10] that is, with GK. And therefore the straight lines DL, GL, which have the same ratio as DK, GK, are incommensurable in length. But they have also been shown to be Rational. Therefore DL, GL are Rational and commensurable in square only; [Margin: g → Elem. X.74] and consequently the remainder DG is an apotome. I say that it is also a third. For likewise, as in Proposition 98, we shall prove that the whole DL exceeds its annex GL by the square on a straight line commensurable in length with itself. Since, then, neither of DL, GL is commensurable in length with the Rational DE, as was demonstrated,

by definition DG is a third apotome. Therefore the square on a second apotome of a medial, applied to a Rational, and so on. Which was to be shown.

Diagram. As before. A straight line marked A (left), B, C (right end); and a rectangle with top edge D, G, M, I, L and bottom edge E, F, N, H, K, divided into vertical strips.

Euclid, Book X (continued) — the Apotome (subtractive irrationals), closing propositions

(Clavius's commentary on Euclid's Elements. Enunciations are set as blockquotes; the demonstrations and scholia are Clavius's. Marginal citations are keyed to the lettered points of each proof — "dec." = Elements Book X, "sexti" = Book VI, "quint." = Book V, "prim." = Book I. The stacked lowercase-roman marginal counters beside each heading are the source's parallel proposition-numbering, transcribed verbatim.)

THEOR. 77. PROPOS. 101.

[Margin: c. / LXXXXV.]

The square on a minor line, applied to a rational line, produces as its breadth a fourth apotome.

Let AB be a minor line, and BC its annex, so that AC and BC are incommensurable in square, and make the sum of their squares rational but the rectangle contained by AC and BC medial [Margin: I.45]; and to the rational line DE let there be applied the area DF, equal to the square on AB, producing DG as breadth. I say that DG is a fourth apotome. For let everything be constructed as in what precedes.

Since, then, the sum of the squares on AC and BC — that is, the equal area DK — is rational, DL will be commensurable in length with the rational line DE [Margin: X.21]. Again, since the rectangle contained by AC, BC — and therefore also its double GL — is medial, GL will be incommensurable in length with the rational line DE [Margin: X.23]. Further, since DK is rational while GK is irrational, namely medial, and these are incommensurable, DL and GL, having the same ratio to them, will be incommensurable in length [Margin: X.10]. But they were shown to be rational. Therefore DL and GL are rational and commensurable in square only; and consequently the remainder DG is an apotome [Margin: X.74].

I say that it is also a fourth apotome. For since AC and BC are incommensurable in square, their squares too — that is, the equal areas DH and IK — will be incommensurable; and consequently the lines DI and IL are incommensurable in length [Margin: X.10]. Since, then, the rectangle contained by DI, IL is equal to the square on ML — that is, to the fourth part of the square on GL, as was demonstrated in proposition 98 — DL will be capable of more than GL by the square on a line incommensurable in length with itself [Margin: X.19]; for to DL, the greater, there has been applied a rectangle contained by DI, IL, equal to the fourth part of the square on GL and deficient by a square figure, and dividing the greater line DL into the parts DI, IL, incommensurable in length. And so, since the whole DL is capable of more than its annex GL by the square on a line incommensurable in length with itself, while the same whole DL was shown to be commensurable in length with the rational line DE, DG will by definition be a fourth apotome. Therefore the square on a minor line, applied to a rational line, and so on. Which was to be demonstrated.

Diagram. A straight line AB C at the top (A at the left, B and C together near the right), and beneath it a rectangle divided into vertical strips by internal lines.

- A (top line, left end): endpoint of the whole line
- B (top line, near right): division point (minor / annex)
- C (top line, right end): endpoint of the whole AC
- D (rectangle, top-left corner): breadth-line DL begins here
- G, M, I, L (rectangle, along the top edge): successive division points; L at the top-right corner
- E (rectangle, bottom-left corner)
- F, N, H, K (rectangle, along the bottom edge): division points beneath G, M, I, L respectively; K at the bottom-right corner

THEOR. 78. PROPOS. 102.

[Margin: ci. / LXXXXVI.]

The square on the line which, together with a rational area, makes the whole medial, applied to a rational line, produces as its breadth a fifth apotome.

Let AB be the line which together with a rational area makes the whole medial, and BC its annex, so that AC and BC are incommensurable in square, and make the sum of their squares medial but the rectangle contained by these same AC, BC rational [Margin: I.45]; and to the rational line DE let DF be applied, equal to the

square on AB, producing DG as breadth. I say that DG is a fifth apotome. For let the same things be constructed as above.

Since, then, the sum of the squares on AC and BC — and therefore also the equal area DK — is medial, DL will be incommensurable in length with the rational line DE [Margin: X.23]. Again, since the rectangle contained by AC, BC, and therefore also its double GK, is rational, GL will be commensurable in length with the rational line DE [Margin: X.21 (printed "deo," *recte* dec.)]. And since DK, being medial or irrational, and GK, being rational, are incommensurable, DL and GL, having the same ratio to them, will be incommensurable in length [Margin: X.10]. But they are also rational and commensurable in square only; and therefore the remainder DG is an apotome [Margin: X.74].

I say that it is also a fifth apotome. For in the same way as in the preceding proposition we shall demonstrate that the whole DL is capable of more than its annex GL by the square on a line incommensurable in length with itself. Since, then, the annex GL has been shown to be commensurable in length with the rational line DE, DG will by definition be a fifth apotome. Therefore the square on the line which together with a rational area makes the whole medial, and so on. Which was to be demonstrated.

Diagram. As in the previous figure: a straight line AB C at the top, and beneath it a rectangle divided into vertical strips.

- A (top line, left end); B (division point); C (top line, right end)
- D (top-left corner); G, M, I, L (along the top edge, L at top-right corner)
- E (bottom-left corner); F, N, H, K (along the bottom edge, K at bottom-right corner)

THEOR. 79. PROPOS. 103.

[Margin: cij. / lxxxxvij.]

The square on the line which, together with a medial area, makes the whole medial, applied to a rational line, produces as its breadth a sixth apotome.

Let AB be the line which together with a medial area makes the whole medial, and BC its annex, so that AC and BC are incommensurable in square, and make both the sum of their squares medial and the rectangle contained by these same AC, BC medial, and incommensurable with the sum of their squares [Margin: I.45]; and to the rational line DE let the area DF, equal to the square on AB, be

applied, producing DG as breadth. I say that DG is a sixth apotome. For let the same things be done as above.

Since, then, both the sum of the squares on AC, CB — that is, the equal area DK — and the rectangle contained by AC, BC (and therefore also its double GK) are medial, both DL and GL will be incommensurable in length with the rational line DE [Margin: X.23]. And since the rectangle contained by AC, BC is incommensurable with the sum of the squares on AC, BC, while the rectangle contained by AC, BC and its double GK are commensurable, GK too will be incommensurable with the same sum, that is, with DK [Margin: X.24]; and consequently DL and GL, having the same ratio as DK and GK, are incommensurable in length [Margin: X.10]. But they were also shown to be rational. Therefore DL and GL are rational and commensurable in square only; and therefore the remainder DG is an apotome [Margin: X.74].

I say that it is also a sixth apotome. For we shall show, in the same way as in proposition 101, that the whole DL is capable of more than its annex GL by the square on a line incommensurable in length with itself. Since, then, neither of the lines DL, GL is commensurable in length with the rational line DE, DG will by definition be a sixth apotome. Therefore the square on the line which together with a medial area makes the whole medial, and so on. Which was to be shown.

Diagram. As before: a straight line AB C above, and beneath it a rectangle divided into vertical strips.

- A (top line, left end); B (division point); C (top line, right end)
- D (top-left corner); G, M, I, L (along the top edge, L at top-right corner)
- E (bottom-left corner); F, N, H, K (along the bottom edge, K at bottom-right corner)

THEOR. 80. PROPOS. 104.

[Margin: ciiij. / xcviij.]

A straight line commensurable in length with an apotome is itself also an apotome, and of the same order.

Let AB be an apotome, and BC its annex, so that AC and BC are rational and commensurable in square only; and let DE be commensurable in length with AB. I say that DE too is an apotome, and of the same order as AB. For let it be contrived that as AB is to DE, so is BC to EF [Margin: VI.12]. Then the whole AC will be to the whole DF as AB is to DE, or as BC is to EF [Margin: V.12]. Since, then,

AB and DE are assumed commensurable in length, AC and DF, and likewise BC and EF, will also be commensurable in length [Margin: X.10]. And since AC, BC are rational, DF, EF, being commensurable with them, will also be rational.

Again, since as AC is to DF, so is BC to EF, then, alternately, as AC is to BC, so is DF to EF; and since AC, BC are commensurable in square only, DF, EF too will — by what we demonstrated at proposition 10 of this book — be commensurable in square only. Therefore, since they have also been shown to be rational, the remainder DE is an apotome [Margin: X.74].

I say that it is also of the same order as AB. First, let AC be capable of more than BC by the square on a line commensurable in length with itself. This granted, DF too will be capable of more than EF by the square on a line commensurable in length with itself [Margin: X.15]. So if AC is commensurable in length with the assigned rational line, so that AB is a first apotome, then DF too will be commensurable in length with the assigned rational line [Margin: X.12], since both the assigned rational line and DF are commensurable in length with the same AC. Therefore by definition DE too will be a first apotome, that is, of the same order as AB. But if BC is commensurable in length with the rational line, then in the same way EF will be commensurable in length with the rational line, and so both AB and DE will by definition be a second apotome. And if, finally, neither AC nor BC is commensurable in length with the assigned rational line, then neither of the lines DF, EF will be commensurable in length with the same rational line [Margin: X.14]; and so both AB and DE will by definition be a third apotome.

Now let AC be capable of more than BC by the square on a line incommensurable in length with itself. This granted, DF too will be capable of more than EF by the square on a line incommensurable in length with itself [Margin: X.15]. And so, as before, we shall show that DE is a fourth, fifth, or sixth apotome, and so on. Therefore a straight line commensurable in length with an apotome, and so on. Which was to be shown.

Diagram. Two horizontal straight lines. The upper line is marked A, B, C (A at the left, B a short mark near the middle-right, C at the right end); the lower line is marked D, E, F (D at the left, E near the middle-right, F at the right end). AB and BC are the apotome and its annex; DE and EF the corresponding parts of the derived line.

- A (upper line, left end); B (division point); C (upper line, right end)
- D (lower line, left end); E (division point); F (lower line, right end)

SCHOLIUM.

Here we shall say of apotomes the same thing that we wrote of the binomial lines at proposition 67 of this book — namely, that if the line DE is commensurable with AB in square only, it can be demonstrated in the same way (if in place of the phrase "commensurable in length" we use the phrase "commensurable in square only") that DE too is an apotome; but that it cannot be inferred that it is of the same order as AB. For it does not follow, if the whole AC is commensurable in length with the assigned rational line, that DF too is commensurable in length with it, because it is not the case that both — namely the assigned rational line and DF — are commensurable in length with the same AC; rather, the rational line is commensurable with it in length, whereas DF is so only in square, by hypothesis. Indeed, if AB is a first, second, fourth, or fifth apotome, it is in no way possible that DE, commensurable with it in square only, should be an apotome of the same order.

For let AB be a first apotome (or a second, fourth, or fifth), and BC its annex; and let DE be commensurable with AB in square only — which, as in the theorem, we shall show to be an apotome — and EF its annex, and let the parts AB, BC have the same ratio to the parts DE, EF as the wholes AC, DF have to one another. I say that on no account is DE an apotome of the same order as AB. For, if it were possible, let each be a first apotome. This granted, both the whole AC and the whole DF will, by the definition of a first apotome, be commensurable in length with the assigned rational line [Margin: X.12], and so AC and DF will also be commensurable in length with one another. Since, then, as AC is to DF, so is AB to DE, AB and DE too will be commensurable in length [Margin: X.10]. But this is absurd; for DE is assumed commensurable with AB in square only. Therefore AB and DE will not both be a first apotome. Nor yet a second or a fifth; for each of them, being commensurable with its annex BC, EF, would by definition be commensurable in length with the assigned rational line, and so also with one another. Consequently AB and DE would be commensurable in length with one another — which is not assumed.

It is nevertheless always true that, if AB is a first, second, or third apotome, the line DE which is commensurable with AB in square only is also one of those three, though not of the same order. For, this being granted, AC will be capable of more than BC by the square on a line commensurable in length with itself. Since, then, as AC is to BC, so is DF to EF, DF too will be capable of more than EF by the square on a line commensurable in length with itself [Margin: X.15]; and so by definition DE will be a first, second, or third apotome. In the same way, if AB is a

fourth, fifth, or sixth apotome — so that AC is capable of more than BC by the square on a line incommensurable in length with itself — DE too will be a fourth, fifth, or sixth apotome, though not of the same order as AB; because again, since as AC is to BC, so is DF to EF, DF too will be capable of more than EF by the square on a line incommensurable in length with itself [Margin: X.15]. And so by definition AB will be a fourth, fifth, or sixth apotome.

In the following four propositions, however, DE will necessarily be of the same order as AB, even though it is commensurable with it in square only.

THEOR. 81. PROPOS. 105.

[Margin: civ. / lxxxxix.]

A straight line commensurable with an apotome of a medial is itself also an apotome of a medial, and of the same order.

Let AB be any apotome of a medial, and BC its annex, so that AC and BC are medials commensurable in square only; and let DE be commensurable with AB, whether in both length and square or in square only. I say that DE too is an apotome of a medial, and of the same order as AB. For let it be contrived that as AB is to DE, so is BC to FE [recte: EF] [Margin: VI.12]. Then the whole AC will be to the whole DF as AB is to DE, and as BC is to EF [Margin: V.12]. Since, then, AB and DE are assumed commensurable, whether in both length and square or in square only, BC and EF, and AC and DF, will also be commensurable in the same way [Margin: X.10]. And since AC, BC are medials, DF, EF, being commensurable with them, will also be medials [Margin: X.24].

Again, since as AC is to DF, so is BC to EF, then, alternately, as AC is to BC, so is DF to EF; but AC, BC are commensurable in square only, so DF, EF too will — by the scholium to proposition 10 of this book — be commensurable in square only. Therefore, since DF, EF have been shown to be medials, the remainder DE is an apotome of a medial [Margin: X.75 or X.76].

I say that it is also of the same order as AB. For since as AC is to BC, so is DF to EF; and as AC is to BC, so is the square on AC to the rectangle contained by AC, BC (by lemma 3 of proposition 19 of this book), and as DF is to EF, so is the square on DF to the rectangle contained by DF, EF; then also, as the square on AC is to the rectangle contained by AC, BC, so is the square on DF to the rectangle contained by DF, EF. And, alternately, as the square on AC is to the square on DF, so is the rectangle contained by AC, BC to the rectangle contained by DF, EF. Since, then, the square on AC is commensurable with the square on DF — because the lines

AC, DF were shown to be commensurable — the rectangle contained by AC, BC will also be commensurable with the rectangle contained by DF, EF [Margin: X.10]. Therefore, if the rectangle contained by AC, BC is rational, so that AB is a first apotome of a medial, the rectangle contained by DF, EF will also be rational, since it is commensurable with it; and so DE too will be a first apotome of a medial [Margin: X.75]. But if the rectangle contained by AC, BC is medial, so that AB is a second apotome of a medial, the rectangle contained by DF, EF, being commensurable with it, will also be medial, by the corollary to proposition 24 of this book [Margin: X.76]; and consequently DE too will be a second apotome of a medial. Therefore a straight line commensurable with an apotome of a medial, and so on. Which was to be shown.

Diagram. Two horizontal straight lines. The upper line is marked A, B, C (A at the left, B near the middle, C at the right end); the lower line is marked D, E, F (D at the left, E near the middle, F at the right end).

- A (upper line, left end); B (division point); C (upper line, right end)
- D (lower line, left end); E (division point); F (lower line, right end)

THEOR. 82. PROPOS. 106.

[Margin: cv. cxvi. / c.]

A straight line commensurable with a minor line is itself also a minor line.

Let AB be a minor line, and BC its annex, so that AC and BC are incommensurable in square, and make the sum of the squares on AC, BC rational but the rectangle contained by these same AC, BC medial; and let DE be commensurable with AB, whether in both length and square or in square only. I say that DE too is a minor line. For let the same things be done as above, so that again AB, BC have the same ratio to DE, EF as AC has to DF. Then again, as in the preceding proposition, DF, EF will be commensurable with AC, BC, whether in both length and square or in square only.

And since as AC is to DF, so is BC to EF, then, alternately, as AC is to BC, so is DF to EF; hence as the square on AC is to the square on BC, so is the square on DF to the square on EF [Margin: VI.22]; and, componendo, as the sum of the squares on AC, BC is to the square on BC, so is the sum of the squares on DF, EF to the square on EF; and, alternately, as the sum of the squares on AC, BC is to the sum of the squares on DF, EF, so is the square on BC to the square on EF. But the square on BC is commensurable with the square on EF, because we showed the lines BC, EF

to be commensurable. Therefore the sum of the squares on AC, BC is also commensurable with the sum of the squares on DF, EF [Margin: X.10]. But the sum of the squares on AC, BC is, by the ninth definition and by hypothesis, rational. Therefore the sum of the squares on DF, EF is rational.

Again, since — as we shall demonstrate as in the preceding proposition — the rectangle contained by AC, BC is commensurable with the rectangle contained by DF, EF, and the rectangle contained by AC, BC is assumed medial, the rectangle contained by DF, EF will also be medial, by the corollary to proposition 24 of this book. And since as AC is to BC, so is DF to EF, and AC, BC are incommensurable in square, DF, EF too will be incommensurable in square [Margin: X.10]. And so, since DF, EF are incommensurable in square and make the sum of the squares on DF, EF rational but the rectangle contained by these same DF, EF medial, DE will be a minor line [Margin: X.77]. Therefore a straight line commensurable with a minor line, and so on. Which was to be demonstrated.

Diagram. Two horizontal straight lines. The upper line is marked A, B, C (A at the left, B near the middle with a division mark, C at the right end); the lower line is marked D, E, F (D at the left, E near the middle with a division mark, F at the right end).

- A (upper line, left end); B (division point); C (upper line, right end)
- D (lower line, left end); E (division point); F (lower line, right end)

PROBL. 83. PROPOS. 107.

[Margin: cvi. cxvii. / ci.]

A straight line commensurable with the line which together with a rational area makes the whole medial is itself also a line which together with a rational area makes the whole medial.

Let AB be the line which together with a rational area makes the whole medial, and BC its annex, so that AC and BC are incommensurable in square, and make the sum of the squares on AC, BC medial but the rectangle contained by AC, BC rational; and let DE be, in any manner whatever, incommensurable with AB. I say that DE too is a line which together with a rational area makes the whole medial. For, the same things being constructed as above, we shall show, as in the preceding proposition, that the sum of the squares on AC, BC is commensurable with the sum of the squares on DF, EF. Since, then, [the sum of the squares on AC, BC is] medial [by the] corollary to proposition 24 of this book, [the sum of the squares on DF, EF is] medial. Again, as in proposition 105 we shall demonstrate

[that the rectangle contained by AC, BC] is commensurable with the rectangle contained by DF, EF. Since, then, that [rectangle] is assumed rational, [this one] too will be [rational]; and in the same way as was proved in the preceding proposition, the lines DF, EF [will be] incommensurable in square [Margin: X — ?, foot-margin foxed]

(The demonstration of Prop. 107 breaks off here and continues on the following page.)

(Conclusion of the demonstration of Theor. 83 / Prop. 107, carried over from the previous page.)

incommensurable. Therefore, since DF and EF are incommensurable in square, and make the sum of their squares a medial area while the rectangle contained by them is rational, [Margin: ^a — *Elements* X.78] DE will be the line that with a rational area produces a medial whole, and so on. Which was to be demonstrated.

THEOR. 84. PROPOS. 108.

[Margin: cvij. | cij.]

A straight line commensurable with the line that produces a medial whole with a medial area itself also produces a medial whole with a medial area.

Let AB be a line that produces a medial whole with a medial area, and let BC be joined to it as its congruent part, so that AC and BC are incommensurable in square, making the sum of their squares a medial area and the rectangle under them likewise medial and, moreover, incommensurable with the sum of their squares. And let DE be commensurable with AB in any way whatever. I say that DE too is a line that produces a medial whole with a medial area.

For, the same constructions being made as those we proved above, we shall show, just as in proposition 106,

Diagram. Two horizontal line segments, one above the other, each divided into two parts.

- A (upper line, left end): start of the line AB.
- B (upper line, middle): division point; BC is the part joined on.
- C (upper line, right end): so that AC is the whole.
- D (lower line, left end): start of the commensurable line DE.

- E (lower line, middle): division point.
- F (lower line, right end): so that DF is the whole, with EF the joined part.

that the sum of the squares of AC, BC is commensurable with the sum of the squares of DF, EF. Since, then, the former is assumed to be medial, the latter too will be medial, by the corollary of proposition 24 of this book. Again, as we showed in proposition 105, the rectangle under AC, BC is commensurable with the rectangle under DF, EF. Since, then, the former is medial, the latter too will be medial, by the same corollary. Likewise, as in proposition 106, DF and EF will also be incommensurable in square. Finally, since the sum of the squares of AC, BC is commensurable with the sum of the squares of DF, EF, as has been said, and the rectangle under AC, BC is commensurable with the rectangle under DF, EF; but the sum of the squares of AC, BC and the rectangle under AC, BC are, by hypothesis, incommensurable; then, by the scholium of proposition 14 of this book, the sum of the squares of DF, EF and the rectangle under DF, EF will also be incommensurable. And so, since DF, EF are incommensurable in square, and the sum of their squares is medial, and the rectangle under them is likewise medial and incommensurable with the sum of their squares, [Margin: ^a — *Elements* X.79] DE will be the line that with a medial area produces a medial whole. A straight line commensurable, therefore, with the line that produces a medial whole with a medial area, and so on. Which was to be shown.

THEOR. 85. PROPOS. 109.

[Margin: cviiij. | ciij.]

When a medial area is subtracted from a rational area, the straight line whose square equals the remaining area is one of two irrationals: either an apotome or a minor.

Let the medial CD be subtracted from the rational AD. I say that the line whose square equals the remaining area AB is either an apotome or a minor. For let the rational EF be set out, [Margin: ^a — *Elements* I.45] and to it let the rectangle EG be applied equal to AB, and to GH let another, HI, be applied equal to CD, so that the whole EI is equal to the whole AD.

Diagram. Two rectangles standing side by side on a common base line. The left rectangle represents the given areas; the right rectangle is built on the rational line EF, to which the areas are applied.

- A (left rectangle, top-left corner): the whole area AD.
- C (left rectangle, top, internal division): marks off the part CD.

- B (left rectangle, base-left): lower-left corner.
- D (left rectangle, base): lower division.
- E (right figure, top-left): top of the rational line EF.
- H (right figure, top, internal division): between E and K.
- K (right figure, top-right): so that EK is the whole breadth.
- F (right figure, base-left): foot of the rational line EF.
- G (right figure, base, internal division): foot of the division HG.
- I (right figure, base-right): so that FI is the whole base, EI equal to AD.

Since, then, EI, being equal to the rational AD, is rational, [Margin: ^b — *Elements* X.21] EK will be rational and commensurable in length with the rational EF.

Again, since HI, being equal to the medial CD, is medial, [Margin: ^c — *Elements* X.23] HK will be rational but incommensurable in length with EF. And so, since EK is commensurable in length with EF while HK is incommensurable in length with the same EF, [Margin: ^d — *Elements* X.13] EK and HK are incommensurable in length. But they are also rational. Therefore they are rational and commensurable in square only; [Margin: ^e — *Elements* X.74] and for that reason the remainder EH is an apotome, with HK the part joined to it.

Now EK is either greater in square than HK by the square of a line commensurable with it in length, or by the square of one incommensurable. If EK is greater in square than HK by the square of a line commensurable with itself in length, and the whole EK has also been shown to be commensurable in length with the rational EF, then by definition EH will be a first apotome. Therefore the line whose square equals the area EG — contained by the rational EF and the first apotome EH, that is, the area AB equal to it — [Margin: ^f — *Elements* X.92] is an apotome. But if EK is greater in square than HK by the square of a line incommensurable with itself in length, while the whole EK has been shown to be commensurable in length with the rational EF, then by definition EH will be a fourth apotome. Therefore the line whose square equals the area EG — contained by the rational EF and the fourth apotome EH, that is, the area AB equal to it — [Margin: ^g — *Elements* X.95] is a minor. Therefore, when a medial is subtracted from a rational, and so on. Which was to be shown.

THEOR. 86. PROPOS. 110.

[Margin: cix. | civ.]

When a rational area is subtracted from a medial area, two other irrationals arise: either the first apotome of a medial, or the line that produces a medial whole with a rational area.

Let the rational CD be subtracted from the medial AD. I say that the line whose square equals the remaining area AB is either the first apotome of a medial, or the line that with a rational area produces a medial whole. For let the same constructions be made as above.

Diagram. The same arrangement as before: a left rectangle for the given areas and, to the right, the figure built on the rational line EF.

- A (left rectangle, top-left corner): the whole area AD.
- C (left rectangle, top, internal division): marks off the part CD.
- B (left rectangle, base-left): lower-left corner.
- D (left rectangle, base): lower division.
- E (right figure, top-left): top of the rational line EF.
- H (right figure, top, internal division).
- K (right figure, top-right): EK the whole breadth.
- F (right figure, base-left): foot of EF.
- G (right figure, base, internal division).
- I (right figure, base-right): EI equal to AD.

And since EI, being equal to the medial AD, is medial, [Margin: ^a — *Elements* X.23] EK will be rational but incommensurable in length with EF. Likewise, since HI, being equal to the rational CD, is rational, [Margin: ^b — *Elements* X.21] HK will be rational and commensurable in length with EF. And so, since HK is commensurable in length with EF while EK is incommensurable in length with the same EF, [Margin: ^c — *Elements* X.13] HK and EK are incommensurable in length. But they are also rational. Therefore they are rational and commensurable in square only;

[Margin: ^d — *Elements* X.74] and consequently the remainder EH is an apotome, with HK the part joined to it.

Diagram. The figure for Proposition 110 is reprinted here where its demonstration continues: a left rectangle (A, C at top; B, D at base) and, to the right, the figure on the rational line EF (E, H, K along the top; F, G, I along the base).

- A, C (left rectangle, top); B, D (left rectangle, base).

- E, H, K (right figure, top edge); F, G, I (right figure, base).

Now EK is either greater in square than HK by the square of a line commensurable with itself in length, or by the square of one incommensurable. If EK is greater in square than HK by the square of a line commensurable with itself in length, since the joined HK has been shown to be commensurable in length with the rational EF, then by definition EH will be a second apotome. Therefore the line whose square equals the area EG — contained by the rational EF and the second apotome EH, that is, the area AB equal to it — [Margin: ^e — *Elements* X.93] is the first apotome of a medial. But if EK is greater in square than HK by the square of a line incommensurable with itself in length, while the joined HK has been shown to be commensurable with the rational EF, then by definition EH will be a fifth apotome. Therefore the line whose square equals the area EG — contained by the rational EF and the fifth apotome EH, that is, the area AB equal to it — [Margin: ^f — *Elements* X.96] is the line that with a rational area produces a medial whole. Therefore, when a rational is subtracted from a medial, and so on. Which was to be shown.

THEOR. 87. PROPOS. 111.

[Margin: cx. | cv.]

When a medial area is subtracted from a medial area that is incommensurable with the whole, two other irrationals arise: either the second apotome of a medial, or the line that produces a medial whole with a medial area.

Let the medial CD, which is incommensurable with the whole AD, be subtracted from the medial AD. I say that the line whose square equals the remaining area AB is either the second apotome of a medial, or the line that with a medial area produces a medial whole. For, the same constructions being made as above:

Diagram. Again a left rectangle for the given areas and, to the right, the figure on the rational line EF.

- A (left rectangle, top-left); C (left rectangle, top, division); B, D (base).
- E (right figure, top-left); H (top division); K (top-right, EK the breadth).
- F (base-left, foot of EF); G (base division); I (base-right, EI equal to AD).

since EI and HI, being equal to the medials AD and CD, are medial, [Margin: ^a — *Elements* X.23] EK and HK will be rational but incommensurable in length with EF. And since AD, CD — that is, EI, HI — are assumed incommensurable, [Margin:

^b — *Elements* X.10] EK and HK, which have the same ratio to them, will be incommensurable in length. But they are also rational. Therefore they are rational and commensurable in square only; [Margin: ^c — *Elements* X.74] and consequently the remainder FH [recte: EH] is an apotome, with HK the part joined to it.

Now EK is either greater in square than HK by the square of a line commensurable with itself in length, or by the square of one incommensurable. If EK is greater in square than HK by the square of a line commensurable with itself in length, since neither of them, EK, HK, has been shown to be commensurable in length with the rational EF, then by definition EH will be a third apotome. Wherefore the line whose square equals the area EG — contained by the rational EF and the third apotome EH, that is, the area AB equal to it — [Margin: ^d — *Elements* X.94] is the second apotome of a medial. But if EK is greater in square than HK by the square of a line incommensurable with itself in length, since neither of them, EK, HK, is commensurable in length with the rational EF, as we have demonstrated, then by definition EH will be a sixth apotome. For which reason the line whose square equals the area EG — contained by the rational EF and the sixth apotome EH, that is, the area AB equal to it — [Margin: ^e — *Elements* X.97] is the line that with a medial area produces a medial whole. Therefore, when a medial is subtracted from a medial, and so on. Which was to be demonstrated.

THEOR. 88. PROPOS. 112.

[Margin: cxj. | cvj.]

An apotome is not the same as a binomial.

Let A be any apotome. I say that A is not the same as a binomial. For, if it be possible, let A be some binomial. Let the rational BC be set out, [Margin: ^a — *Elements* I.45] and to BC let there be applied the rectangle CD equal to the square on A. Since, then, A is an apotome, [Margin: ^b — *Elements* X.98] the breadth BD will be a first apotome.

Diagram. At the top, a short segment A (the apotome). Below it a straight line B–F–D–E, divided at F and at D; from B a rectangle descends to C at the lower left (the rectangle CD, equal to the square on A, applied to the rational BC).

- A (top, short segment): the apotome under discussion.
- B (line, left end): also upper-left corner of the applied rectangle.
- F (line, first division): greater term BF of the supposed binomial.

- D (line, second division): breadth-boundary BD.
- E (line, right end): DE the part joined to the first apotome.
- C (lower-left corner of the rectangle below B).

Let DE, then, be joined to it. Therefore, by the definition of the first apotome, BE and DE will be rational and commensurable in square only; BE will be greater in square than DE by the square of a line commensurable with itself in length; and BE itself will be commensurable in length with the rational BC. Again, since A is also assumed to be a binomial, [Margin: ^c — *Elements* X.61] the same breadth BD will be a first binomial. Let its greater term be BF. Therefore, by the definition of the first binomial, BF and FD will be rational and commensurable in square only; BF will be greater in square than FD by the square of a commensurable line; and BF will be commensurable in length with the rational BC. And so, since both BE and BF are commensurable in length with the same BC, [Margin: ^d — *Elements* X.12] BE and BF will also be commensurable in length with one another. Therefore, since the whole BE is commensurable in length with the part BF, the same BE will also be commensurable in length with the remaining part FE, by the corollary of proposition 16 of this book; and so, since BE is rational, FE too will be rational. But since, of the two lines BE, FE commensurable in length, BE itself is incommensurable in length with DE (because BE, DE are rational and commensurable in square only), [Margin: ^e — *Elements* X.14] the other, FE, will also be incommensurable in length with DE. But both FE and DE have been shown to be rational. Therefore FE, DE are rational and commensurable in square only. Wherefore the remainder FD [Margin: ^f — *Elements* X.74] is an apotome, and so is irrational. But it has also been shown to be rational. Which is absurd. Therefore A, being an apotome, is not the same as a binomial. Which was to be demonstrated.

COROLLARIUM.

From what has been demonstrated it will also be easy to gather that the apotome and the other irrational lines that follow it are neither the same as the medial nor the same as one another.

For the square of the medial, applied to the rational line, [Margin: ^g — *Elements* X.23] produces as its breadth a rational line incommensurable in length with the rational itself.

But the square of the apotome, applied to the rational, [Margin: ^h — *Elements* X.98] produces as its breadth a first apotome.

And the square of the first apotome of a medial, applied to the rational, [Margin: ⁱ — *Elements* X.99] produces as its breadth a second apotome.

The square of the second apotome of a medial, applied to the rational, [Margin: ^k — *Elements* X.100] produces as its breadth a third apotome.

Then the square of the minor, applied to the rational, [Margin: ^l — *Elements* X.101] produces as its breadth a fourth apotome.

But the square of the line that with a rational area produces a medial whole, applied to the rational, [Margin: ^m — *Elements* X.102] produces as its breadth a fifth apotome.

Finally the square of the line that with a medial area produces a medial whole, applied to the rational, [Margin: ⁿ — *Elements* X.103] produces as its breadth a sixth apotome.

And so, since these breadths differ both from the breadth of the medial — because this one is rational, while those are irrational — and from one another — because they are not, in order, the same apotomes — it is manifest that the apotome, and the remaining irrationals that follow it, differ both from the medial and from one another.

Now since in this theorem we have demonstrated that the apotome is not the same as the binomial; and since the squares of the apotome and of the five irrationals following it in that sequence, applied to a rational, produce as breadths the first, second, third, fourth, fifth, and sixth apotome; whereas the squares of the binomial and of the remaining five irrationals that follow it, applied to a rational, produce as breadths the first, second, third, fourth, fifth, and sixth binomial; it plainly follows that the breadths of the apotome and of the other irrationals after it are not the same as the breadths of the binomial and of the remaining irrationals after it — since no apotome is the same as any binomial. Therefore both the apotome and those that follow it differ from the binomial and from those that follow it. And since both those and these differ from the medial, it follows that, given some rational line set out, there are thirteen irrational lines differing from one another, which we have discussed up to this point — namely these:

1. The medial.
2. The binomial [ex binis nominibus], of which six species have been found.
3. The first bimedial [ex binis Mediis prima].
4. The second bimedial [ex binis Mediis secunda].

5. The major [Maior].
6. The line whose square equals a rational plus a medial [Rationale ac Medium potens].
7. The line whose square equals two medials [Bina Media potens].
8. The apotome, of which likewise six species have been found.
9. The first apotome of a medial.
10. The second apotome of a medial.
11. The minor [Minor].

13. The line that with a medial area produces a medial whole [cum Medio Medium totum efficiens].

THEOR. 89. PROPOS. 113.

[Margin: cxij. | (a second, faint mark below, read as "o." — [?])]

The square of a rational, applied to a binomial, produces as its breadth an apotome whose terms are commensurable with the terms of the binomial and in the same ratio; and, moreover, the apotome so produced has the same order as the binomial.

Let A be a rational, and BC a binomial whose greater term is BD; [Margin: ^a — *Elements* I.45] and to BC let the rectangle BE be applied equal to the square on A, producing the breadth BF. I say that BF is an apotome whose terms — that is, the whole line and the part joined to it — are commensurable with the terms BD, DC of the binomial BC, and in the same ratio; and, moreover, that the apotome BF has the same order as the binomial BC.

[Margin: ^b — *Elements* I.45] For let there again be applied to DC, the lesser term, the rectangle CG equal to the same square on A, and hence to the rectangle BE, producing the breadth DG; and let BH be made equal to DG.

Diagram. At the top, a short segment A (the rational). A long horizontal line runs K–B–F–I–H, with A marked above it between B and F. Below is a rectangle with a middle horizontal level D (left)–G (right) and a base C (left)–E; vertical divisions fall at F. The applied rectangles BE and CG are shown one above the other.

- A (top, short segment): the rational line.
- K (far left of the horizontal line): left extremity.
- B (horizontal line): term-boundary; upper-left of rectangle BE.

- F (horizontal line): breadth BF of the apotome.
- I (horizontal line): with FI set equal to FB.
- H (right end of the horizontal line): so that HF, HK are formed.
- D (middle level, left): boundary DG / DC.
- G (middle level, right): so that CG is the applied rectangle.
- C (base, left): lower-left corner.
- E (base): lower boundary of BE.

And since BE, CG are equal, [Margin: ^c — *Elements* VI.14 or 16] as BC is to DC, so is DG — that is, its equal BH — to BF. And *separando*, as BD is to DC, so is HF to FB. But BD is greater than DC. Therefore HF too is greater than FB. Let FI be set equal to FB; [Margin: ^d — *Elements* VI.12] and let it be contrived that as HI is to IF, so is FB to BK. Therefore, *componendo*, as HF is to IF — that is, to its equal BF — so is FK to BK. But it has been shown that as HF is to BF, so is BD to DC. Therefore, as BD is to DC, so also will FK be to BK. But BD, DC (since they are the terms of the binomial BC) are rational and commensurable in square only. [Margin: ^e — *Elements* X.10] Therefore FK, BK too are commensurable in square only.

Again, since as HF is to BF, so is FK to BK, [Margin: ^f — *Elements* V.12] HF, FK — the antecedents taken together, namely the whole HK — will also be to BF, BK — the consequents taken together, that is, to the whole FK — as FK is to BK. And for that reason FK is a mean proportional...

(Proposition 113 continues into the following pages.)

(Continuing the proof of Prop. 113, completing the catchword "nalis" [rationalis] of the previous page.)

and so it is a rational mean proportional lying between HK and BK. Therefore, as HK (the first) is to BK (the third), so — by the corollary to VI.20 — the square on HK (the first) is to the square on FK (the second).

Now since CG is rational (for it is equal to the square on the rational A), when it is applied to the rational DC it produces [Margin: ^g — *Elements* X.20] DG as a rational breadth, commensurable in length with DC. HB too, being equal to DG, will be rational and commensurable in length with DC. And since it has been shown that as BD is to DC, so FK is to BK, while as FK is to BK, so HK is to FK, it follows that as BD is to DC, so HK is to FK. [Margin: ^h — *Elements* VI.22] Therefore, as the square on BD is to the square on DC, so the square on HK is to the square on FK. But the square on BD is commensurable with the square on DC (since the straight lines BD, DC are rational and commensurable in square, being the terms

of the binomial BC). [Margin: i — *Elements* X.10] The square on HK will therefore also be commensurable with the square on FK. But it was shown that as the square on HK is to the square on FK, so is the straight line HK to BK. [Margin: k — *Elements* X.10] Therefore HK is commensurable in length with BK, and hence also with the remaining part BH, by the corollary to Proposition 16 of this book.

But BH was shown to be rational. Therefore HK, being commensurable with it, is likewise rational; and consequently BK too, being commensurable with HK, is rational. Since, then, FK was shown to be commensurable with BK in square only, FK will also be rational. Therefore, since FK and BK are rational and were shown to be commensurable in square only, [Margin: l — *Elements* X.74] the remainder BF is an apotome, and BK is the straight line annexed to it. Which is the first point.

Now since the whole straight line HK was shown to be commensurable in length with its part BK, [Margin: m — *Elements* X.16] BK and BH will therefore also be commensurable in length with one another. And since BH was shown commensurable in length with DC, BK too — by the scholium to Proposition 12 of this book — will be commensurable in length with that same DC. Again, since it was proved that as BD is to DC, so FK is to BK, then, alternately, as BD is to FK, so DC is to BK. But DC and BK have just been shown commensurable in length; [Margin: n — *Elements* X.10] therefore BD and FK will also be commensurable in length. And so, since FK is commensurable in length with BD, and BK with DC, the terms FK, BK of the apotome BF will be commensurable in length with the terms BD, DC of the binomial BC. Which is the second point.

Likewise, since we have proved that as BD is to DC, so FK is to BK, standing in the same ratio as the terms BD, DC of BC, the terms FK, BK of the apotome are in the same ratio as the terms of the binomial BC. Which is the third point.

Finally, BD is greater in square than DC either by the square on a straight line commensurable with itself in length, or by the square on one incommensurable with it. If BD is greater in square than DC by the square on a line commensurable with it in length — since as BD is to DC, so FK is to BK — [Margin: o — *Elements* X.15] FK too will be greater in square than BK by the square on a line commensurable with it in length. And if BD is greater in square than DC by the square on a line incommensurable with it in length, then FK too will be greater in square than BK by the square on a line incommensurable with it. And if BD is commensurable in length with the assigned rational line, then FK — which was shown commensurable in length with BD — will also be commensurable in length with that same rational line, by what we proved in the scholium to

Proposition 12 of this book. But if DC is commensurable in length with the rational line, then by the same reasoning BK too will be commensurable in length with it. And finally, if neither BD nor DC is commensurable in length with the rational line, [Margin: p — *Elements* X.14] then neither FK nor BK will be commensurable in length with the rational line. The apotome BF is therefore of the same order as the binomial BC, as is clear from the second and third sets of definitions. Which is the fourth point.

Therefore the square of a rational line applied to a binomial [produces an apotome as breadth], etc. Which was to be demonstrated.

Diagram. The figure for Proposition 113. A short horizontal segment (with a tick mark) labelled A sits above the main line — the rational line. Beneath it a long horizontal straight line runs from K at the far left through the points B, F, and (near the right end) two close marks read as I and H. Below the line a rectangle is drawn, its top-left corner D and top-right corner G, its bottom-left corner C and a division mark E along the bottom; verticals descend from B and F into the rectangle.

- A (short segment, above): the rational line A
- K (far left of main line): terminus
- B, F (on main line): division points
- I, H (near right end of main line): division points
- D (rectangle, top-left): corner of the square/rectangle figure
- G (rectangle, top-right): corner
- C (rectangle, bottom-left): corner
- E (rectangle, bottom, mid): division point

THEOR. 90. PROPOS. 114.

[Margin: cxiiij. / o.]

The square of a rational line applied to an apotome produces as its breadth a binomial whose terms are commensurable with the terms of the apotome and in the same ratio; and moreover the binomial so produced has the same order as the apotome itself.

Let A be a rational line and BC an apotome, to which CD is the annex; and to BC let a rectangle CE be applied, [Margin: a — *Elements* I.45] equal to the square on A, producing BE as its breadth. I say that BE is a binomial whose terms are

commensurable with the terms BD, CD of the apotome BC and in the same ratio; and moreover that BE, the binomial, is of the same order as the apotome.

[Margin: b — *Elements* I.45] For let there again be applied to the whole BD a rectangle BF, equal to the same square on A — that is, equal to CE — producing the breadth BG. And since BF and CE are equal, [Margin: c — *Elements* VI.14 or 16] as BE is to BG, so BD is to BC; and, by conversion of the ratio, as BE is to GE, so BD is to CD. Let EG also be cut at H in the ratio of BE to GE, by the method we set out in the scholium to VI.10, so that EH is to HG as BE is to GE. Since, then, as the whole BE is to the whole GE, so EH (cut off from BE) is to HG (cut off from GE), the remainder BH of BE will be to the remainder HE of GE as the whole BE is to the whole GE. But it was shown that as BE is to GE, so EH is to HG. Therefore, as BH is to HE, so EH is to HG; and hence HE is the mean proportional between BH [recte; printed BG] and GH. Therefore, as BH (the first) is to GH (the third), so — by the corollary to VI.20 — the square on BH (the first) is to the square on HE (the second).

Now since it was shown that as BD is to CD, so BE is to GE — that is, as BH is to HE — and since BD, CD, being the terms of the apotome BC, are rational and commensurable in square only, [Margin: d — *Elements* X.10] BH and HE too will be commensurable in square only. [Margin: e — *Elements* X.10] Therefore the straight lines BH, GH — having, as we proved, the same ratio as the squares on BH and HE — are commensurable in length; and therefore the whole BH, being commensurable in length with the part GH, will also be commensurable in length with the remaining part BG, by the corollary to Proposition 16 of this book. But since BD is rational — namely the greater term of the apotome BC — and the rectangle BF, being equal to the square on the rational line A, is rational, [Margin: f — *Elements* X.20] the breadth BG will be rational, commensurable

in length with BD. Therefore, by the scholium to Proposition 12 of this book, BH too is commensurable in length with the rational BD, and so is itself rational — since BH and BG were shown commensurable in length. And since BH, HE were shown commensurable in square only, and BH is rational, HE too, being commensurable with it, is rational. So BH and HE are rational and commensurable in square only; [Margin: h — *Elements* X.37] and therefore BE is a binomial. Which is the first point.

Now since we showed that as BH is to HE, so BD is to CD, and hence, alternately, as BH is to BD, so HE is to CD; and since BH was shown commensurable in length with BD, [Margin: i — *Elements* X.10] HE too will be commensurable in length

with CD. Therefore BH, HE, the terms of the binomial BE, are commensurable in length with the terms BD, CD of the apotome BC. Which is the second point.

Indeed they are also in the same ratio, since it was proved that as BH is to HE, so BD is to CD. Which is the third point.

Finally, BD is greater in square than CD either by the square on a line commensurable with it in length, or by the square on one incommensurable with it. If it is greater by the square on a line commensurable in length, [Margin: k — *Elements* X.15] then BH too will be greater in square than HE by the square on a line commensurable with it in length. And if BD is greater in square than CD by the square on a line incommensurable in length, then BH too will be greater in square than HE by the square on a line incommensurable with it. And if BD is commensurable in length with the assigned rational line, then BH too, being commensurable in length with BD, will be commensurable with that same rational line, by the scholium to Proposition 12 of this book. But if CD is commensurable in length with the rational line, then HE too will be commensurable in length with it. And if neither BD nor CD is commensurable in length with the assigned rational line, [Margin: l — *Elements* X.14] then neither BH nor HE will be commensurable with the rational line. Therefore, by the second and third sets of definitions, the binomial BE is of the same order as the apotome BC. Which is the fourth point.

Therefore the square of a rational line applied to an apotome produces as breadth a binomial whose terms are commensurable with the terms of the apotome and in the same ratio, etc. Which was to be demonstrated.

Diagram. The figure for Proposition 114, reprinted at the head of the page. A short segment labelled A (the rational line) stands above. A horizontal line runs from B on the left through the division points G and H to E on the right. Below it a rectangle descends: C marks the left side, D the bottom-left corner, and F a mark along the bottom; dashed verticals fall from G and H.

- A (short segment, above): the rational line A
- B (line, left end): the whole
- G, H (on line): the points BG, GE cut at H
- E (line, right end): terminus
- C (rectangle, left side): division point
- D (rectangle, bottom-left): corner
- F (rectangle, bottom): division mark

THEOR. 91. PROPOS. 115.

[Margin: cxiv. / o.]

If an area is contained by an apotome and a binomial line whose terms are commensurable with the terms of the apotome and in the same ratio, then the straight line whose square equals the area is rational.

Let the area AB be contained by the apotome AC and by the binomial CB, whose terms CD, DB are commensurable with the terms CE, AE of the apotome AC and in the same ratio — namely, CD is to DB as CE is to AE. Let F be the straight line whose square equals the area AB. I say that F is rational.

For, with a rational line G assigned, [Margin: a — *Elements* I.45] let there be applied to the binomial CB a rectangle CH equal to the square on G. [Margin: b — *Elements* X.113] Then the breadth BH will be an apotome, whose terms HI, BI are commensurable in length with the terms CD, DB and in the same ratio — namely, HI is to BI as CD is to DB, and hence as CE is to AE; and, alternately, as the whole HI is to the whole CE, so the part cut off BI is to the part cut off AE. [Margin: c — *Elements* V.19] Therefore the remainder BH will be to the remainder AC as the whole HI is to the whole CE. [Margin: d — *Elements* X.12] But HI is commensurable in length with CE, since each of HI, CE was commensurable in length with CD. [Margin: e — *Elements* X.10] Therefore BH too is commensurable in length with AC. [Margin: f — *Elements* X.10] And on that account HC too will be commensurable with BA, [Margin: g — *Elements* VI.1] since as HB is to AC, so HC is to BA. But HC, being equal to the square on the rational G, is rational. Therefore BA too, being commensurable with it, will be rational; and consequently the line F, whose square equals BA, will be rational.

Therefore, if an area is contained by an apotome and a binomial whose terms are commensurable with the terms of the apotome and in the same ratio, the straight line whose square equals the area is rational. Which was to be demonstrated.

Diagram. The figure for Proposition 115. Two short segments at the top are labelled F and G (the line F and the rational line G). Below runs a horizontal line marked E, A, C (with B at the right, less legible). Beneath it a rectangle is drawn, with a division point D in the interior and H at the lower right corner.

- F (top segment): the line whose square equals the area
- G (top segment): the rational line
- E, A, C (on line): E the terminus, A and C the ends of the apotome AC and binomial CB

- D (rectangle interior): division point
- H (rectangle, lower right): breadth-point
- (B, I: named in the text but not clearly legible on the figure)

COROLLARIUM.

From this it is clear that a rational area can be contained by two irrational straight lines. For the area AB, contained by the apotome AC and the binomial CB — which are irrational — has been shown to be rational.

SCHOLIUM.

In the last three propositions the terms of the apotome are to be understood as commensurable *in length* with the terms of the binomial. For in the first two they were shown to be commensurable in length; but in the last — namely, in this 115th — nothing will follow if the terms CD, DB are supposed to be commensurable only *in square* with the terms CE, AE. This is readily apparent from the demonstrations of these three propositions.

THEOR. 92. PROPOS. 116.

[Margin: cxv. / cvij.]

From a medial line infinitely many irrational lines arise, and none of them is ever the same as any of the preceding ones.

Let AB be a medial line. I say that from it infinitely many irrational lines arise, none of which is the same as any of the thirteen preceding ones treated in the corollary to Proposition 112 of this book. For, with a rational line AC assigned, let the area AD be contained by the medial AB and the rational AC. Then AD, being an area contained by the rational AC and the irrational AB, is irrational, by the lemma to Proposition 38 of this book. Let BE be the straight line whose square equals it; by Definition 11 it will be irrational. I say that BE is

not the same as any of those thirteen which we collected in the corollary to Proposition 112 of this book. [Margin: a — *Elements* X.23] For since the square on the medial line, applied to the rational AC, produces a breadth that is rational but incommensurable in length with AC; and the squares of the remaining twelve irrationals, applied to the same rational AC, produce breadths that are either binomials or apotomes, as is clear from Propositions 61, 62, 63, 64, 65, 66, 98, 99, 101, 102, 103 of this book; but the square of this irrational BE, applied to the same rational AC, produces AB, a medial breadth — it is evident that the irrational BE

differs from all those thirteen, since its square, applied to the rational line, produces a breadth different from the breadths that the squares of those thirteen lines produce when applied to the same rational line.

And if the rectangle DE is completed, it too, being contained by the rational BD and the irrational BE, will be irrational, by the said lemma to Proposition 38. Let EF be the straight line whose square equals it; by Definition 11 it will be irrational. I say again that EF is not the same as any of those thirteen, nor even as BE itself. This is evident, since the square on EF, applied to the rational line, produces the breadth BE. But the squares of those thirteen, and the square of BE itself, produce — when applied to the same rational line — breadths different from BE, as was demonstrated. In the same way infinitely many other irrationals will be found, differing both from one another and from those already named. Therefore from a medial line infinitely many irrationals arise, etc. Which was to be demonstrated.

Diagram. The figure for Proposition 116, a rectangle divided by vertical lines into panels (the areas AD and DE). The engraved labels are badly foxed and mostly illegible; along the top edge, division marks that read as D[?] and E[?] can be made out, with a further mark F[?] toward the right, and the left side bears tick marks. — labels at the resolution floor.

- (top edge, left–right): A[?], D[?], E[?], F[?] — division points of the rectangles AD and DE
- (left side): tick marks, labels illegible [?]

THEOR. 93. PROPOS. 117.

[Margin: cxviii. / vij.]

Let it be proposed to show that in square figures the diagonal is incommensurable in length with the side.

Let ABCD be a square, in which AC is the diagonal. I say that the diagonal AC is incommensurable in length with the side AB. For if it is not incommensurable, it will be commensurable in length; [Margin: a — *Elements* X.5] and therefore AC and AB will have to one another the ratio of a number to a number. Let AC have to AB the ratio that the number EF has to the number G, and let the numbers EF and G be the least of all having the same ratio. Since, then, as AC is to AB, so the number EF is to the number G, it follows that as the square on AC is to the square on AB, so the square number from EF is to the square number from G. [Margin: b — *Elements* VI.20 & VIII.11] (For since squares have the duplicate ratio of their

sides, and the sides have equal ratios, the ratios of the squares will also be equal, being duplicates of equal ratios.)

But the square on AC is double the square on AB, by what we showed in the scholium to Proposition 47 of Book 1. Therefore the square number from EF will also be double the square number from G; and consequently the square from EF, having a half — that is, being divisible into two equal parts — will be even, by definition. Therefore EF too, which produces it, will be even. (For if it were odd, then — since, multiplying itself, it produces its own square — the square would itself be odd, [Margin: c — *Elements* IX.29] because an odd number multiplying an odd number produces an odd number. But that is absurd, since it was shown to be even.)

Now since EF and G are the least in their ratio, [Margin: d — *Elements* VII.24] they are prime to one another; and since EF was shown to be even, G will be odd. (For if it too were even, the number two would measure both EF and G, and so they would not be prime to one another — which is absurd.) Now let the even number EF be bisected at H. Since, then, the number EF is double the number EH, [Margin: e — *Elements* VIII.11] and squares have the duplicate ratio of their sides, the square on EF will be quadruple the square on EH. (For the quadruple ratio is the duplicate of the double ratio, as appears in these numbers: 4, 2, 1.) And so, since the square from EF is double the square from C [recte: G] and quadruple the square from EH: of the 4 equal parts making up the square from EF, the square from G will be 2 such parts, and the square from EH 1 such part. Therefore the square from G is double the square from EH, since its ratio to it is that of 2 to 1; and hence, as we said above of the number EF, the square from G, having a half, will be even, and G itself will also be even. But it was also shown to be odd. Which is absurd. Therefore the diagonal AC is not commensurable in length with the side AB. Hence it is incommensurable in length.

Diagram. The figure for Proposition 117. A square ABCD is drawn: A at the top-left, B at the top-right, C at the bottom-right, D at the bottom-left, with the diagonal AC drawn across it. Below the square lies a straight segment with terminal points E (left) and F (right), bisected at the mid-point H (the intervening length shown by a row of dots); beneath this a shorter dashed segment is labelled G — representing the numbers EF (bisected at H) and G.

- A (square, top-left): vertex; endpoint of the diagonal AC
- B (square, top-right): vertex
- C (square, bottom-right): vertex; endpoint of the diagonal AC
- D (square, bottom-left): vertex

- E, F (lower segment, ends): the number EF
- H (lower segment, middle): bisection point of EF
- G (dashed segment): the number G

Alternatively. Suppose, if it be possible, that the diagonal AC is commensurable in length with the side AB; and let AC, AB have the ratio of the numbers EF and G, which are the least in their ratio, and hence prime to one another. Then G will not be unity. (For since the square on AC is double the square on AB, and since — as we said in the former demonstration — the square on AC is to the square on AB as the square number from EF is to the square number from G, the square from EF will also be double the square from G. If, then, G is unity — and hence its square also unity — the square from EF will be two. Which is absurd.) Therefore G is a number [greater than unity]. And since, as has now been demonstrated, the square from EF is double the square from G, the square from G will measure the square from EF; [Margin: f — *Elements* VIII.14] and therefore the side G too will measure the side EF. Since, then, G also measures itself, the numbers EF and G will be composite with respect to one another, having a common measure, the number G. But they are also prime to one another. Which is absurd. Therefore the diagonal AC is not commensurable in length with the side AB. And so we have shown that in square figures the diagonal is incommensurable in length with the side. Which was to be demonstrated.

SCHOLIVM.

But we shall also prove this same theorem affirmatively, in this way. Since, from what we demonstrated in the scholium to Proposition 47 of Book 1, the square described on the diagonal is double the square described on the side, the square on the diagonal will have to the square on the side the ratio 2 to 1, or 4 to 2, or 8 to 4, and so on. And since, when any number of terms whatever are taken in double proportion starting from uni[ty...]

taken in double proportion from unity—1, 2, 4, 8, 16, 32, 64, and so on—only the third from unity is a square, [Margin: g — *Elements* IX.10] and all the others each skip one over, since the first from unity, namely 2, is not made a square; only these numbers 4, 16, 64 will be squares, while the rest, 2, 8, 32, are not squares. Therefore, since 4 is a square and 2 is not, 4 will not have to 2 the ratio which a square has to a square [Margin: h — *Elements* VIII.24] (otherwise 2 too would be a square). And for that reason neither will the square on the diagonal have to the square on the side the ratio which a square number has to a square number. Therefore the diagonal is incommensurable in length with the side itself. [Margin: i — *Elements* X.9] Which was what was proposed.

We have also demonstrated this theorem otherwise at the end of definition 8 of book 5, in the scholium of proposition 8 of book 8, and in the scholium of proposition 9 of this book.

In the Greek copies, however, a certain appendix is found at this point, the understanding of which depends on the following books of stereometry, so that it might reasonably be omitted. But since it contains a doctrine not to be despised, bearing on the commensurability and incommensurability of all magnitudes, I have thought it well to explain it briefly, noting in the margin—as is my usual practice—the passages of stereometry needed for the demonstration of what is said here. Here, then, is the appendix.

Once straight lines incommensurable in length have been found, very many other magnitudes—both plane and solid—will be found to be incommensurable with one another. For let A and C be straight lines incommensurable with one another in length, and let B be the mean proportional between them. Then, since by the corollary of VI.20 as A is to C, so is any rectilinear figure constructed on A to a rectilinear figure similar and similarly situated on B, and since A and C are incommensurable in length, [Margin: k — *Elements* X.10] those rectilinear figures on A and B will be incommensurable.

Diagram. Three parallel horizontal line segments, labelled from top to bottom, illustrating the incommensurable lines and their mean proportional.

- A (top segment): the first straight line
- C (middle segment): the second straight line, incommensurable in length with A
- B (bottom segment): the mean proportional between A and C

Again, since circles whose diameters are A and B have the ratio which the squares described on A and B have, [Margin: l — *Elements* XII.2] and these squares, being similar rectilinear figures similarly situated, have the ratio which A has to C by the corollary of VI.20, [Margin: m — *Elements* V.11] the circles of the diameters A and B will also have the same ratio as A to C. But A and C are incommensurable in length. [Margin: n — *Elements* X.10] Therefore the circles of the diameters A and B are incommensurable as well.

Now if solids are constructed—pyramids, that is, or prisms of the same height, whose bases are similar rectilinear figures similarly described on A and B— [Margin: o — *Elements* XII.5, 6, or 7] the pyramids and prisms will have the same ratio as their bases, that is, as those rectilinear figures. Therefore, since those rectilinear figures are incommensurable, as has just been demonstrated, [Margin:

p — *Elements* X.10] the solids themselves—the pyramids and prisms—will also be incommensurable.

But if cones or cylinders of equal height are built whose bases are the circles of the diameters A and B, [Margin: q — *Elements* XII.11] such cones and cylinders will have the same ratio as their bases, that is, as those circles. Since, then, the circles have been shown to be incommensurable, [Margin: r — *Elements* X.10] the said cones and cylinders will also be incommensurable. Thus there have been found not only lines and surfaces that are incommensurable, but also bodies, or solids, that are incommensurable. Which was what was proposed.

By the same reasoning, if the straight lines A and B are commensurable in length, [Margin: s — *Elements* X.10] we shall show that their similar rectilinear figures, similarly described, and likewise their circles, are commensurable, [Margin: t — *Elements* XII.5, 6, 7 & 11] and hence also their pyramids and prisms, and finally their cones and cylinders—provided only that they have the same height, as is evident.

FINIS ELEMENTI DECIMI.

EVCLIDIS ELEMENTVM VNDECIMVM

Et Solidorum primum.

(Euclid's Eleventh Element, and the First of the Solids.)

DEFINITIONES.

I.

A solid is that which has length, breadth, and thickness.

In the previous six books Euclid discussed at length that part of geometry which deals with plane figures, and which has taken the name "geometry" as though it were its own; in the three books that followed he carefully taught those properties of numbers that seemed necessary for understanding the doctrine of commensurable and incommensurable lines, a doctrine which he then set out most clearly in the tenth book, so that the construction and nature of the five regular solids—treated most subtly in the last three books, namely in 13, 14, and 15—might be more fully understood. Now at last, in this eleventh book, he takes up that part of geometry which considers bodies, or solids, and which by its proper name is called stereometry.

First, as is his custom, he explains the terms most necessary to the subject, the first of which is "solid," or "body"—namely the third kind of quantity. He teaches, then, that the quantity which, besides length and breadth, has also received thickness or depth, so as to possess three dimensions—one along its length, another along its breadth, and a third along its depth, thickness, or height—is called a solid or body; just as the quantity having only length is called a line, and that which adds breadth to length is called a surface, as we said in the first book.

Furthermore, just as mathematicians, so that we may rightly grasp a line, bid us imagine some point moved from place to place—for this describes a trace that is merely long, that is, a line, since a point is wholly without magnitude—and, so that we may perceive a surface, advise us to imagine some line moved crosswise—for this will describe a trace that is only long and broad: long because of the length of the line, broad because of that crosswise motion, but without depth, since the line too lacks it—so likewise, to set a body or solid before our eyes (that is, a quantity endowed with three dimensions), they counsel us to conceive some surface raised uniformly, or moved crosswise. For in this way there will be described a trace that is long, broad, and deep: long and broad because of the surface, which is long and broad, and deep or thick because of that raising, or motion, of the surface. This quantity, then, is called a solid or body. Nor can any fourth quantity be found distinct from line, surface, and body, since only a threefold dimension can be assigned—as was clearly demonstrated by us from Ptolemy, in his little book *On the Analemma* [de Anatemmate; recte: *de Analemmate*], in the commentary we wrote on the *Sphere* of Johannes de Sacrobosco.

II.

The boundary of a solid is a surface.

Just as a finite line has points at its ends, while a surface receives lines as its boundaries, as he taught in the first book, so now he says that the boundary of a finite solid is a surface. For since a solid or body is produced by that imaginary motion of a surface, it is evident that its outermost parts are surfaces.

III.

A straight line is at right angles to a plane when it makes right angles with all the straight lines that touch it and that lie in the plane in question.

When a straight line AB stands on a plane CD in such a way that the point B is elevated, outside the plane CD, while the point A is in the plane itself, then finally it is called a straight line—or perpendicular—to the plane CD, when it makes right angles with the lines AE, AF, AD, AG, and with all the others that, lying in the same plane, touch it at the point A. For in this way it comes about that AB stands equally on the plane CD, and inclines no more to one side than to another. For when the straight line DA is produced to H, since the angle BAD is assumed to be right, the adjacent angle BAH will likewise be right, and therefore equal to it. And by the same reasoning, any line whatever drawn out in the plane CD will make with AB two equal angles. And for that reason it will stand evenly on the plane itself. But if it could happen that AB failed to make a right angle with some one line drawn from A in the plane CD, even though it made a right angle with all the others, AB would not be called perpendicular to the plane CD. And so, when some line is granted to be perpendicular to a plane, it must also be granted that it makes right angles with all the lines drawn in the same plane that touch it. And conversely, in order that it may rightly be concluded that some line is perpendicular to a given plane, it must first be demonstrated that it makes right angles with all the lines drawn in the same plane that touch it.

Diagram. A parallelogram representing the plane CD, drawn in perspective, with a straight line rising perpendicularly from a point A in the plane to an elevated point B above it; several lines radiate from A to points on and within the plane.

- B (elevated above the plane, on a short dashed vertical): the raised end of the perpendicular AB
- A (centre of the parallelogram): foot of the perpendicular, in the plane
- C (upper-left corner of the plane)
- G (upper-right corner of the plane)
- D (lower-right corner of the plane)
- F (lower-left corner of the plane; the glyph is printed in an angular form resembling Γ/T) [?]
- E (on the left edge of the plane)
- H (between C and A, interior)
- Lines from A are drawn to E, F, D, G (and to C and H), all touching the plane at A

For a straight line standing on any plane to make right angles with the lines that touch it, it is enough that it make right angles with two lines that do not form a single line but cut one another—if they are produced. For from this it is rightly inferred that it makes right angles with all the others as well, as will be clear

from proposition 4 of this book. I said "with two that do not form a single line," because, if two lines compose a single straight line, it does not necessarily follow that a line making right angles with them makes right angles with all the others. For let the straight line AB stand on the plane CD and make right angles with two lines AE, AF drawn in the same plane, which together compose a single straight line. I say that AB does not on that account make right angles with all the others, and therefore is not perpendicular to the plane CD. This is evident, since AB can be turned about EF as an axis, so that the point B is now nearer the plane, now farther from it, and yet always makes the same right and equal angles with EF. But if that same AB makes right angles with two lines that compose an angle—such as AG, AD in the earlier figure—then at last it will make right angles with all the others, as we have said. This will be demonstrated clearly in proposition 4 of this book.

Diagram. A rectangle representing the plane CD, with a straight line BA drawn perpendicular from an elevated point B down to the centre A, and a straight line EAF drawn horizontally across the rectangle through A (the axis EF about which AB is turned).

- B (elevated above the top edge): raised end of the line BA
- A (centre): foot of the perpendicular
- C (upper-left corner of the rectangle)
- E (midpoint of the left side)
- F (midpoint of the right side)
- D (lower-right corner of the rectangle)
- EF: the axis; AE and AF compose one straight line

IV.

A plane is at right angles to a plane when the straight lines drawn in one of the planes, at right angles to the common section of the planes, are at right angles to the remaining plane.

Let the plane AB stand on the plane CD in such a way that the line AQ is elevated—that is, outside the underlying plane CD—while EB lies in that same plane. Let the common section of these planes be EB, which, as will be demonstrated in proposition 3 of this book, will be a straight line. On this line let any number of points G, I be taken; and from them, in the plane AB, let GF, IH be drawn perpendicular to the common section EB. If, then, the lines FG, HI are perpendicular to the other plane CD—that is, if they make right angles with the lines GK, GL, GM; IN, IO, IP, and with all the other lines drawn in the plane CD

from the points G and I—the plane AB will be said to be at right angles to the plane CD; because in this way it will incline no more to one side than to the other, but will stand evenly upon it. For if KG is produced to R, since the angle FGK is assumed to be right, the adjacent angle FGR will also be right, and therefore equal to it; and by the same reasoning, when any other line is drawn out in the plane CD, the angles made on both sides by the lines FG, HI will be equal. Therefore the plane AB will stand evenly on the plane CD. Accordingly, whenever some plane is granted to be perpendicular to another plane, it must also be granted that the lines drawn perpendicular to the common section in one of them are likewise perpendicular to the other plane. And conversely, in order to conclude that some plane is perpendicular to another, it must first be shown that the lines drawn perpendicular to the common section in one of them are perpendicular to the remaining plane.

Diagram. Two planes shown in perspective: a horizontal parallelogram (the plane CD) with an upright plane (the plane AB) rising along their common section EB. From points G and I on the section, lines fan out across the base plane, and perpendiculars GF, IH rise in the upright plane.

- A (top): the elevated corner of the upright plane AB (with line AQ)
- Q (upper right): the other elevated corner; AQ is the elevated line
- B (bottom of the section): lower end of the common section EB
- E (on the base, left of centre): upper end of the common section EB
- C (upper-left corner of the base plane CD)
- D (lower-right corner of the base plane CD)
- F (in the upright plane, near A): foot of perpendicular GF on the common section
- H (in the upright plane, on the right): foot of perpendicular IH on the common section [?]
- G (a point on the section EB): from it lines GK, GL, GM run in the base plane; KG produced to R
- I (a second point on the section EB): from it lines IN, IO, IP run in the base plane
- R (interior of the base): point to which KG is produced
- K, L, M (along the base, from G)
- N, O, P (along the base, from I)

V.

The inclination of a straight line to a plane is this: when a perpendicular has been drawn from the elevated end of that straight line to the plane, and a further straight line has been joined from the point which the perpendicular makes in the plane to the end of the proposed line that lies in the same plane—it is, I say, the acute angle contained by the standing line and the joined line.

Let the straight line AB stand on the plane CD, not at right angles but inclined, in such a way that the point B is elevated outside the plane, while the point A is in the plane. Then from B, the elevated end of the straight line AB, let a perpendicular BE be conceived as drawn to the same plane, making the point E in the plane; and from E to A let the straight line EA be joined. The angle BAE will necessarily be acute, [Margin: a — *Elements* I.17] since in the triangle ABE the two angles BAE, BEA are less than two right angles, and the angle BEA is right. Therefore the acute angle BAE, contained by the standing line AB and the joined line AE, is called the inclination of the straight line AB to the said plane CD; so that the inclination of the line AB to the plane CD is said to be as great as the said acute angle BAE.

Diagram. A right-angled figure showing the inclined line AB with its diagonal, the perpendicular BE dropped to the plane, and the joined line AE, the acute angle BAE marking the inclination.

- B (upper-right, elevated): raised end of the inclined line AB
- A (lower-left, in the plane): foot of the inclined line
- E (lower edge, right of A): point where the perpendicular BE meets the plane
- C (upper-left corner)
- D (lower-right corner)
- AB is the inclined (diagonal) line; BE the perpendicular to the plane; AE the joined line; angle BAE the inclination

VI.

The inclination of a plane to a plane is the acute angle contained by straight lines which, drawn in each of the planes to the same point of the common section, make right angles with the section.

(Continuation of the commentary on Definition VI — the inclination of a plane to a plane / dihedral angle.)

For let the plane CD stand upon the plane AB, so that the part toward C is elevated above the plane AB while the part toward D lies in the plane AB itself; and let CD be inclined to AB, and let DE be their common section. If then from a point F on the common section DE two perpendiculars are drawn — FG in the plane AB, and FH in the plane CD — the acute angle GFH contained by these straight lines will be called the inclination of the plane CD to the plane AB, so that the inclination of plane to plane is said to be as great as the said acute angle.

Sometimes geometers call the angle GFH the angle of inclination of the plane CD to the plane AB, whether it be acute, right, or obtuse — although properly only the acute angle exhibits the inclination of one plane to another, as Euclid teaches in this place. For a right angle indicates rather an even elevation of one plane above another than an inclination of the one to the other; and an obtuse angle indicates a kind of leaning-away of the one from the other. Nevertheless, since each of these angles shows the position, or the elevation, of one plane above another, most writers have generally called "the angle of inclination" any angle whatever that is contained by two straight lines drawn perpendicular in each of the two planes to some one common point of their section — such as the angle GFH, whether it be right, acute, or obtuse.

Diagram. The dihedral-angle figure illustrating Definition VI. An upper, tilted parallelogram (the plane CD) leans over a lower parallelogram (the plane AB); the two planes meet along the common section DE. From the point F on that section, one perpendicular FG is drawn in the plane AB and another FH in the plane CD, and the acute angle GFH is the inclination.

- C (upper-left corner of the tilted plane CD)
- H (upper-right corner of plane CD)
- A (left corner of the lower plane AB)
- G (interior foot of the perpendicular FG, in plane AB)
- E (left end of the common section DE)
- F (point on the common section from which both perpendiculars rise)
- D (right end of the common section DE)
- B (lower-right corner of plane AB)

VII.

One plane is said to be inclined to a plane similarly as another to another, when the said angles of inclination are equal to one another.

This definition is not obscure, once the preceding one is well understood. Hence one plane will be said to be more inclined to a plane when its angle of inclination is smaller, and so has receded further from a right angle.

VIII.

Parallel planes are those which do not meet one another.

Understand this of their being produced in any direction whatever, even infinitely: that is, whether to the right or to the left, and whether upward or downward, and so on. For there are some planes which meet neither when produced to the right nor to the left, yet are not on that account to be called parallel, because when drawn out upward or downward they eventually come together. For if some roof is taken whose ridge is imagined to be cut away, the two remaining planes do not meet, however far they are produced to the right and to the left; but since, extended upward, they do come together — namely at the ridge itself — they will not be called parallel.

For let there be some roof ABCDEF, contained by the two planes ABED, ACFD, whose base is BCFE; and let the ridge AGHDKI be removed. This done, it is clear that the remaining planes GBEK, HCFI do not meet one another if they are produced toward the parts GB, HC or toward the parts KE, IF; yet they are not on that account called parallel, since when produced toward the parts GH, KI they meet at the ridge AD. Therefore, in order that any planes be called parallel, it is necessary that, produced in no direction, do they meet one another.

Diagram. The "roof" (triangular-prism) figure illustrating Definition VIII. A wedge-shaped solid ABCDEF is drawn whose ridge has been cut away along AGHDKI, leaving the two upper planes GBEK and HCFI; the base is BCFE.

- A (near apex of the roof, upper-left)
- G (point on the cut, just below A)
- D (far apex of the roof, upper-right)
- K (point on the cut, just below D)
- H (left, on the cut edge)
- I (center, on the cut edge)
- B (near base vertex, center-low)
- E (far base vertex, right; faint — [?])
- C (base vertex, lower-left)
- F (base vertex, lower-center)

But just as lines lying in the same plane can be produced in only two directions — namely to the left and to the right — so two planes can be conceived as extended in four directions: leftward, rightward, upward, and downward. Accordingly any two planes are either parallel, or, produced in some direction, come together; whereas straight lines are either parallel, or, produced in one direction, meet — provided they lie in the same plane — or else are neither parallel nor ever meet, namely if they lie in different planes and are set crosswise. Hence in the definition of parallel lines in Book I this clause was added, "which, being in the same plane...", whereas here it is stated simply, "which never meet."

IX.

Similar solid figures are those which are contained by similar planes equal in number.

Euclid could have defined similar solid figures by equal angles and by the proportionality of the sides about the equal angles, as he did in defining similar plane figures. Yet he judged it better, consulting brevity, to describe them by means of similar planes equal in number — especially since from the similarity of the planes there follows at once the equality of the solid angles, as will be clear from Definition 11, since those angles are constituted by plane angles equal both in number and in magnitude; and the proportionality of the sides about the equal angles follows from the similarity of the planes.

X.

Equal and similar solid figures are those which are contained by similar planes equal in number and in magnitude.

For if the similar planes by which similar bodies are circumscribed (according to the preceding definition) are equal, each to each, such solid figures will be called not only similar but also equal. For if such solids are conceived in the mind as mutually penetrating one another, neither will exceed the other, because of the equality and similarity of the planes. For from the similarity of the planes there follows the equality of the solid angles, as we taught in the preceding definition; and from the equality of those same planes there follows the equality of the proportional sides, as we demonstrated in the lemma to Proposition 22 of Book 6. Therefore those solids will coincide with one another in every part, and so will be equal to one another.

XI.

A solid angle is the inclination, toward all the lines, of more than two lines which touch one another and are not in the same surface.

Two lines lying in the same plane which, not lying in a straight line, meet at one point make a plane angle, as we set out in Book I — such as the angle BAC contained by the two lines AB, AC set in the same plane. If now some third line AD is added which does not lie in the same plane with them, but the point D is elevated outside their plane, a solid or corporeal angle will be produced at the point A. The same would happen if a fourth line, or a fifth, or finally more were joined, though the size of the angle would vary. Now Euclid said that the lines constituting a solid angle ought not to lie in the same surface, because, namely, if the three lines AB, AC, AD lay in the same surface, no solid angle would be produced at the point A, but only a plane angle composed of the two planes BAD, DAC. But if AD is elevated — that is, outside the plane in which AB, AC lie — then the whole plane angle will no longer be composed of BAD, DAC; rather, about the point A three plane angles will stand, BAD, DAC, CAB, which, as will presently be said, constitute a solid angle. The same you will say if there are more lines, and therefore more plane angles too.

Diagram. The solid-angle figure. From the vertex A three straight lines descend to the points B (left), D (center), and C (right); the three plane angles BAD, DAC, CAB about A make up the solid angle.

- A (vertex, at the top)
- B (lower-left endpoint)
- D (lower-center endpoint)
- C (lower-right endpoint)

ALITER (*Alternatively*).

A solid angle is that which is contained by more than two plane angles not lying in the same plane, but set at one point.

This second definition of a solid angle is easy, once the preceding one is rightly understood. For since at least three lines not lying in the same plane are necessary for the constitution of a solid angle, it is clear that at a minimum three plane angles are required for a solid angle to be produced, as appears from the figure above. For the angle BAD lies in the plane in which the straight lines AB, AD lie; the angle DAC in the plane in which AD, AC lie; and finally the angle CAB in the plane in which AC, AB lie; and thus from these a solid angle is constituted

at the point A. But if three or more plane angles stand at one point, yet in the same plane, no solid angle will be constituted from them, but a certain whole plane angle, as we said above concerning lines in the same surface. Nor indeed are two plane angles sufficient to constitute a solid angle, even if they lie in different planes; for it will always gape open on one side. Hence it is necessary that at least a third surface be added, in which a third plane angle may stand. Moreover, the clearest example of a solid angle is furnished by two walls together with the floor of a house, or with the ceiling, meeting at one point. For at the very point where they come together, a solid angle is constituted from three plane angles. And here it is manifest that if one of these surfaces is removed, the solid angle is destroyed, and there remain only two surfaces inclined to one another and gaping open.

From this it will be clear to anyone that those solid angles are equal to one another which are contained by plane angles equal both in number and in magnitude. For such angles will coincide with one another if they are conceived as mutually penetrating. And just as in Book I Euclid, out of all plane angles, assumed only the rectilinear, so here, out of all angles, he defines only that one which more than two straight lines, or more than two rectilinear plane angles, comprehend. For by this definition the angle of a cone is not comprehended, which is contained by a single curved surface; nor that which is contained by two surfaces, one indeed plane and the other curved — such as the one that arises if a cone is cut through the vertex.

XII.

A pyramid is a solid figure contained by planes, set up from one plane to one point.

That is, solid figures set up from the planes ABC, ABCD, ABCDE to the points D, E, F are called pyramids. It is clear that all the planes by which a pyramid is contained are triangles, since they all converge to one point — except the plane from which they all rise, which is opposite to that point. For this can be a triangle, or a quadrilateral, or a pentagon, and so on; and from it the whole pyramid takes its name, so that it is called a triangular, quadrangular, pentagonal, or hexagonal pyramid, and so on. For each pyramid is comprehended by as many triangles as the said plane has angles or sides. Hence such a plane is usually called the base of the pyramid. Thus of a triangular pyramid, besides the base, the triangles are ABD, ACD, BCD; of a quadrangular one, ABE, ADE, BCE, CDE; and finally of a pentagonal one, ABF, AEF, BCF, CDF, EDF.

Diagram. Three pyramids illustrating Definition XII, drawn side by side.

- **Triangular pyramid:** apex D over the triangular base ABC — A (bottom-left), B (bottom-right), C (back, interior).
- **Quadrangular pyramid:** apex E over the quadrilateral base ABCD — D and C (upper back edge), A (bottom-left), B (bottom-right).
- **Pentagonal pyramid:** apex F over the pentagonal base ABCDE — E (left), D (center), C (right), A (bottom-left), B (bottom-right).

XIII.

A prism is a solid figure contained by planes, of which two opposite ones are equal, similar, and parallel, but the others are parallelograms.

That is, solid figures whose opposite planes — equal, similar, and parallel — are triangles ABC, DEF; or quadrilaterals ABCD, EFGH; or pentagons ABCDE, FGHJK, and so on; while the parallelograms are ACFD, ABED, CBEF; or ABFE, ADHE, CDHG, CBFG; or ABGF, AEKF, DEKI, DCHI, BCHG — these are called prisms. And so a prism will be nothing but a certain many-sided column of equal —

— thickness, whose opposite bases are equal, similar, and parallel, whether these be triangles, or quadrilaterals, or pentagons, and so on. Hence any prism will contain as many parallelograms as there are sides, or angles, found in each of the opposite planes, as the figures indicate.

Diagram. Three prisms illustrating Definition XIII, drawn one above another.

- **Triangular prism (top):** two triangular ends and three parallelogram faces. Vertices B (lower-left) and C (front-center) and the near apex A ([?], faint) at the left end; D (upper-right), F (right), E (lower-right) at the far end.
- **Quadrangular prism / box (middle):** near rectangle ABCD — A (upper-left), B (left), C (lower-left), D (center) — and far rectangle EFGH — E (upper-right), F (right), G (lower-right), H (far-right).
- **Pentagonal prism (bottom):** near pentagon ABCDE — A (upper-left), B (left), C (lower-left), D (bottom), E (center) — and far pentagon FGHJK — F (upper-right), G (right), H (lower-center), I (lower-right; [?]), K (far-right).

From this it is clear how greatly they are mistaken — among whom is Campanus too — who understand a prism to be only that solid figure whose two opposite planes, parallel, equal, and similar, are triangles, while the remaining three are parallelograms. This solid figure Campanus [Campanus of Novara] calls a "saw-shaped body" [Corpus serratile]. For since this figure is only one species of prism,

whereas the definition given embraces infinitely many other kinds of prism, as is evident — especially since very many demonstrations in this book and in the following (Book 12) apply equally to all prisms — it is clear that those are mistaken who gather from this definition only one kind of prism. These authors perhaps took occasion for their error from the fact that Euclid, both in the last proposition of this book and in propositions 3, 4, and 5 of Book 12, speaks only of that prism which has its two opposite planes triangles. But they did not notice that the seventh proposition of Book 12 is opposed to them, in which Euclid, speaking of a prism, makes mention of two opposite triangles because that demonstration applies only to such a prism. For if that figure alone were called a prism by Euclid, as they wish, he would have said in vain, "Every prism having a triangular base," and so on — since no other prism would exist. Indeed, in the corollary to the said seventh proposition, Theon [Theon of Alexandria] infers that a pyramid is a third part of a prism having the same base with it and the same height, although the two opposite planes of the prism are not triangles, but any other rectilinear figures, equal however and similar, as the definition requires. From which passage it is gathered still more clearly that there are infinitely many kinds of prism according to Theon, and therefore according to Euclid, since by the common opinion of all, the demonstrations ascribed to Theon are Euclid's. There is this too, that by Theon, in the demonstration of Proposition 10 of Book 12, all solids are most plainly called prisms which have two opposite planes equal — whether these be triangles and squares, or many-sided — and the rest parallelograms.

XIV.

A sphere is [the figure that results] when, the diameter remaining fixed, a semicircle carried around is revolved back again into itself, to the place from which it had begun to move, the figure so described being taken in.

Just as a straight line, revolved about one of its ends which remains at rest, describes a circle, so also a semicircle, carried about one of its ends — namely about its diameter — describes the figure which geometers call a sphere. Hence, just as in a circle a point is assigned — namely that resting end — from which all the straight lines falling on the circumference are equal, because they are all equal to that revolved line: so also in a sphere a point is found — namely the middle of the resting diameter, that is, the center of the revolved semicircle — from which all the straight lines falling on the surface are equal, because they are all equal to the semidiameter of the said semicircle. Therefore, in likeness to the definition of a circle, a sphere can also be defined in this way:

A sphere is a solid figure comprehended by one surface, such that all the straight lines falling upon it from one point of those placed within the figure are equal to one another.

Cicero, in his book *On the Universe*, speaking of the world, elegantly expressed this definition in these words: "It was therefore fashioned round — which the Greeks call σφαίροειδὲς [Greek: σφαίροειδής (sphairoeidēs, "sphere-shaped")] — whose every extremity is reached from the middle by equal radii."

XV.

The axis of a sphere is that fixed straight line about which the semicircle is turned.

XVI.

The center of a sphere is the same as that of the semicircle.

XVII.

The diameter of a sphere is a certain straight line drawn through the center and terminated on both sides by the surface of the sphere.

These three definitions need no exposition, provided only this one thing be noted: that every diameter of a sphere can be an axis, if namely the sphere is revolved about it. Hence, because in the description of the sphere the motion of the sphere itself was made about the diameter of the semicircle, Euclid called that alone the axis of the sphere.

XVIII.

A cone is [the figure generated] when, one of the sides of a right triangle containing the right angle remaining fixed, the triangle is revolved about it in itself and returns to where it began to move, the figure being taken all around.

And if the revolved straight line — the one containing the right angle — is equal to the fixed side, the cone will be right-angled [Orthogonius]; if smaller, obtuse-angled [Amblygonius]; if larger, acute-angled [Oxygonius].

Commentary (Clavius). For example, if the right triangle ABC is revolved about the stationary side AB — the side containing the right angle — until it completes a full revolution, a solid figure is described. It is bounded by two surfaces: one circular and flat, which the other side about the right angle, BC, describes by its motion;

and another curved and convex, which the side AC, opposite the right angle, traces out. This solid figure is called a cone. Campanus, however, calls it a "round pyramid."

Diagram. Three cones drawn side by side, each shown as an apex above an elliptical base, illustrating the right-angled, obtuse-angled, and acute-angled cones respectively (differing in the height-to-base proportion). In each figure the apex is A, the base is drawn as an ellipse, and the base and generating triangle are lettered identically.

- A (apex, top of each cone): vertex of the cone
- C (left end of base ellipse): one endpoint of the base diameter
- D (right end of base ellipse): the other endpoint of the base diameter
- B (front/bottom of base ellipse): foot of the generating side BC

Now if the stationary side AB is equal to the revolved side BC, as in the first figure, the cone so described is called right-angled [Greek: ὀρθογώνιος (orthogōnios), "right-angled"], because the angle at the vertex A is a right angle. For when the sides AB and BC are taken as equal, the angles BAC and BCA will also be equal [Margin: a. I.5]; and since together they equal one right angle (because ABC is a right angle), angle BAC will be half a right angle. In the same way, on the opposite side, angle BAD will be half a right angle. Therefore the whole angle CAD will be a right angle.

But if the stationary side AB is smaller than the revolved side BC, as in the second figure, the cone described will be called obtuse-angled [Greek: ἀμβλυγώνιος (amblygōnios), "obtuse-angled"], because the angle at the vertex A is obtuse. For since side BC is greater than side AB, angle BAC will be greater than angle BCA [Margin: b. I.18]. And since these two together equal one right angle (because angle ABC is taken as a right angle), BAC will be greater than half a right angle. Likewise BAD will be greater than half a right angle; and so the whole angle CAD will be greater than a right angle.

Finally, if the stationary side AB is greater than the revolved side BC, as in the third figure, the cone described will be called acute-angled [Greek: ὀξυγώνιος (oxygōnios), "acute-angled"], because the angle at the vertex A is acute. For since side AB is greater than side BC, angle BCA will be greater than angle BAC [Margin: c. I.18]. Therefore, since these two together equal one right angle (because angle ABC is taken as a right angle), BCA will be greater than half a right angle, and consequently the remaining angle BAC will be less than half a right angle. In the

same way angle BAD will be shown to be less than half a right angle. Therefore the whole angle CAD will be less than a right angle.

XIX.

The axis of a cone is that stationary line about which the triangle is revolved.

Commentary (Clavius). Namely, in each of the cones described above, the axis is the stationary straight line AB.

XX.

The base of a cone is the circle described by the revolved straight line.

Commentary (Clavius). That is, the circle described by the other side about the right angle — such as BC in the figures above. For the radius of this circle is the very side that is carried around.

Euclid, however, defined only the right cone, whose axis is perpendicular to the base — not the oblique one, whose axis is not perpendicular to the base. It seemed best, following Apollonius of Perga [Apollonio Pergaeo], to bring in the general description of a cone that covers both the right and the oblique kind. This is because in Book 12 nearly the same theorems can be demonstrated for the oblique cone as Euclid demonstrated for the right one, as we shall show there. Apollonius writes as follows, at the beginning of his *Elements of Conics*:

If from some point a straight line is drawn to the circumference of a circle that does not lie in the same plane as the point, and is extended in both directions; and if, with the point held fixed, the line is carried around the circumference of the circle until it returns to the position from which it began to move: then the surface described by this straight line — a surface made up of two surfaces fitted together at the vertex, each of which increases without limit (since the straight line describing it is produced without limit) — I call a **conic surface**.

Its **vertex**, the fixed point. Its **axis**, the straight line drawn through the point and the center of the circle. A **cone** I call the figure contained by the circle and by that part of the conic surface which lies between the vertex and the circumference of the circle. The **vertex of the cone**, the point that is also the vertex of the conic surface. Its **axis**, the straight line drawn from the vertex to the center of the circle. Its **base**, the circle itself. Among cones I call those **right** whose axes stand at right angles to their bases.

And **scalene**, those whose axes do not stand at right angles to their bases.

Commentary (Clavius). Eutocius explains all this as follows, in the commentary he wrote on Apollonius. Let AB be a circle with center C, and let D be some point raised above it; join DB and produce it without limit in both directions to the points E and F. If the straight line DB is then carried along the circumference of circle AB until the point B is restored to the place from which it began to move, it will describe a surface consisting of two surfaces that touch one another at the point D. Apollonius calls this a conic surface, and it too increases without limit, since the straight line DB that describes it is produced without limit. He calls the point D the vertex of the surface, and the straight line DC its axis. A cone he calls the figure contained by the circle AB and by that surface which DB alone describes. The vertex of the cone is the point D; its axis, DC; its base, the circle AB. And if DC is perpendicular to the circle, he calls the cone right; if not, scalene.

Diagram. Two figures illustrating Eutocius's account of the double-napped conic surface. In each, a horizontal circle (drawn as an ellipse) has diameter A–B and center C; a point D stands above the circle; the line through D and B is produced upward to E and downward to F, and as DB is carried around the circle it sweeps out one nappe below D (down to the circle and toward F) and the mirror nappe above D (up toward E). The left figure shows the right (perpendicular) case; the right figure the oblique case.

- E, E (upper ends of the generating lines, above D): points on the upper nappe
- D (crossing point above the circle): vertex of the conic surface
- A (left end of the circle's diameter): endpoint of diameter AB
- C (center of the circle): foot of the axis DC
- B (right end of the circle's diameter): endpoint carried around to generate the surface
- F, F (lower ends of the generating lines, below the circle): points on the lower nappe

XXI.

A cylinder is [the figure generated] when, one of the sides of a right-angled parallelogram containing the right angle remaining fixed, the parallelogram is revolved about it and returns again into itself, back to where it began to move, the figure being taken all around.

Commentary (Clavius). For example, if the rectangle ABCD is revolved about the stationary side AB until it completes a full revolution, the figure described will be called a cylinder. It is bounded by three surfaces: two flat circular ones, which the sides AD and BC describe; and one curved surface, which the side CD describes, like that of some round column. This is why Campanus called the cylinder a "round columnn."

Diagram. An upright cylinder generated by revolving rectangle ABCD about the side AB. The top face is drawn as an ellipse with left end D, top-center A, and right end E; the bottom face as an ellipse with left end C, bottom-center B, and right end F; the vertical axis runs from A down to B.

- D (top face, left): endpoint of the upper radius / top of side AD's circle
- A (top face, center): upper end of the axis (fixed side)
- E (top face, right): endpoint of the upper circle
- C (bottom face, left): endpoint of the lower circle
- B (bottom face, center): lower end of the axis
- F (bottom face, right): endpoint of the lower circle

XXII.

The axis of a cylinder is that stationary straight line about which the parallelogram is revolved.

Commentary (Clavius). Namely, the straight line AB in the figure above is called the axis of the cylinder.

XXIII.

The bases of a cylinder are the circles described by the two opposite sides that are carried around.

Commentary (Clavius). Such as the circles described by the opposite sides AD and BC. Euclid here defines only the right cylinder — the one whose axis is perpendicular to both bases — and in Book 12 he intends to discuss only this kind. Since we ourselves intend, in that same Book 12, to set out from other geometers nearly the same theorems concerning the oblique cylinder that Euclid demonstrated for the right cylinder, it seemed best first to define the cylinder in general, following Serenus of Antinoë [Serenus Antinsensis], so as to include both the right and the oblique kind. Serenus writes as follows, at the beginning of the first book of his work *On the Section of the Cylinder*:

If the diameters of two equal and parallel circles — themselves always remaining parallel to one another and lying in the planes of the circles — are carried around their fixed centers, and at the same time a straight line joining the ends of the diameters on the same side is carried around with them, until it returns to the place from which it began to move: then the surface described by the moving straight line is to be called a **cylindrical surface**. This too can be increased without limit, when the describing line is produced without limit.

A **cylinder** is the figure contained by the parallel circles and by the cylindrical surface lying between them. The **bases** of the cylinder are those circles themselves. The **axis**, the straight line drawn through the centers of the circles. A **side** of the cylinder, a line that, being straight and lying on the surface of the cylinder, touches both bases — the same line which, carried around, describes the surface of the cylinder, as we said earlier. Among cylinders, those are called **right** whose axis stands at right angles to their bases, and **scalene**, those whose axis does not stand at right angles to their bases.

Let AB and CD be two equal and parallel circles, with centers E and F, and with their diameters AB and CD likewise parallel. Join AC and produce it without limit in both directions to the points G and H. Now if the diameters AB and CD are carried around their centers E and F in the planes of the circles, always remaining parallel, together with the straight line AC, until they return to the place from which they began to move: then the line AC will describe a certain round surface, which Serenus calls cylindrical. This too increases without limit, since the straight line AC that describes it is produced without limit. He calls a cylinder the figure ABDC, contained by the circles AB and CD and by the cylindrical surface lying between them — the surface that AC alone describes. He says the bases of the cylinder are the circles AB and CD; the axis, the straight line EF, which joins the centers of the circles; the side of the cylinder, the straight line AC. And if the axis EF is perpendicular to the bases, he calls the cylinder right; if not, scalene.

Diagram. Two cylinders, a right one and an oblique (scalene) one, drawn side by side. In each, the upper base is an ellipse with left end C, center F, right end D; the lower base an ellipse with left end A, center E, right end B; the side-lines run from the upper toward G above and from the lower toward H below, with EF as the axis. The right cylinder is upright; the second is slanted.

- G, G (top, above the upper base): upper ends of the produced side-lines
- C (upper base, left): endpoint of the upper diameter
- F (upper base, center): upper end of the axis

- D (upper base, right): endpoint of the upper diameter
- A (lower base, left): endpoint of the lower diameter
- E (lower base, center): lower end of the axis
- B (lower base, right): endpoint of the lower diameter
- H, H (bottom, below the lower base): lower ends of the produced side-lines

XXIV.

Similar cones and cylinders are those whose axes and whose base-diameters are proportional.

Commentary (Clavius). Euclid rightly derives the similarity of cones and cylinders from their axes and their base-diameters. The base-diameters show that cones and cylinders are similar in two dimensions — length and breadth — while the axes show them to be similar in depth, or height. For let ABC and EFG be two cones, and likewise two cylinders; in the cones let the axes be AD and EH, and the base-diameters BC and FG, and similarly in the cylinders. Then if the axis AD is to the axis EH as the base-diameter BC is to the base-diameter FG, both the cones and the cylinders will be called similar to one another; for on this account they are similar in length and breadth as well as in depth, as we said — that is, all three of their dimensions are proportional.

Diagram. An upright cone, a second upright cone, and two upright cylinders, drawn in a row to illustrate similar right cones and cylinders. The first cone has apex A over a base with endpoints B and C and axis-foot D; the second cone has apex E over a base with endpoints F and G and axis-foot H. The two cylinders repeat the same lettering (axes AD and EH, base-diameters BC and FG).

- A (apex of the first cone / top of the first cylinder): vertex
- B (base endpoint, first cone): end of base-diameter BC
- C (base endpoint, first cone): end of base-diameter BC
- D (center of first base): foot of axis AD
- E (apex of the second cone / top of the second cylinder): vertex
- F (base endpoint, second cone): end of base-diameter FG
- G (base endpoint, second cone): end of base-diameter FG
- H (center of second base): foot of axis EH

Or again, [they may be shown similar] because the triangles ADB and EHF, by whose revolution the cones were described, and likewise the rectangles AB and EF, whose rotations produced the cylinders, will on this account be similar to one another. For since AD is to EH as BC is to FG, so also half of BD is to half of FH

[Margin: a. V.15]; therefore AD is to EH as DB is to HF, and, alternately, AD is to DB as EH is to HF. Hence in both the triangles and the rectangles the sides about the equal angles — namely the right angles — are proportional; and therefore both the triangles and the rectangles will be similar to one another. The triangles, because triangles that have one angle equal to one angle and the sides about the equal angles proportional are equiangular [Margin: b. VI.6], and therefore have all the sides about their equal angles proportional [Margin: c. VI.5], and so are similar to one another. The rectangles, because the two remaining sides are equal to the two sides AD and DB, opposite to opposite [Margin: d. I.34], and therefore have the same proportion as these.

But if the cones or cylinders are oblique (for Euclid spoke only of right ones), they will be called similar only when their axes and their base-diameters are proportional, and the angles of inclination formed by the axes are equal — these angles being taken as was stated in the fifth definition. For let ABC and EFG be oblique cones, and likewise oblique cylinders; in the cones let the axes be AD and EH, and the base-diameters BC and FG, and similarly in the cylinders. Then if, in both the cones and the cylinders, AD is to EH as BC is to FG, and the angles of inclination ADB and EHF are equal to one another in both the cones and the cylinders, then both the cones and the cylinders will be called similar to one another. For on this account their three dimensions are proportional, as we said above; and again both the triangles ADB and EHF and the rectangles AB and EF, whose rotations produced the cones and cylinders, are similar to one another, just as we demonstrated in the case of right cones and cylinders. For the demonstration is exactly the same, since the angles ADB and EHF are taken as equal, even though they are not right angles.

Diagram. Two oblique cones and two oblique cylinders, drawn in a row to illustrate similar inclined cones and cylinders. The lettering follows the upright figure: the first cone has apex A over a base with endpoints B and C and axis-foot D; the second cone has apex E over a base with endpoints F and G and axis-foot H; the two slanted cylinders repeat the same lettering.

- A (apex of the first oblique cone / top of the first oblique cylinder): vertex
- B (base endpoint, first figure): end of base-diameter BC
- C (base endpoint, first figure): end of base-diameter BC
- D (center of first base): foot of axis AD
- E (apex of the second oblique cone / top of the second oblique cylinder): vertex

- F (base endpoint, second figure): end of base-diameter FG [the left base-endpoint of the last cylinder is printed ambiguously — possibly Γ (?)]
- G (base endpoint, second figure): end of base-diameter FG
- H (center of second base): foot of axis EH

XXV.

A cube is a solid figure contained by six equal squares.

XXVI.

A tetrahedron is a solid figure contained by four equal equilateral triangles.

XXVII.

An octahedron is a solid figure contained by eight equal equilateral triangles.

XXVIII.

A dodecahedron is a solid figure contained by twelve equal, equilateral, and equiangular pentagons.

XXIX.

An icosahedron is a solid figure contained by twenty equal equilateral triangles.

These are the five bodies that are called regular, because all the planes by which they are bounded are equal, equilateral, and equiangular, as is clear from their definitions. By some they are called the Platonic bodies, because in the *Timaeus* Plato likens the five bodies of the world — those that the philosophers call the simple bodies, namely Heaven, Fire, Air, Water, and Earth — to these five figures, as we explained more fully in our commentary on the *Sphere* of Johannes de Sacrobosco [Ioannes à Sacro Bosco]. The construction of all of them will be set out in Book 13: that of the cube in Proposition 15, of the tetrahedron in Proposition 13, of the octahedron in Proposition 14, of the dodecahedron in Proposition 17, and finally of the icosahedron in Proposition 16. There the definitions of these bodies will be grasped more plainly and more perfectly, for on a flat surface it is extremely difficult to depict them so that one may take in their true likeness and form. Nevertheless, in the proper places we will hand down thoroughly easy procedures by which anyone may make them up as solid bodies. And no regular body exists besides those five, as we will demonstrate at the end of Book 13.

Now since the parallelepiped is frequently mentioned in this Book 11, and since Book 15 deals with the mutual inscription and circumscription of the regular bodies, we have judged it necessary to explain in three definitions what a parallelepiped is, what it is for a solid figure to be inscribed in a solid figure, and what it is to be described about the same.

XXX.

A parallelepiped is a solid figure contained by six quadrilateral figures, of which the opposite ones are parallel.

Diagram. Four three-dimensional box figures illustrating Definition XXX, arranged in two rows of two. The top pair are right (rectangular) parallelepipeds; the bottom pair are oblique parallelepipeds (rhomboids). Each of the four is lettered with the same eight vertices in the same relative positions.

- F (upper rear left) and E (upper rear right): the two back-top vertices
- A (upper front left) and D (upper front right): the two front-top vertices
- G (lower rear left) and H (lower rear right): the two back-bottom vertices
- B (lower front left) and C (lower front right): the two front-bottom vertices

For instance, take a solid figure comprehended by the six quadrilaterals ABCD, DEFA, ABGF, FGHE, EDCH, HCBG, of which the opposite faces AC and FH, likewise DF and CG, likewise AG and DH, are parallel. Such figures are named parallelepipeds, as being comprehended by parallel planes; and these opposite parallel planes are equal, and similar, and parallelograms, as will be demonstrated in Proposition 24 of this book.

There are as many kinds of parallelepiped as there are of parallelogram. For if the six parallelograms are equilateral and rectangular — that is, squares — that parallelepiped is called a *cube*, and it corresponds to the square among the plane figures. But if the six parallelograms are indeed rectangular, yet not all equilateral but longer on one side, even though two are equilateral, it is called a *parallelepiped longer on one side*. If, however, there are six parallelograms that are equilateral but not all rectangular, even though two are rectangular, that parallelepiped is called a *rhombus*. And if, finally, the six parallelograms are neither all rectangular nor all equilateral — even though two are rectangular and equilateral, or rectangular only, or equilateral only — but are nonetheless parallelograms whose opposite pairs are equal, then such a parallelepiped is called a *rhomboid*. For the rest, any parallelepiped whatever can also be called a *prism*, as is clear from the definition of the prism.

XXXI.

A solid figure is said to be inscribed in a solid figure when all the angles of the inscribed figure are set either in the angles, or in the sides, or finally in the planes of the figure in which it is inscribed.

XXXII.

A solid figure is in turn said to be circumscribed about a solid figure when either the angles, or the sides, or finally the planes of the circumscribed figure touch all the angles of the figure about which it is described.

It is not necessary that the angles of the inner figure all be set in the angles, or the sides, or the planes of the outer figure, since sometimes the outer figure contains more angles, sides, or planes than the inner, and sometimes fewer. It is enough that all the angles of the inner figure touch some angles, or some sides, or finally some planes of the outer figure, so that no angle of the inner figure is left untouched by the angles, or by the sides, or finally by the planes of the outer figure.

These last two definitions will be more clearly grasped from Book 15, in which the mutual inscriptions and circumscriptions of the regular bodies are treated at length.

THEOR. 1. PROPOS. 1.

[Margin: j.]

One part of a straight line is not in a plane of reference while another part is up above.

For suppose, if it be possible, that of the straight line AB the part AC lies in the plane of reference DE, while the part CB is up above, in such a way that all the points of the part AC lie in the plane DE, but all the points of the part CB stand above the plane DE, or below it. Then in the plane DE there will be a certain straight line set in a straight continuation with AC — namely CF. Consequently the two straight lines AB and AF have the common segment AC. This is absurd, as we demonstrated in the 10th axiom [pronunciatum] of Book 1. Therefore one part of a straight line is not in a plane of reference while another part is up above. Which was to be demonstrated.

SCHOLIUM.

This is the common demonstration of the commentators. But perhaps someone will say that something is wanting in it — namely, that it be shown that there is some straight line in the plane DE set in a straight continuation with AC. For whoever grants that of the straight line AB the part AC is in the plane DE while the part CB is up above will certainly deny that another straight line can be given, set in continuation with AC in the plane DE, since he admits that the straight line CB is the one set in a straight continuation with AC [?]. Nevertheless, to one who doubts in this way the answer must be given that any finite straight line given in any plane can be produced further in that same plane in a straight continuation, since a plane surface is one that lies evenly with the lines on it — that is, one that is always extended straight and evenly, just as a straight line is. Therefore if AC is produced in the plane DE as far as F, CF will be set in a straight and direct continuation with AC. But let us now demonstrate this very thing geometrically: that in the plane DE another straight line can be given to AC which forms with it a single straight line — even though someone may say that AB too is a straight line whose part AC is set in the plane DE while its part CB is set up above.

Diagram. A rectangle representing the plane DE, crossed by a horizontal middle line, with a segment rising above it to the right.

- D (top left corner) and the top right corner (unlabelled): top edge of the plane
- G (bottom left corner) and E (bottom right corner): bottom edge of the plane
- A (left end of the middle line), C (middle point), F (right end of the middle line): the straight line lying in the plane
- B (above and to the right of F): the raised end of segment CB

[Margin: a — *Elements* I.11] For let CG be drawn in the plane DE perpendicular to AC; and in the same plane let CF be drawn perpendicular to CG. I say that CF is set in a straight and direct continuation with AC. For since AC and FC, in the same plane DE, make with the straight line CG two right angles ACG and FCG by construction, [Margin: b — *Elements* I.14] AC and FC will be set in a straight and continuous line. Therefore, even if someone should contend that AB is a straight line whose part AC is set in the plane of reference DE while its part CB is set up above, nonetheless in the same plane DE there will be another straight line — namely CF — which forms one straight line with AC; and so the two straight lines AB and AF will have the common segment AC. Which is absurd.

Diagram. A second rectangle representing the plane DE, with a middle line and a segment rising to the upper right, showing the perpendiculars of the geometric proof.

- D (top left corner) and B (top right corner)
- A (left end of the middle line), C (middle point), F (right end of the middle line)
- G (bottom, near the middle) and E (bottom right corner)

From this it follows that all the parts of any straight line whatever — that is, the whole straight line — exist in one plane.

THEOR. 2. PROPOS. 2.

[Margin: ij.]

If two straight lines cut one another, they are in one plane; and every triangle is in one plane.

Let the straight lines AB and CD cut one another at E, and on EB and ED let the points F and G be taken at random, and let the straight line FG be drawn so as to make the triangle EFG. I say that the triangle EFG is in one plane, and likewise that the straight lines AB and CD are each in one plane as well.

Diagram. Two straight lines crossing at E, forming an X, with a triangle drawn across them and internal division points.

- A (upper left) and B (lower right): endpoints of one straight line through E
- C (upper right) and D (lower left): endpoints of the other straight line through E
- E (center): the intersection point
- F (lower left, on line toward D) and G (lower right, on line toward B): the base vertices of the triangle
- H (left inside), K (right inside), I (bottom center): the internal points where the drawn lines meet

For if a certain part of the triangle EFG — namely EHIG — were in one plane, while a certain part — namely the remaining FHI — were up above, or the reverse, then the parts EH and GI of the straight lines EF and GF would likewise be in one plane, while the parts HF and IF would be up above, or the reverse. But that this cannot be has already been demonstrated above. [Margin: a — *Elements*

XI.1] And if the part EFIK of the same triangle were believed to be in one plane while the part GIK were up above, or the reverse, then by the same reasoning the parts EK and FI of the straight lines EG and FG would be in one plane, while the parts KG and IG would be up above, or the reverse. And if, finally, the part FHKG of the same triangle were granted to be in one plane while the part EHK were up above, or the reverse, then the parts FH and GK of the straight lines FE and GE would likewise be in one plane, while the parts HE and KE would be up above, or the reverse. All of these are absurd, [Margin: b — *Elements* XI.1] as has been demonstrated. Therefore the triangle EFG exists in one plane; and the same reasoning holds for every other triangle.

Now since the sides EF and EG lie in the same plane in which the triangle EFG lies, [Margin: c — *Elements* XI.1] the whole straight lines CD and AB lie in that same plane, so that some parts of them may not be said to be in the plane while other parts are up above. Therefore the straight lines AB and CD are in one plane — the very one in which we demonstrated the triangle EFG to lie. And so, if two straight lines cut one another, they are in one plane; and every triangle is in one plane. Which was to be demonstrated.

THEOR. 3. PROPOS. 3.

[Margin: iij.]

If two planes cut one another, their common section is a straight line.

Let the planes AB and CD cut one another, and let EF be their common section. I say that EF is a straight line. For if it be not believed to be straight, let the straight line EGF be drawn in the plane AB, and the straight line EHF in the plane CD. Then the straight lines EGF and EHF, since they have the same endpoints E and F, will enclose a surface. But this cannot be, as we showed in the 14th [recte: 1st?] axiom [pronunciatum] of Book 1.

as we showed in the axiom [pronunciatum] of Book 1. Therefore the common section EF will be a straight line; and consequently, if two planes cut one another, their common section is a straight line. Which was to be shown.

Alternatively. Let the planes AB and CD again cut one another, and let the endpoints of the common section be the points E and F, which are joined by the straight line EF. If, then, the straight line EF exists in both planes, the proposition is established, for it will be the common section. But if the straight line EF is said to be in neither of them, then, if the straight line EGF is drawn in one of them, the

two straight lines EF and EGF will again enclose a surface, since they have the same endpoints E and F. And if, finally, the straight line EF is believed to be in only one of the two planes, then, if the straight line EGF is drawn in the other, again the two straight lines EF and EGF will enclose a surface. This is absurd. Therefore the straight line EF is in both planes AB and CD; and so it is their common section.

Diagram. Two planes cutting one another, drawn as intersecting parallelograms, with a lens (eye) shape at the middle marking the surface that would be enclosed by the two curved sections.

- A (upper left) and C (upper, below A): the upper plane's corners
- E (left) and F (right): the endpoints of the common section, joined by the lens
- G (upper arc of the lens) and H (lower arc of the lens): the two drawn sections EGF and EHF
- D (lower right) and B (bottom right): the lower plane's corners

THEOR. 4. PROPOS. 4.

[Margin: iv.]

If a straight line stands at right angles, at their common section, to two straight lines that cut one another, then, when it is drawn through them, it will also be at right angles to their plane.

Let the straight line AB stand at right angles to the two straight lines CD and EF at their common section B. I say that AB is at right angles also to the plane which is drawn through them, that is, in which they lie. For since they cut one another at B, [Margin: a — *Elements* XI.2] they will lie in one plane — let it be CEDF. Let the straight lines BG and BH be taken equal to one another, and likewise the straight lines BI and BK; let the straight lines GK and IH be drawn; and in the same plane let the straight line LM be drawn through B, cutting the straight lines GK and IH at the points L and M. Let there also be dropped from the point A above the plane, to that same plane, the straight lines AG, AL, AK, AH, AM, AI.

Diagram. A rectangle CEDF lying in the plane of reference, with the apex A raised above the center B, and a dense web of lines joining A and B to the marked points on the plane.

- A (top apex, above the plane)

- C (upper left corner), E (upper right corner), F (lower left corner), D (lower right corner): the rectangle CEDF
- B (center of the plane): the common section
- G (upper left, inside) and I (upper right, inside)
- L (left of B) and M (right of B): where LM cuts GK and IH
- K (lower left, inside) and H (lower right, inside)

Now since the sides BG and BK of the triangle BGK are equal, by construction, to the sides BH and BI of the triangle BHI, [Margin: b — *Elements* I.15] and the angles GBK and HBI contained by them are also equal, being vertical angles at B, [Margin: c — *Elements* I.4] the bases GK and HI will be equal to one another, and the angles BKG and BIH will likewise be equal to one another.

[Margin: d — *Elements* I.15] Again, since the angles KBL and IBM, being vertical angles at B, are equal, the two angles KBL and BKL of the triangle BKL will be equal to the two angles IBM and BIM of the triangle BIM; and moreover the sides BK and BI, to which they are adjacent, are equal, by construction. [Margin: e — *Elements* I.26] Therefore the remaining sides KL and LB will also be equal to the remaining sides IM and MB.

[Margin: f — *Elements* I.4] Furthermore, since the sides AB and BG of the triangle ABG are equal, by construction, to the sides AB and BH of the triangle ABH, and the angles ABG and ABH contained by them are equal — namely right angles, by hypothesis — the bases AG and AH will also be equal. By a similar argument the straight lines AI and AK will be equal.

[Margin: g — *Elements* I.8] Further, since the sides AI and IH of the triangle AIH are equal to the sides AK and KG of the triangle AKG, and the base AH to the base AG, from what has been demonstrated so far, the angles AIH and AKG contained by the said sides will also be equal.

[Margin: h — *Elements* I.4] And so, since the sides AK and KL of the triangle AKL are equal to the sides AI and IM of the triangle AIM, and the angles AKL and AIM contained by them are also equal, as we have demonstrated so far, the bases AL and AM will likewise be equal.

[Margin: i — *Elements* I.8] Finally, since the sides AB and BL of the triangle ABL are equal to the sides AB and BM of the triangle ABM, and the base AL to the base AM, from what has been demonstrated, the angles ABL and ABM contained by the said sides will also be equal; and since they are adjacent, they will be right angles, by Definition 10 of Book 1. Therefore the straight line AB makes right

angles with the straight line LM, which touches it at B in the plane of reference. And by the same reasoning it will be shown that AB makes right angles with all the straight lines that touch it at B in that same plane — even if they are drawn between the points G and I, and K and H, provided that the straight lines GI and KH are joined; or else that the letters be arranged, as before, in the manner that appears in this figure, where the letters are the same, and yet LM is not drawn from left to right, as in the previous figure, but from the upper part toward the lower.

Diagram. A second version of the same construction: the rectangle CEDF with apex A above the center B, but with the transversal LM drawn from top to bottom rather than from left to right, and the interior letters rearranged.

- A (top, center), C (upper left corner), E (upper right corner), F (lower left corner), D (lower right corner)
- B (center of the plane)
- K (upper left, inside), L (center), G (upper right, inside)
- H (lower left, inside), M (lower center), J [?] (lower right, inside)

Therefore the straight line AB will be at right angles to the plane CEDF — which is drawn through the straight lines CD and EF — by Definition 3 of this book. If, then, a straight line stands at right angles to two straight lines that cut one another, and so forth. Which was to be demonstrated.

THEOR. 5. PROPOS. 5.

[Margin: v.]

If a straight line stands at right angles, at their common section, to three straight lines that touch one another, then those three straight lines are in one plane.

Let the straight line AB stand at right angles, at their common section — or point of contact — B, to the three straight lines BC, BD, BE that touch one another at B. I say that the three straight lines BC, BD, BE are in one plane. [Margin: a — *Elements* XI.2] For since any two of them are in one plane — because, when produced toward B, they cut one another at B — let BC and BD be in the plane FC; and, if it be possible, let the straight line BE not be set in the same plane, but up above. [Margin: b — *Elements* XI.2] Now since the two straight lines AB and BE are in one plane, because they cut one another at B, let both be in the plane AE. And since the planes FC and AE meet one another at B, when produced they will

necessarily cut one another. [Margin: c — *Elements* XI.3] Let their common section, then, be the straight line BG. Now since the straight line AB is set at right angles to the straight lines BC and BD, [Margin: d — *Elements* XI.4] it will therefore also be at right angles to the plane FC drawn through them; and consequently it will be at right angles to the straight line...

Diagram. Two planes meeting at B, drawn as intersecting parallelograms, with the vertical line AB dropping to B and the lines BC, BD, BE radiating from B.

- A (top): the upper end of the vertical line AB
- F (left, below A): a corner of the plane FC; the dashed line A–F–B runs vertically
- B (center left): the common point of contact
- E (right, middle) and G (right, below E): E on line BE, G the common section of the planes
- D (right, below G) and C (bottom right): the ends of BD and BC

LIBER XI (continued)

[Conclusion of Proposition 5]

perpendicular to the line BG, which touches it at B, by definition 3 of this book. Consequently the right angles ABE and ABG — which lie in the plane AG and are formed by the lines AB and BE — would be equal to one another, a part equal to the whole. This is absurd. Therefore, since the two lines BC and BD lie in the single plane FC, BE will not stand up out of that plane, but will lie in the same plane with them. And so, if a straight line is at right angles to three lines that touch one another mutually, and so on. Which was to be shown.

THEOR. 6. PROPOS. 6.

[Margin: vj]

If two straight lines are at right angles to the same plane, those straight lines will be parallel.

Let two straight lines AB and CD be at right angles to the same plane EF, at the points B and D. I say that they are parallel. Draw the line BD in the plane EF; then the angles ABD and CDB are right, by definition 3 of this book. Now in the same plane EF draw DG perpendicular to BD, and set it equal to AB. Then join the lines BG, GA, and AD. Since, therefore, the sides AB and BD of triangle BAD are equal to the sides GD and DB of triangle GDB by construction, and the angles they contain,

ABD and GDB, are also equal — namely right angles — the bases AD and GB will be equal.[Margin: a — 4.pri. (*Elements* I.4)] Again, since the sides AB and BG of triangle ABG are equal to the sides GD and DA of triangle GDA, and the base AG is common, the angles ABG and GDA will be equal.[Margin: b — 8.pri. (I.8)] But ABG is a right angle, by definition 3 of this book; therefore GDA will also be a right angle. And since, by the same definition, the angle GDC is likewise a right angle, the line GD will be at right angles to the three lines DB, DA, and DC. Therefore the lines DB, DA, and DC will lie in one plane[Margin: c — 5.undecimi. (XI.5)] — that is, CD will lie in the plane drawn through the lines DB and DA. But AB lies in the same plane in which DB and DA lie.[Margin: d — 2.undecimi. (XI.2)] Therefore the line CD will lie in the same plane as AB. And so, since the interior angles ABD and CDB are right, the lines AB and CD will be parallel.[Margin: e — 28.pri. (I.28)] Therefore, if two straight lines are at right angles to the same plane, and so on. Which was to be demonstrated.

Diagram. A rectangle representing the plane EF, seen in oblique perspective, with two lines standing perpendicular to it.

- A (upper left): the top of the first perpendicular
- C (upper right): the top of the second perpendicular
- E (upper-left corner of the plane rectangle)
- B (interior left, foot of AB): where the perpendicular AB meets the plane
- D (right side of the rectangle, foot of CD): where the perpendicular CD meets the plane
- G (lower center-right, on the base): the auxiliary point where DG is set perpendicular to BD
- F (lower-right corner of the plane rectangle)

The interior lines BD, DG, BG, GA, and AD are all drawn.

THEOR. 7. PROPOS. 7.

[Margin: vij]

If there are two parallel straight lines, and any points whatever are taken on each of them, the line joining these points lies in the same plane as the parallels.

On the parallels AB and CD take any two points E and F, and let the line EF join them. I say that the line EF lies in the same plane in which the parallels AB and CD lie. For suppose EF is not granted to lie in the plane of the parallels, but

outside it; then let another plane cut the surface of the parallels through the points E and F, and let the common section of these planes be EGF, which will be a straight line.[Margin: a — 3.undecimi. (XI.3)] Then the two lines EF and EGF, having the same endpoints E and F, would enclose a surface. This is absurd. Therefore the line EF will not lie outside the plane of the parallels AB and CD. And so, if there are two parallel straight lines, and any points are taken on each of them, the line joining these points lies in the same plane as the parallels. Which was to be demonstrated.

Diagram. Two horizontal parallel lines with a joining line and a bent (impossible) path between them.

- A (upper left) — E (upper center) — B (upper right): the upper parallel, with E the point taken on it
- C (lower left) — F (lower center) — D (lower right): the lower parallel, with F the point taken on it
- G (between the parallels, just above F): the vertex of the supposed second line
- The straight line EF joins E to F; the bent path E–G–F represents the absurd second common section

THEOR. 8. PROPOS. 8.

[Margin: viij]

If there are two parallel straight lines, one of which is at right angles to some plane, the other will also be at right angles to the same plane.

Let the lines AB and CD be parallel, and let CD be at right angles to the plane EF. I say that AB too is at right angles to the same plane EF. Draw the line BD in the plane EF; then, by definition 3 of this book, the angle CDB will be right. But the two angles CDB and ABD are equal to two right angles;[Margin: a — 29.pri. (I.29)] therefore ABD too will be right. Now in the plane EF draw BG perpendicular to BD, and set BG equal to CD. Then join the lines DG, GC, and CB. Since, therefore, the sides CD and DB of triangle CDB are equal to the sides GB and BD of triangle GBD by construction, and the angles they contain, CDB and GBD, are also equal — namely right angles — the bases CB and GD will be equal.[Margin: b — 4.pri. (I.4)] Again, since the sides CD and DG of triangle CDG are equal to the sides GB and BC of triangle GBC, and the base CH [recte: CG] is common, the angles CDG and GBC contained by the said sides will be equal.[Margin: c — 8.pri. (I.8)] But CDG is a right angle, by definition 3 of this book; therefore GBC too will be right. Therefore

the line GB will be at right angles to the two lines BD and BC, which cut one another at B. (For if DB and CB were produced, they would cut one another at B, on account of the angle CBD.) And accordingly it will be at right angles to the plane drawn through BD and BC.[Margin: d — 4.undecimi. (XI.4)] But the line AB lies in this same plane, because the lines BD and BC lie in the same plane in which the parallels AB and CD lie, since the points B, C, and D lie on the parallels AB and CD.[Margin: e — 7.undecimi. (XI.7)] Therefore GB will be at right angles to the line BA, by definition 3 of this book. And so, since AB is at right angles to the lines BG and BD, AB will also be perpendicular to the plane drawn through BG and BD[Margin: f — 4.undecimi. (XI.4)] — that is, to the plane EF. Therefore, if there are two parallel straight lines, one of which is at right angles to some plane, the other too will be at right angles to the same plane. Which was to be shown.

Diagram. A rectangle representing the plane EF in oblique perspective, with two perpendiculars and connecting lines.

- A (upper left): the top of the perpendicular AB
- C (upper right): the top of the perpendicular CD
- E (upper-left corner of the plane rectangle)
- B (interior left): foot of AB in the plane
- D (right side of the rectangle): foot of CD in the plane
- G (lower center): the auxiliary point where BG is set perpendicular to BD
- F (lower-right corner of the plane rectangle)

The lines BD, BG, DG, GC, and CB are drawn as the diagonals.

THEOR. 9. PROPOS. 9.

[Margin: ix]

Lines which are parallel to the same straight line, but not in the same plane with it, are also parallel to one another.

Let the lines AB and CD be parallel to EF, but not lying in the same plane as EF. I say that AB and CD are also parallel. For from any point G on the line EF let two perpendiculars be drawn to EF itself: GH lying in the plane of the parallels AB and EF, and GI lying in the plane of the parallels CD and EF. Since, therefore, EG is at right angles to the two lines GH and GI, which touch one another at G, it will also be perpendicular to the plane drawn through GH and GI.[Margin: a — 4.undecimi. (XI.4)] Hence, since AB and EF are parallel, and EF is perpendicular to the plane drawn through GH and GI, AB too will be perpendicular to the same

plane.[Margin: b — 8.undecimi. (XI.8)] Likewise, since CD and EF are parallel, and EF is perpendicular to the plane drawn through GH and GI, CD too will be perpendicular to the same plane.[Margin: c — 8.undecimi. (XI.8)] And accordingly, since the lines AB and CD are both perpendicular to the same plane drawn through GH and GI, they will be parallel.[Margin: d — 6.undecimi. (XI.6) [?] — printed digit smudged; the argument (two lines perpendicular to the same plane are parallel) requires XI.6] Therefore lines which are parallel to the same straight line, but not in the same plane with it, are also parallel to one another. Which was to be demonstrated.

Diagram. Three lines: two outer parallels and a central line, with two perpendiculars meeting at the central point in a bowtie configuration.

- A (upper left) — H (upper center-left) — B (upper right): the upper parallel AB, with H the foot of one perpendicular
- E (middle left) — G (middle center) — F (middle right): the central line EF, with G the chosen point
- C (lower left) — I (lower center-left) — D (lower right): the lower parallel CD, with I the foot of the other perpendicular
- The perpendiculars GH (rising to H) and GI (descending to I) cross the central line at G

SCHOLIUM. — Euclid deliberately required that the two lines AB and CD not lie in the same plane as the line EF to which they are parallel. For if they did lie in the same plane as EF, then AB and CD would be parallel to one another by I.30, and so it would be superfluous to prove the same thing here.

THEOR. 10. PROPOS. 10.

[Margin: x]

If two straight lines meeting one another are parallel, respectively, to two straight lines meeting one another but not in the same plane, they will contain equal angles.

Let the lines AB and AC, meeting at A, be parallel to the lines DE and DF [recte: DF; printed "EF"], which meet at D; and let AB and AC not lie in the same plane as DE and DF. I say that the angles BAC and EDF contained by them are equal. Set AB and DE equal to one another, and AC and DF equal to one another; and draw the lines BC, EF, BE, AD, and CF. Since, therefore, AB and DE are parallel and equal, BE and AD will also be parallel and equal.[Margin: a — 33.pri. (I.33)] By the same argument CF and AD will be parallel and equal. Therefore, since BE and CF are

both parallel and equal to the same line AD, BE and CF will also be parallel and equal to one another;[Margin: b — 9.undecimi. (XI.9)] and consequently the lines BC and EF will be parallel and equal.[Margin: c — 33.pri. (I.33)] Since, then, the sides AB and AC of triangle ABC are equal to the sides DE and DF of triangle DEF by construction, and the base BC is equal to the base EF, as we have just shown, the angles BAC and EDF contained by the said sides will be equal.[Margin: d — 8.pri. (I.8)] Therefore, if two straight lines meeting one another, and so on. Which was to be shown.

Diagram. An elongated triangular figure (an oblique prism) with a small triangle at the top and a small triangle at the bottom, joined by long edges.

- A (apex, top): vertex of the upper triangle
- B (upper left) and C (upper right): the base ends of the upper triangle ABC
- D (interior, lower middle): apex of the lower triangle
- E (bottom left) and F (bottom right): the base ends of the lower triangle DEF
- The connecting edges BE, CF, and AD run down the length of the figure

SCHOLIUM. — The conclusion of this theorem is also true when the two former lines lie in the same plane as the two latter. For let there be four lines AB, AC, DE, DF in the same plane, with AB parallel to DE and AC parallel to DF. I say that the angles BAC and EDF are equal. For set AB equal to DE, and AC equal to DF, and draw the lines BC [recte: BC; printed "EC"] and EF, which will either lie in one straight line or not. First let them lie in one straight line BF. Since, then, AB and DE are parallel, the angles ABC and DEF — the interior and the exterior — will be equal.[Margin: e — 29.pri. (I.29)] Likewise the angles ACB and DFE will be equal, since AC and DF are also parallel. Therefore the two angles ABC and ACB of triangle ABC are equal to the two angles DEF and DFE of triangle DEF. And so the remaining angles too, BAC and EDF, will be equal.[Margin: f — 32.pri. (I.32)] Which is what was proposed.

Diagram. Two triangles standing side by side on a single base line.

- A (apex, left): vertex of the left triangle
- B (bottom left) and C (bottom, center-left): base ends of the left triangle ABC
- D (apex, right): vertex of the right triangle
- E (bottom, center-right) and F (bottom right): base ends of the right triangle DEF
- The base ends lie collinearly as B–C–E–F

Now let BC and EF not lie in one straight line. Drawing the lines AD, BE, and CF: since AB and DE are parallel and equal, AD and BE too will be parallel and equal. [Margin: g — 33.pri. (I.33)] By the same reasoning AD and CF will be parallel and equal, because AC and DF are assumed parallel and equal. Therefore, since BE and CF are both parallel and equal to the same line AD, they will be parallel and equal to one another; [Margin: h — 30.pri. (I.30)] and accordingly BC and EF too will be parallel and equal. [Margin: i — 33.pri. (I.33)] And so, since the two sides AB and AC of triangle ABC are equal to the two sides DE and DF of triangle DEF, and the base BC is equal to the base EF, the angles BAC and EDF contained by the said sides will be equal. [Margin: k — 8.pri. (I.8)] Which is what was proposed.

Diagram. An oblique parallelepiped-like figure illustrating the case in which the two triangles are not coplanar.

- D (top): apex
- F (right): upper-right vertex
- E (interior center): a vertex within the figure
- A (left): left vertex
- B (bottom left): lower vertex
- C [?] (bottom right): lower vertex (label faint on the tile)

However, in order for the conclusion of this theorem to be rightly drawn from the given hypothesis, it is necessary that the parallel lines be so placed (whether they all lie in the same plane or not) that the three lines AD, BE, and CF in no way cut one another — as is clear from the first and last figures. For otherwise the conclusion will not be true.

For the lines AB and AC are parallel to the lines DE and DF in this figure; and yet the angles BAC and EDF which they contain are not equal, since the one is acute and the other obtuse. This happens because AD and CF cut one another. Hence, although AC and DF are parallel and equal, it does not follow that AD and CF, which join them, are parallel and equal, because they do not join them toward the same parts, as I.33 requires. Therefore the demonstration of this theorem does not hold when this condition is lacking — a condition which is nevertheless preserved in the earlier figures.

Diagram. The failing case, a slanted quadrilateral figure in which the joining lines cross.

- B (top left) and A (top right): the meeting point A of the upper pair of lines
- F (center): the crossing point of the joining lines

- C (right, below A): a vertex
- E (bottom left) and D (bottom center): the meeting point D of the lower pair of lines
- The joining lines AD and CF cross one another at F, so the angle BAC comes out acute while EDF is obtuse

PROBL. 1. PROPOS. 11.

[Margin: xj]

From a given point above a plane, to draw a straight line perpendicular to the plane below.

Let a perpendicular have to be drawn from the point A, above, to the plane BC lying below. In the plane BC draw any line DE, and from A drop the perpendicular AF onto it.[Margin: a — 12.pri. (I.12)] Then in the plane BC, through F, erect GH perpendicular to DE,[Margin: b — 11.pri. (I.11)] and from A drop the perpendicular AI onto it. I say that AI is perpendicular to the plane BC lying below. For draw in the plane BC, through I, the line KL parallel to DE; [Margin: c — 12.pri. (I.12)] since DE [recte: DE; printed "DF"] is at right angles to the two lines FA and FH by construction,[Margin: d — 31.pri. (I.31)] and consequently KL is a line perpendicular to the plane drawn through FA and FH, [Margin: e — 4.undecimi. (XI.4)] KI too will be a line perpendicular to that same plane drawn through FA and FH.[Margin: f — 1.undecimi. (XI.1)] But since AI lies in the same plane as the lines FA and FH, and touches the line KI at I, by definition 3 of this book the angle KIA will be right;[Margin: g — 12.undecimi. (XI.12) [?] — this back-reference is anomalous (XI.12 is the following proposition); transcribed as printed] and thus AI will be at right angles to the two lines KI and IF. Therefore AI will be perpendicular to the plane BC.[Margin: h — 4.undecimi. (XI.4)] And so from a given point above a plane we have drawn a straight line perpendicular to the plane below. Which was to be done.

Diagram. A rectangle representing the plane BC seen in perspective, with the point A raised above it and a web of construction lines within the plane.

- A (top, above the plane): the given point on high
- B and D (upper-left corner region): B leftmost, D just inside
- K (upper center): endpoint of the parallel KL
- H (upper right): endpoint of the erected perpendicular GH
- I (center): the foot of AI, where KL passes

- F (center-left, lower): the foot of AF on DE, and the point through which GH is erected
- G (bottom left): endpoint of GH
- E (bottom center): endpoint of DE
- C (bottom right corner of the plane)

The line DE runs across the plane, GH crosses it at F, KL passes through I, and AF, AI descend from A. (The endpoint L of KL is not distinctly labelled on the tile.)

SCHOLIUM. — But should it happen that the perpendicular AI, drawn to GH, falls upon the point F — so that it is the very same as the perpendicular AF drawn to DE — then AF itself, the perpendicular drawn from the outset to DE, will be perpendicular to the plane BC lying below, since it is perpendicular to both DE and GH.[Margin: i — 4.undecimi. (XI.4)]

PROBL. 2. PROPOS. 12.

[Margin: xij]

From a given point in a given plane, to erect a straight line at right angles to the plane.

Let a perpendicular to the given plane BC have to be drawn from the given point A in the plane BC. From any point D, above, drop the perpendicular DE to the plane BC.[Margin: a — 11.undecimi. (XI.11)] If it falls on the point A, what was proposed is done. But if it falls on another point E, then extend the line through E and A, and through A draw AF parallel to DE, in the plane GH drawn through DE and EA.[Margin: b — 31.pri. (I.31)] I say that AF is perpendicular to the given plane BC. For since DE and AF are parallel, and DE is perpendicular to the plane BC by construction, AF too will be perpendicular to the same plane BC.[Margin: c — 8.undecimi. (XI.8)] And so, from a given point in a given plane, and so on. Which was to be done.

Diagram. A parallelogram representing the plane, with an auxiliary plane GH standing on it and two perpendiculars.

- G (top left), F (top center), D (top right): the upper edge of the auxiliary plane GH
- B (below G): a vertex of the auxiliary plane
- A (lower center-left) and E (lower center): points in the base plane, A the given point and E the foot of DE
- H (right): a vertex of the auxiliary plane

- C (bottom right): corner of the base plane
- DE descends to E and AF rises from A, both perpendicular to the base plane

THEOR. 11. PROPOS. 13.

[Margin: xiiij] [*The heading is set in italic type: "THEOR. 11. PROPOS. 13."*]

From a given point in a given plane, two straight lines cannot be erected at right angles to the plane on the same side.

Let AB be the given plane. I say that from its given point C, two perpendiculars to the plane AB cannot be drawn toward the same parts. For if it can be done, let two perpendiculars CD and CE be drawn to the plane AB; and through CD and CE, which lie in one and the same plane, let a plane FG be drawn, cutting the plane AB along the straight line GH.[Margin: a — 2.undecimi. (XI.2)] Since, then, EC and DC are at right angles to the plane AB, by definition 3 of this book the angles ECG and DCG will be right, and accordingly equal — a part equal to the whole. This is absurd. Therefore, from a given point in a given plane, two straight lines cannot be erected at right angles to the plane on the same side. Which was to be demonstrated.

ALTERNATIVELY. From C, if it can be done, draw two perpendiculars CD and CE to the plane AB. Then, since the two lines DC and EC are at right angles to the same plane AB, they will be parallel to one another[Margin: b — 6.undecimi. (XI.6)] — and yet they meet at the point C. This is absurd.

Diagram. A parallelogram representing the plane AB, with the cutting plane FG and two perpendiculars rising from C.

- F (top left), D (top center), E (top right): the upper edge, with D and E the tops of the two perpendiculars
- A (interior, upper left): a point in the plane
- H (left corner): endpoint of the section GH
- C (bottom center): the given point in the plane
- G (right): the other endpoint of the section GH
- B (bottom): corner of the plane
- The perpendiculars CD and CE rise from C, and the cutting plane FG meets the base plane along GH

SCHOLIUM. — In the same way, from a point above a plane, two straight lines cannot be dropped perpendicular to the plane below. For let there be drawn...

Euclid, *Elements*, Book XI (continued)

Commentary of Christoph Clavius. Enunciations of Euclid are set as block quotations; Clavius's demonstrations and scholia follow as ordinary prose. Superscript letters mark the citation-letters carried in the printed margin.

Scholium to Proposition 13 (concluded)

[Margin: xiiij.]

(continued from the previous page) For suppose that from A, a point raised above the underlying plane BC, two perpendiculars AD, AE could — if it were possible — be dropped to it. Through AD and AE, which lie in one plane, let a plane FG be drawn,^c cutting the plane BC along the straight line GH. [Margin: c — Elements XI.2] Since AD and AE are perpendicular to the plane BC, then by definition 3 of this book the two angles ADE and AED will be interior right angles in the triangle ADE — which is absurd,^d since any two angles taken in any triangle whatever are together less than two right angles. [Margin: d — Elements I.17]

Otherwise: if AD and AE are perpendicular to the plane BC, then they will be parallel to one another,^e and yet they meet at the point A. Which is absurd. [Margin: e — Elements XI.6]

Diagram. The plane BC is drawn as a foreshortened parallelogram lying below; the point A stands raised above it. Two perpendiculars AD, AE fall from A to the base, and the auxiliary plane FG (with F at the upper left) passes through them, cutting BC along the line GH.

- A (raised apex): the elevated point
- F (upper left): far corner of the cutting plane FG
- B (upper left edge): corner of plane BC
- H (base, left): one end of the common section GH
- D, E (base, center): feet of the two perpendiculars
- G (base, right): other end of the common section GH
- *(lower corner of plane BC, unlabeled / illegible) [?]*

THEOR. 12. PROPOS. 14.

[Margin: xiiij.]

Planes to which the same straight line is perpendicular are parallel.

Let the straight line AB be perpendicular to the planes CD and EF. I say that the planes CD and EF are parallel. For if they be not believed to be parallel, then when produced they will meet one another. Let them meet toward the parts C, E, and let them form as common section the straight line GH.^a [Margin: a — Elements XI.3] Take on it any point I whatever, and draw the straight lines IA, IB in the planes GCD, GEF. Now since AB is set perpendicular to the planes GCD, GEF, then by definition 3 of this book the two angles IAB, IBA will be right angles in the triangle ABI.^b But they are also less than two right angles — which is absurd. [Margin: b — Elements I.17] Therefore the planes CD, EF, however far produced, never meet one another; and so they are parallel. Therefore, planes to which the same straight line is perpendicular, and so forth. Which was to be demonstrated.

Diagram. A tent-shaped figure: from the apex G two sloping planes GCD and GEF descend to the base, with the perpendicular AB set up through the interior. The point I lies on the supposed common section, and the auxiliary lines IA, IB form the triangle ABI.

- G (apex): meeting point of the two planes
- I (just below G): point taken on the common section
- C (left), E (right): base ends of the two planes
- H (center): on the base
- A, B (lower center): foot points of the perpendicular AB / triangle ABI
- D (lower left), F (lower center): base corners

Scholium

It will also be easy to demonstrate the converse of this, namely:

If there be two parallel planes, a straight line which is perpendicular to one of them will be perpendicular to the other as well.

Let there be two parallel planes AB, CD, to one of which, AB, let the straight line EF be perpendicular. I say that EF is perpendicular to the remaining plane CD as well. For let some plane, namely GK, cut the planes AB, CD, passing along the straight line EF, and let it make with those planes the common sections — the straight lines GH, IK. Then by definition 3 of this book the angles GEF, HEF will be right angles; and consequently the angles IFE, KFE will be right angles too. (For if one of them, say IFE, were said to be acute, the two angles GEF, IFE would be less than two right angles. Then the straight lines EG, FI, toward the parts G, I, would meet in the plane GK — namely at a point L; and so the planes AB, CD, in which they lie, would likewise meet toward the same parts at the point L,^c [Margin: c —

Elements XI.1] since the whole straight line HGL lies in one plane, namely in AB produced, and likewise the whole straight line KIL lies in one plane, namely in CD produced. Which is absurd, since they are supposed parallel. Therefore the angles IFE, KFE are right angles.) In the same way, if another plane, namely MN, cut the same planes along EF, making with those sections the other common straight lines MO, PN, the angles PFE, NFE will be right angles.^d [Margin: d — Elements XI.4] And so, since EF is perpendicular to the two straight lines IK, PN, it will also be perpendicular to the plane CD, drawn through them. Which was proposed.

Diagram. A prism-like construction: the two parallel planes AB (lower) and CD, together with the cutting planes GK and MN, all threaded by the perpendicular line EF. The common sections GH, IK, MO, PN are drawn as parallel edges.

- G, L, I (upper edge): tops of the cutting plane GK / point L where the produced lines would meet
- M (left), C (upper center): further plane corners
- A, P (center): interior points
- E, F (center): endpoints of the perpendicular EF
- N (right): section endpoint
- B, H, O, K, D (base): base corners and section feet

Since EF is thus perpendicular to the two straight lines IK, PN, it will likewise be perpendicular to the plane CD drawn through them. Which was proposed.

THEOR. 13. PROPOS. 15.

[Margin: xv.]

If two straight lines meeting one another are parallel to two straight lines meeting one another that are not situated in the same plane, then the planes drawn through them are parallel.

Let there be two straight lines AB, AC meeting one another at A, parallel to two straight lines DE, DF meeting one another at D and lying in another plane together with them. I say that the planes BC, EF drawn through them are parallel too. For from A^a let there be dropped to the plane EF the perpendicular AG, meeting the plane EF at the point G. [Margin: a — Elements XI.11] Then in the plane EF, through G, let GH, GI be drawn parallel to DE, DF respectively.^b [Margin: b — Elements I.31] Now since the straight lines AB, GH are parallel to DE,^c then AB and GH will also be parallel to one another; [Margin: c — Elements XI.9] and consequently the angles BAG, AGH are together equal to two right angles.^d

[Margin: d — Elements I.29] But AGH is a right angle, by definition 3 of this book; therefore the angle BAG will be a right angle too. By a like argument you will conclude that the angle CAG is a right angle. And so, since the straight line GA is perpendicular to the two straight lines AB, AC, it will also be perpendicular to the plane BC drawn through them.^e [Margin: e — Elements XI.4] But it is also perpendicular to the plane EF, by construction. Therefore the planes BC, EF are parallel.^f [Margin: f — Elements XI.14] So if two straight lines meeting one another, and so forth. Which was to be demonstrated.

Diagram. Two planes are shown edge-on and parallel: the plane BC (with A the vertex of the angle BAC and B, C its arms) and the plane EF (with D the vertex of the angle EDF and E, F its arms). The perpendicular AG falls from A onto EF at G, and GH, GI are drawn there parallel to DE, DF.

- D (top): vertex in plane EF
- F (right), G (center), I (right): endpoints / foot of perpendicular
- A (center left), C (below A): vertex and arm in plane BC
- B (lower left): arm of plane BC
- E, H (lower center): endpoints in plane EF

Scholium

But if the perpendicular drawn from A to the plane EF should fall on the point D itself, the same conclusion will be reached, with this exception, that

(catchword: quod)

[Margin: xv.]

(top of p. 503, running header "LIBER XI.") that in the plane EF no other parallels are to be drawn. Thus, if the lines GH, GI be set parallel to the straight lines AB, AC, in such a way that AG — the perpendicular to the plane HI drawn through GH, GI — falls on G, we shall show, as before, that GA is perpendicular to the plane BC drawn through the straight lines AB, AC, and so forth.

[Problem — to draw a plane parallel to a given plane]

From this theorem the following problem will be no difficulty; namely:

Given a plane, to draw through a given point that is not in it a plane parallel to it.

Let the given plane be AB, and let the point outside it be C, through which a plane is to be drawn parallel to the plane AB. In the plane AB let two straight lines DB, DA be drawn arbitrarily, meeting one another at the point D, from which let the straight line DC be drawn to C. Then in the plane BC, drawn through the straight lines DB, DC, let CE be drawn parallel to DB;^f [Margin: f — Elements I.31] and in the plane AC, drawn through the straight lines DA, DC, let CF likewise be made parallel to DA. I say that the plane EF, drawn through the straight lines CE, CF, is parallel to the given plane AB. For since the two straight lines DB, DA, meeting one another at D, are parallel to the two straight lines CE, CF, which meet one another at C and lie in another plane together with them, the planes AB, EF drawn through them will be parallel.^g [Margin: g — Elements XI.15] Which was proposed.

Diagram. A cube-like parallelepiped showing the given plane AB and the constructed parallel plane EF. The line DC joins the plane AB (through D) to the external point C.

- D (top left), C (top right): D in plane AB, C the external point
- A (center left), F (right): interior/upper corners
- B (lower left), E (lower center): base corners

THEOR. 14. PROPOS. 16.

[Margin: xvj.]

If two parallel planes are cut by any plane, their common sections are parallel.

Let the parallel planes AB, CD be cut by the plane EF along the straight lines EH, GF. I say that their common sections EH, GF are parallel lines. For if they be not parallel, then when produced they will meet one another, since they lie in the cutting plane EF. Let them therefore meet at the point I.^a [Margin: a — Elements XI.1] Then since the whole straight line HEI lies in one plane, namely in AB produced, and likewise the whole straight line FGI lies in one plane, namely in CD produced, the planes AB, CD, produced, would also meet at I — which is absurd, since they are supposed parallel. Therefore the straight lines EH, GF are parallel. So if two parallel planes be cut by any plane, and so forth. Which was to be demonstrated.

Diagram. A tent-shaped figure: the two parallel planes AB and CD are cut by the plane EF, whose common sections EH, GF are drawn as edges; produced, they would meet at the apex I.

- I (apex): point where the produced sections would meet
- A (left), E, G (upper center) [?], C (right) [?]: upper corners / section points
- B, H, F, D (base): base corners and section feet

Scholium

This theorem can in no way be converted. For although the common sections of parallel planes, made by another cutting plane, are parallel — as has here been demonstrated — nevertheless not all those planes whose common sections made by another cutting plane are parallel are themselves parallel; for through two parallel straight lines infinitely many planes can be drawn, of which only two are parallel, while the others, produced in some direction, meet.

Moreover, from this theorem we gather another, similar to theorem 30 of Book 1:

Planes parallel to the same plane are also parallel to one another.

Let there be two planes AB, CD parallel to the plane EF. I say that AB and CD are parallel too. For let all three planes be cut by the plane GH, and let their common sections be the straight lines GI, KL, MH. Let them again be cut by another plane NH, and let their common sections be the straight lines NI, OL, PH — yet on this condition, that the two cutting planes GH, NH also cut one another, their common section being the straight line HI. Now since the parallel planes AB, EF are cut by the plane GH, the common sections GI, KL will be parallel.^b [Margin: b — Elements XI.16] In the same way MH, KL will be parallel,^c and so GI, MH will be parallel to one another. [Margin: c — Elements XI.9] We shall show in no other way that NI, PH are parallel. And so, since IG, IN, meeting one another at I, are parallel to the straight lines HM, HP, which meet at H and lie in another plane, the planes AB, CD drawn through them will be parallel.^d [Margin: d — Elements XI.15 (*leading digit foxed; read as "15.undecimi"*)] Which was proposed.

Otherwise: In the third plane EF take any point G whatever, from which, on either side, let a straight line be produced perpendicular to the plane EF, meeting the plane AB at the point H and the plane CD at the point I. Now since the line HG is perpendicular to the plane EF, it will also be perpendicular to the plane AB, which is parallel to it, by what we demonstrated in the scholium to proposition 14 of this book. By the same reasoning GI will be perpendicular to the plane CD. Therefore, since the straight line HI is perpendicular to the planes AB, CD, the planes AB, CD will be parallel to one another.^e [Margin: e — Elements XI.14] Which was proposed.

Diagram. Three parallel planes drawn edge-on and slanted (AB, EF, CD), cut by the two planes GH and NH, whose common sections GI, KL, MH and NI, OL, PH are drawn as crossing diagonals. The cutting planes meet along HI.

- A, G (upper left), E (upper center), C (upper right): upper corners
- N (left), I, L, M (center), H (right): section points / meeting points
- B (lower left), O, F, P (center), D (lower right): base points

Diagram. For the "otherwise" argument: three parallel planes shown as upright rectangles (AB, EF, CD), threaded by the perpendicular HI which passes through the point G, meeting the planes at H, G, I.

- A, E, C (top): upper corners of the three planes
- H, G, I (middle): feet of the perpendicular in each plane
- B, F, D (bottom): base corners

But if two planes are parallel to another plane, yet not to one another but meet — then they form one plane; just as two straight lines parallel to another straight line, if they meet, constitute one straight line, as we demonstrated at proposition 30 of Book 1. For let the planes AB, CD be parallel to the plane EF, and let them, produced, meet along the straight line CG. I say that the planes AB, CD constitute one plane. For let some plane HI cut all three planes along the straight lines HK, LM, MI. Now since the planes AB, EF are parallel, the common sections LM, HK will be parallel too.^f [Margin: f — Elements XI.16] By the same reasoning IM, HK will be parallel. Therefore, since the straight lines LM, IM are parallel to HK, and lie in the same cutting plane HI, and meet at M, they are set in a straight line and continuous, by what we showed at proposition 30 of Book 1. And so the planes AB, CD will form one plane;^g [Margin: g — Elements XI.1] namely because the straight line LI lies in one plane. Which was proposed.

Diagram. A cube-like figure showing the two planes AB, CD meeting along CG, both parallel to EF, cut by the plane HI along HK, LM, MI.

- H, F (top left), L, A (top): upper corners
- C (right), M (center), B (center) [?]: interior/side points
- G (center), K, D, I (base): base corners

(catchword: ITAQVE)

(top of p. 504, running header "EVCLID. GEOM.")

Therefore two planes which are parallel to another plane will either be parallel to one another, or — if, being produced, they meet — will certainly form one plane.

Moreover, here too we shall easily demonstrate the converse of proposition 10, namely:

If in parallel planes two angles are equal, and one line of the one angle is parallel to one line of the other angle, then the other line will also be parallel to the other line — provided only that they be drawn from the same side of the planes drawn through the former parallels.

For in parallel planes let the angles BAC, EDF be equal, and let AB be parallel to DE, and let AC, DF be drawn toward the same parts of the plane drawn through AB, DE. I say that AC, DF are parallel too — that is, that when the straight line AD is drawn, the plane drawn through AC, AD passes also through the straight line DF, so that AC, DF are the common sections made by the plane drawn through AC, AD in the parallel planes drawn through AB, AC and DE, DF. For from this^h it follows that the sections AC, DF are parallel. [Margin: h — Elements XI.16] Which was proposed. For if the plane drawn through AC, AD does not make in those parallel planes the sections AC, DF, let it make the sections AC, DG,ⁱ which will be parallel. [Margin: i — Elements XI.16] Then the angle EDG^k will be equal to the angle BAC, that is, to the angle EDF. [Margin: k — Elements XI.10] Which is absurd, since the one is a whole and the other a part.

Diagram. An arrow-like figure spanning two parallel planes (drawn faintly as parallelograms): at the top the angle BAC (vertex A, arms to B and C); the line AD descends to D in the lower plane, where the angle EDF (arms to E and F) opens, with the auxiliary arm DG alongside DF.

- A (top): vertex of the upper angle
- B (left), C (right): arms of the upper angle
- D (center): vertex of the lower angle
- E (lower left), F (lower center): arms of the lower angle
- G (lower center, beside F): auxiliary point

THEOR. 15. PROPOS. 17.

[Margin: xvij.]

If two straight lines are cut by parallel planes, they will be cut in the same ratios.

Let the straight lines AB, CD (whether they be parallel, as in the figure, or not, yet lying in the same plane; or set transversely, lying in different planes) be cut by the parallel planes EF, GH, IK at the points L, M, N, O, P, Q. I say that they are cut

proportionally — that is, that their segments intercepted between the said planes are proportional, so that as LM is to MN, so is OP to PQ. For let the straight lines LO, NQ be drawn in the planes EF, IK, and let the straight line LQ be joined, meeting the plane GH at the point R, from which let the straight lines RM, RP be drawn to the points M, P in the same plane GH. Then the triangle LNQ will lie in one plane,^a and likewise the triangle LOQ in one plane. [Margin: a — Elements XI.2] Now since the parallel planes GH, IK are cut by the plane of the triangle LNQ, their common sections MR, NQ will be parallel;^b and by the same reasoning RP, LO will be parallel. [Margin: b — Elements XI.16] Wherefore, as LR is to RQ, so is LM to MN;^c and likewise, as LR is to RQ, so is OP to PQ; and consequently, as LM is to MN, so is OP to PQ. [Margin: c — Elements VI.2] So if two straight lines be cut by parallel planes, and so forth. Which was to be demonstrated.

Diagram. Three parallel planes drawn as upright slanted strips (EF, GH, IK, with E,G,I along the top and F,H,K along the bottom). The straight line AB crosses the tops through L, M, N; the straight line CD crosses the bottoms through O, P, Q; the diagonal LQ passes through R in the middle plane.

- A (top left), E, L (upper left strip): line AB entering / section points
- G, M (upper center): middle strip
- I, N, B (upper right): right strip / line AB exit
- C, O, F (lower left): line CD entering / feet
- P, H (lower center): middle strip foot
- Q, K, D (lower right): right strip / line CD exit
- R (center): point where LQ meets the middle plane GH

Scholium

If the given straight lines AB, CD lie in one and the same plane, the two straight lines RM, RP will form one straight line, as appears in the figure above. For then the plane drawn through the straight lines AB, CD will cut the three parallel planes at the points L, O, M, P, N, Q, and along the straight lines LO, MP, NQ,^d which will be parallel to one another; and the point R will lie on the straight line MP, since it lies both in the plane drawn through the straight lines AB, CD (because the points L, Q lie in that same plane, as we said in the scholium to proposition 7 of this book) and in the plane GH, and so on MP, the common section of those planes. [Margin: d — Elements XI.16] Therefore RM, RP will constitute one straight line MP, namely the common section of the planes LO, QN, GH.

But if the two straight lines AB, CD do not lie in the same plane, then RM, RP will not form one straight line, as appears in these two figures. For since the triangle LOQ lies in one plane,^e and the triangle LNQ in another plane distinct from it, [Margin: e — Elements XI.2] (for if those two triangles lay in one and the same plane, the two straight lines AB, CD would lie in that same plane, which is constituted from them — which is contrary to the hypothesis), the straight lines RM, RP will lie in those distinct planes of the triangles, and consequently will not constitute one straight line;^f otherwise they would lie in one plane. [Margin: f — Elements XI.1] Which is absurd.

This same proposition also holds if the two straight lines AB, CD, though lying in the same plane, are not parallel, as appears in these same two figures; but then MRP will always be one straight line, as was demonstrated at the beginning of this scholium when AB, CD were placed in one plane. For the same demonstration can be applied here.

Likewise, if more than three parallel planes cut the straight lines AB, CD, their parts will be proportional, and the common sections

(catchword: sectio-)

Diagram. A second figure like the last: three parallel slanted planes (E,G,I above; F,H,K below) with the transversals AB and CD and the diagonal through R and M, P.

- E, G, I (top): tops of the three planes
- A, L, M, N, B (upper transversal AB): line and section points
- R (center), M, P: diagonal / section points
- C, O, P, Q, D (lower transversal CD): line and section points
- F, H, K (bottom): feet of the three planes

Diagram. The case in which AB, CD do not lie in one plane: the two transversals cross, so that the triangles LOQ and LNQ lie in different planes. Points R, M lie at the crossing.

- A (upper left), E, L, G, R, Q [?], D (upper region): line AB and section points, with D at upper right
- C, O, F (left): line CD entering
- M, R (center): crossing points
- N, H, K (lower center/right), B (lower right): section points and line AB exit

the sections made by the intermediate planes, and by the triangles LOQ and LNQ, will constitute straight lines — provided the lines AB and CD lie in one plane; but they will not be straight lines if AB and CD do not lie in one plane, just as was said of the straight lines MR and RP.

Moreover, it is clear from the demonstration that if any number of lines lying in one plane are cut by any number of parallel lines, the segments of those lines lying between the parallels are proportional. For let AB and CD be two straight lines, arranged in any manner in one plane, as in the last figure, and let them be cut by three parallels LO, RPM (for the letter P now refers to the intersection of the lines CD and RM) and QN. I say that the segments LM and MN have the same ratio as the segments OP and PQ. For, when the straight line LQ has been joined, [Margin: a — Elem. VI.2] then, on account of triangle LOQ, LR is to RQ as OP is to PQ; and on account of triangle LNQ, LR is to RQ as LM is to MN. Therefore OP will be to PQ as LM is to MN. And the same reasoning holds for more lines. But in order that the demonstration may proceed correctly with any two lines whatever, a straight line must be drawn from the first point of section of the one line to the last point of section of the other. So you see that in the two lines AB and CD a straight line has been drawn from L, the first point of the line AB, to Q, the last point of the line CD. And the same procedure has been kept in the figures of this Proposition 17.

THEOR. 16. PROPOS. 18.

[Margin: xviii]

If a straight line is at right angles to any plane, then all planes drawn through it will also be at right angles to that same plane.

Let AB be at right angles to the plane CD. I say that all planes drawn through the line AB are at right angles to that same plane CD. For let a plane EF be drawn through AB, cutting the plane CD along the straight line FG. Then take a point H anywhere on the line FG, and [Margin: a — Elem. I.31] in the plane EF draw HI parallel to AB. Now since AB and IH are parallel, and AB is set at right angles to the plane CD, [Margin: b — Elem. XI.8] IH too will be at right angles to that same plane CD; and therefore, by Definition 3 of this book, it is perpendicular to the common section FG. By the same reasoning all the lines that are drawn in the plane EF parallel to AB will be at right angles to the plane CD, and therefore, by Definition 3 of this book, perpendicular to the common section FG. Hence the plane EF is at right angles to the plane CD, by Definition 4 of this book. And by a similar argument all the other planes drawn through the line AB will be shown to

be at right angles to the plane CD. Therefore, if a straight line is at right angles to any plane, and so on. Which was to be demonstrated.

Diagram. The figure for Proposition 18. A horizontal plane CD is drawn as a leaning parallelogram; a second plane EF stands on it, meeting it along the line FG. The line AB rises from the base to the plane, with HI drawn parallel to it. Readable labelled points:

- C (upper left of the standing plane)
- I, A, E (across the top edge)
- F, H, B, G (along the base line, left to right)
- D (lower right corner of the horizontal plane)

SCHOLIUM.

From these results this further theorem may be demonstrated, namely:

Two planes at right angles to the same plane, in which they make parallel common sections, are parallel to each other; and of two parallel planes, if one is at right angles to any plane, the other will also be at right angles to that same plane.

Let the planes AB and CD be at right angles to the plane EF, making the parallel sections GH and IK. I say that they are parallel. For in the plane EF draw LM perpendicular to GH, which, by Definition 4 of this book, will be at right angles to the plane AB. [Margin: c — Elem. I.29] And the same perpendicular will be at right angles to IK; and therefore, by Definition 4 of this book, it will also be at right angles to the plane CD. Since, then, LM is at right angles to both planes AB and CD, [Margin: d — Elem. XI.14] they will be parallel.

But now let the planes AB and CD be parallel, and let AB be at right angles to the plane EF. I say that CD is also at right angles to that same plane EF. For let the common sections of the plane EF with the planes AB and CD be the straight lines GH and IK, [Margin: e — Elem. XI.16] which will be parallel. When the line LM has also been drawn in the plane EF perpendicular to the line GH, this, by Definition 4 of this book, will be at right angles to the plane AB. Therefore, by the scholium to Proposition 14 of this book, the same LM will also be at right angles to the plane CD. [Margin: f — Elem. XI.18] Hence the plane EF, drawn through the line LM, will be at right angles to the plane CD; and consequently, in turn, the plane CD will also be at right angles to the plane EF. Which is what was proposed.

Diagram. The scholium figure. Two upright planes AB and CD stand on a horizontal plane EF, meeting it along the parallel sections GH and IK; the line LM lies in EF perpendicular to both. Readable labelled points:

- E, G, I (across the top)
- A (left plane, upper), C (right plane, upper)
- L, M (interior, on the line LM)
- B (left plane, lower)
- H, D (lower interior)
- K, F (along the base)

From this, the following problem too will be solved:

Through a straight line given in any plane, to draw a plane at right angles to that plane.

Let FG be a straight line given in the plane CD, as in the figure of this Proposition, and let it be required to draw through FG a plane at right angles to the plane CD. From any point B of the line FG [Margin: g — Elem. XI.12] erect BA perpendicular to the plane CD, and through the lines AB and FG let the plane EF be drawn, [Margin: h — Elem. XI.18] which will be at right angles to the plane CD. Which is what was proposed.

THEOR. 17. PROPOS. 19.

[Margin: xix]

If two mutually intersecting planes are at right angles to a given plane, their common section will also be at right angles to that same plane.

Let two planes AB and CD, mutually intersecting along the straight line EF, be at right angles to the plane GH. I say that their common section EF is also at right angles to that same plane GH. For either EF is at right angles to BF and DF, the common sections of the planes AB and CD with the plane GH, or it is not. If EF is at right angles to BF and DF, [Margin: a — Elem. XI.4] it will also be at right angles to the plane GH, which is drawn through them. But if EF be granted to be at right angles to only one of the lines BF and DF, let it be at right angles to BF. Now since the plane AB is set at right angles to the plane GH, then EF — which in the plane AB is drawn perpendicular to BF, its common section with the plane GH — will be at right angles to the plane GH, by Definition 4 of this

Diagram. The figure for Proposition 19. A horizontal plane GH is shown as a leaning parallelogram; two planes AB and CD stand upon it and cross along the vertical line EF, which meets the base at F. Readable labelled points:

- C (top, apex of the standing intersection)
- A, E (upper middle)
- G (left corner of the horizontal plane)
- K, I (interior, near the crossing)
- F (interior foot of EF)
- B (right corner)
- D, H (along the lower edge)

book. The same conclusion follows if EF be granted to be at right angles to DF; for then too EF will be at right angles to the plane GH, by Definition 4 of this book, since it is set perpendicular to DF, the common section of the plane CD with the plane GH, and is drawn in the plane CD, which is at right angles to the plane GH. Finally, if EF be believed to be at right angles to neither BF nor DF, [Margin: b — Elem. I.11] let there be drawn from F, in the plane AB, perpendicular to BF (its common section with the plane GH), the line FI; and likewise in the plane CD, perpendicular to DF (its common section with the plane GH), the line FK. Now since the plane AB is set at right angles to the plane GH, the perpendicular IF — which is drawn in the plane AB to BF, its common section with the plane GH — will also be at right angles to the plane GH, by Definition 4 of this book. By the same reasoning KF will be at right angles to that same plane GH. And therefore two perpendiculars would have been raised from the point F to the plane GH. But this was shown above to be impossible. [Margin: c — Elem. XI.13] Hence EF will be at right angles to the plane GH. Therefore, if two mutually intersecting planes are at right angles to a given plane, and so on. Which was to be demonstrated.

Diagram. The figure for Proposition 19, repeated at the head of this page. It shows the same construction as fig-p505-3: horizontal plane GH with two crossing planes AB and CD meeting along EF. Readable labelled points:

- top apex label reads "G" [?] here (it reads "C" in the corresponding figure on p. 505 — likely a compositor variant or foxing)
- A, E (upper middle)
- G (left corner)
- K, I (interior, near the crossing)
- F (interior foot)
- B (right corner)

- D, H (lower edge)

THEOR. 18. PROPOS. 20.

[Margin: xx]

If a solid angle is contained by three plane angles, then any two of them, however chosen, are greater than the third.

Let a solid angle at A be contained by the three plane angles BAC, CAD, DAB. I say that any two of them are greater than the remaining one. For if all three are equal, it is evident that any two are greater than the remaining one. And if only two are equal, and the third is smaller than either, it is likewise established that any two are greater than the remaining one. But if one of them — say BAC — is the greatest, while the others are either equal or unequal, it is also manifest that each of these, together with that greatest one BAC, is greater than the remaining one. I now say that this greatest angle BAC is exceeded by the two angles BAD and DAC together. For in the plane through AB and AC [Margin: a — Elem. I.23] let the angle BAE be made equal to the angle BAD, and let the straight line AE be made equal to the straight line AD. Then, in the same plane, extend through E the straight line BC, cutting the lines AB and AC at B and C, and let the straight lines BD and DC be joined. Now since the sides AD and AB of triangle BAD are equal to the sides AE and AB of triangle BAE, and the angles contained by them are equal by construction, [Margin: b — Elem. I.4] the bases BD and BE will be equal. [Margin: c — Elem. I.20] But since the sides DB and DC are greater than the side BC, if the equal lines BD and BE are subtracted, the remaining line CD will be greater than CE. Since, then, the sides AD and AC of triangle DAC are equal to the sides AE and AC of triangle EAC, and the base CD is greater than the base CE, [Margin: d — Elem. I.25] the angle CAD will be greater than the angle CAE. Therefore, when the equal angles BAD and BAE are added, the two angles CAD and BAD will be greater than the two angles CAE and BAE — that is, greater than the whole angle BAC, which was posited to be the greatest of all. And consequently any two are much greater than the remaining one that is not the greatest. Therefore, if a solid angle is contained by three plane angles, and so on. Which was to be shown.

Diagram. The figure for Proposition 20. From a vertex A radiate lines to a base line BC; D stands above, with lines AD, DB, DC drawn, and E lies on BC between B and C. Readable labelled points:

- D (apex, top)
- A (interior, below D)

- B (base, left)
- E (base, middle)
- C (base, right)

THEOR. 19. PROPOS. 21.

[Margin: xxj]

Every solid angle is contained by plane angles that are less than four right angles.

Let the solid angle A be contained by the three plane angles BAC, CAD, DAB. I say that these three angles are less than four right angles. For when the straight lines BC, CD, DB have been drawn, there will be constituted three solid angles at B, C, D, each of which is contained by three plane angles: namely B, by CBA, ABD, DBC; C, by BCA, ACD, DCB; and D, by CDA, ADB, BDC. [Margin: a — Elem. XI.20] Now since the two angles CBA, ABD are greater than the angle CBD, and likewise the two angles BCA, ACD are greater than the angle BCD, and the two angles CDA, ADB are greater than the angle CDB, the six angles CBA, ABD, BCA, ACD, CDA, ADB will be greater than the three angles CBD, BCD, CDB. [Margin: b — Elem. I.32] But these three are equal to two right angles. Therefore those six will be greater than two right angles. Since, then, those six, together with the three at A, are equal to six right angles — on account of the three triangles BAC, CAD, DAB [Margin: c — Elem. I.32] (for the angles of any triangle are equal to two right angles) — if those six, which are greater than two right angles, are taken away, there will be left the three at A, constituting the solid angle, which are less than four right angles. Therefore every solid angle, and so on. Which was to be demonstrated.

Diagram. The figure for Proposition 21. A triangle DBC with apex D above the base BC, and an interior point A joined to the three vertices, forming the base triangle of a solid angle. Readable labelled points:

- D (apex, top)
- A (interior)
- B (base, left)
- C (base, right)

SCHOLIVM.

Since this demonstration is adapted by the commentators only to that solid angle which three plane angles constitute, we shall accordingly extend it to all solid angles in the following way.

Let there be any solid angle whatever, contained by any number of plane angles. I say that all of them together are likewise less than four right angles. For if straight lines are drawn to subtend all the plane angles in order, lying in the same plane, a pyramid will be constituted whose apex is the given solid angle, having as many sides — and as many angles — as there are plane angles by which the solid angle is comprehended; and therefore just as many triangles will surround the pyramid. Hence all the angles of these triangles

Diagram. Three schematic base-polygons illustrating the scholium, each divided into triangles from a central point: a hexagon partitioned into six triangles, a pentagon into five, and a quadrilateral (square) into four (drawn with both diagonals). The figures are unlettered.

Diagram. The same three schematic base-polygons repeated at the head of this page : a hexagon divided into six triangles, a pentagon into five, and a square into four (with both diagonals drawn). The figures are unlettered.

(the angles of the triangles), [Margin: d — Elem. I.32] since the angles of any triangle are equal to two right angles, will be equal to twice as many right angles as the base contains angles. But all the angles of the base are also equal to that same number of right angles less four, by what we demonstrated from Proclus in connection with Proposition 32 of Book 1. Therefore all the angles of the said triangles will exceed all the angles of the base by four right angles. Hence, since [Margin: e — Elem. XI.20] all the angles of these triangles near the base are greater than the angles of the base — because near the base solid angles are constituted, each of which is contained by three plane angles, and of these any two are greater than the remaining one, namely the one that lies in the base — all the angles of these triangles will exceed those same angles near the base by less than four right angles. Therefore, since all the angles of all the triangles exceed those same ones near the base (which constitute the solid angle) by less than four right angles, the angles which compose the solid angle will be less than four right angles. Which is what was proposed.

But that the matter may be better grasped, let there be, for the sake of example, a solid angle A contained by the five plane angles BAC, CAD, DAE, EAF, FAB, which are subtended in order by the straight lines BC, CD, DE, EF, FB, lying in one and the same plane — namely in that plane which cuts the lines AB, AC, AD, AE, AF at the points B, C, D, E, F; so that a pentagonal pyramid is constituted, having a pentagonal base and, around its sides, five triangles — as many, that is, as there are plane angles composing the solid angle A. [Margin: f — Elem. I.32] Now since all the angles of the five triangles BAC, CAD, DAE, EAF, FAB are equal to ten right

angles, while the five angles of the base BCDEF are equal to six right angles — that is, ten less four — the angles of the triangles will exceed the angles of the base by four right angles. Since, then, the ten angles of the triangles near the base are greater than the angles of the base — for since the solid angle B is contained by the three plane angles ABC, ABF, CBF, [Margin: g — Elem. XI.20] the two angles CBA, ABF, which are in the triangles, will be greater than the angle CBF, which is in the base; and by the same reasoning the remaining angles of the triangles near the base will be greater than the remaining angles in the base — the angles of the triangles adjacent to the base will be greater than six right angles. Therefore the remaining five, which constitute the solid angle A, will be less than four right angles, seeing that these together with those are equal to ten right angles, as has been said. The same demonstration is to be applied in all other solid angles.

Diagram. The worked example for the scholium to Proposition 21. A pentagon BCDEF with a central point A joined by straight lines to all five vertices, so as to form five triangles surrounding the vertex A of the pentagonal pyramid.

THEOR. 20. PROPOS. 22.

[Margin: xxij]

If there be three plane angles, any two of which, taken at will, are greater than the remaining one, and equal straight lines subtend them, then it is possible for a triangle to be constituted from the lines that join those equal straight lines.

Let there be three plane angles A, B, C, contained by the equal straight lines AD, AE, BF, BG, CH, CI, yet under this law: that any two of the angles are greater than the remaining one. I say that from the three straight lines DE, FG, HI — which join those equal straight lines — a triangle can be constituted; that is, that of the three lines DE, FG, HI any two are greater than the remaining one. For this being granted, [Margin: a — Elem. I.22] a triangle will easily be constructed from them. That the two lines DE, FG are greater than HI will be shown as follows. [Margin: b — Elem. I.23] Let the angle DAK be made equal to the angle B, and let AK first fall on the side of AD, so that a certain whole angle EAK is formed, composed of the

two angles EAD and DAK; this indeed will happen when the two angles DAE and B are less than two right angles. Let AK be set equal to AD, and let the straight lines KD, KE be joined. Now since the sides AK, AD of triangle AKD are equal to the sides BF, BG of triangle BFG, and the angles DAK and B contained by them are equal, [Margin: c — Elem. I.4] the bases KD and FG will also be equal. Again, since the sides AK, AE of triangle AKE are equal to the sides CH, CI, and the angle EAK is greater than the angle C — because the two angles DAE and B are posited to be greater than the angle C — [Margin: d — Elem. I.24] the base EK will also be greater than the base HI; [Margin: e — Elem. I.20] but the lines ED, DK are greater than the line EK. Therefore ED, DK will be much greater than HI. Since, then, DK has been shown to be equal to the line FG, DE and FG will also be greater than HI. Which is what was proposed.

Diagram. The first case of Proposition 22. At the left is the construction: the point K set above the triangle on base DE, with A as the vertex of the angle EAK (composed of EAD and DAK) and the joins KD, KE drawn. To the right are the three reference triangles for the given plane angles: triangle A on base DE, triangle B on base FG, and triangle C on base HI. Readable labelled points:

- K (upper left of the construction), A (vertex)
- D (base, left), E, F (along the base line)
- B (apex of second triangle), G, H (base)
- C (apex of third triangle), I (base)

CADAT — Now let AK fall in a straight line continuous with AE; this happens when the two angles DAE and B are equal to two right angles. And let AK be again set equal to AD, and let the straight line KD be joined. [Margin: f — Elem. I.4] Then, as before, KD will be equal to FG. [Margin: g — Elem. I.20] Now since the lines ED, DK are greater than the line KE, and KE is equal to the lines CH, CI by hypothesis and construction, ED and DK will also be greater than the two lines CH, CI; [Margin: h — Elem. I.20] but these are greater than HI. Therefore ED, DK will be much greater than HI. Since, then, DK has been shown to be equal to FG, DE and FG will also be greater than HI. Which is what was proposed.

Diagram. The second case of Proposition 22. The construction with K set above D, A on the line, and the base line D–E; alongside are the reference triangles with apex C on base H–I and apex B on base F–G. Readable labelled points:

- K (top), A (interior)
- D (base, left), E, F (base)
- C (apex), B (apex), G (base)

- H, I (base of the C-triangle)

Now let AK fall, lastly, on the side of AE, so that neither is the whole angle composed of the angles EAD and DAK, nor is EAK a straight line; which will finally come about when the two angles DAE and B are greater than two right angles. And let AK again be set equal to AD, and let the straight lines KD, KE be drawn. [Margin: i — Elem. I.4] Then, as before, KD will be equal to FG. [Margin: k — Elem. I.21] Now since the two lines DE, DK are greater than the two lines AE, AK, and AE, AK are equal to the two lines CH, CI by hypothesis and construction, DE and DK will also be greater than CH, CI; [Margin: l — Elem. I.20] but these are greater than HI. Therefore

Diagram. The third case of Proposition 22. A tall construction with K at the top, A within the triangle, and the base line D–E; to the right are the reference triangles with apex C on base H–I and apex B on base F–G. Readable labelled points:

- K (top), A (interior)

- C (apex), H, I (base of the C-triangle)
- B (apex), G (base)

Book XI (continued)

Proposition 22 (concluded)

(Continuing the third case: three plane angles, any two greater than the third, subtended by equal lines; the joining bases form a triangle.)

and so DE, DK will be much greater than HI. Therefore, since DK has been shown equal to FG, DE and FG will likewise be greater than HI — which is what was proposed. In the same way we shall conclude that DE, HI are greater than FG, if at C an angle is made equal [to the corresponding one]; and again that FG, HI are greater than DE, if at C, along FB, an angle equal [to the given one] is set up, and so on. [Margin: m 22.prim. — *Elements* I.22] Therefore, from the three straight lines DE, FG, HI a triangle can be constructed. And so, if there be three plane angles, and so forth — which was to be demonstrated.

Another proof. (ALITER.) Suppose the three angles A, B, C are equal. Then the bases DE, FG, HI will also be equal, [Margin: n 4.primi. — *Elements* I.4] and consequently any two of them are greater than the remaining one. But if only two of the angles are equal and the third is smaller, then two of the bases will be equal, [Margin: o 4.primi. — *Elements* I.4] and each of these will be greater than

the base of the third; [Margin: p 24.prim. — *Elements* I.24] so that again any two of them will be greater than the remaining one. And if one of them — say A — is the greatest, then whether the remaining two, B and C, are equal to each other or unequal, [Margin: q 24.prim. — *Elements* I.24] the base DE will be the greatest of all. Hence DE, FG will be greater than HI, and likewise DE, HI greater than FG.

I now say, further, that the straight lines FG, HI are also greater than the straight line DE. [Margin: r 23.primi. — *Elements* I.23] For let the angle DAK be made equal to angle B, and let AK be set equal to AD. The point K will then fall below DE, because the circumference of a circle described about A with radius AD passes through the points D, K, E, on account of the equality of the straight lines AD, AK, AE. Then let the straight lines DK, KE be joined. Now since the two angles B and C are assumed greater than angle DAE, and B is equal to angle DAK by construction, angle C will be greater than the remaining angle KAE. And because the sides AD, AK of triangle DAK are equal to the sides BF, BG of triangle BFG, and the contained angles DAK and B are equal, [Margin: s 4.primi. — *Elements* I.4] the base DK will be equal to the base FG. Again, because the sides CH, CI of triangle CHI are equal to the sides AK, AE of triangle AKE, and angle C has been shown greater than angle KAE, [Margin: t 24.primi. — *Elements* I.24] the base HI will be greater than the base KE. Therefore, since DK has been shown equal to FG, FG and HI will be greater than DK, KE. [Margin: u 20.prim. — *Elements* I.20] But DK, KE are greater than DE. Hence FG, HI will be much greater than DE — which is what was proposed.

Diagram. Three plane-angle figures set side by side, illustrating Proposition 22.

- Leftmost: a triangular figure (drawn as a folded pyramid) with apex **A** and base vertices **D** (lower left) and **E** (lower right), with a further vertex below the base DE [label F (?) — foxed] and the joining lines DK, KE of the construction.
- Middle: triangle with apex **B** and base **F–G**.
- Right: triangle with apex **C** and base **H–I** (G and H stand adjacent where the two triangles meet at the foot).

PROBL. 3. PROPOS. 23.

[Margin: xxiiij.]

From three plane angles, any two of which taken together are greater than the remaining one, to construct a solid angle. It is required, moreover, that those three angles together be less than four right angles.

Let there be three angles A, B, C, less than four right angles, and under this condition: that any two of them are greater than the remaining one. It is now required, out of the three angles A, B, C, to fashion a solid angle — one contained, that is, by three plane angles equal to the three given angles. Let there be laid down six lines enclosing the said angles, namely AD, AE, BF, BG, CH, CI, all equal; and let the bases DE, FG, HI subtend them. [Margin: a 22.vnde. — *Elements* XI.22] It is therefore possible that from DE, FG, HI a triangle be constructed. Let, then, the triangle KLM be constructed out of them, with side KL equal to the straight line DE, side LM equal to FG, and side KM equal to HI. [Margin: b 5.quarti. — *Elements* IV.5] Let a circle be described about the triangle KLM, whose center is N, from which let the straight lines NK, NL, NM be drawn. Then each of the lines enclosing the plane angles — namely AD, AE, and the rest — will be greater than any of the lines drawn from the center N. This will be shown as follows.

Let the center N fall first *inside* the triangle KLM — which indeed happens when the triangle is acute-angled [oxygonium], as is established from the corollary of Proposition 5, Book IV. Now if AD, AE be supposed *not* greater than NK, NL, they will be either equal or smaller. Let them be equal, then. Since the sides AD, AE of triangle ADE are equal to the sides NK, NL of triangle NKL, and the base DE is equal to the base KL, [Margin: c 8.primi. — *Elements* I.8] angle A will be equal to angle KNL. By the same argument, angle B will be equal to angle LNM, and angle C equal to angle MNK. Since, then, the three angles about N are equal to four right angles (from the corollary of Proposition 15, Book I), the three angles A, B, C will likewise be equal to four right angles. This is absurd, for they were assumed less than four right angles. Therefore AD, AE are not equal to NK, NL.

I say they are not smaller either. For if AD, AE were smaller than NK, NL, let NO, NP be cut off equal to AD, AE, and let the straight line OP be drawn. Since, then, as NK is to NO, so is NL to NP — the antecedents being equal to each other and the consequents to each other — [Margin: d 2.sextri. — *Elements* VI.2 [digit slightly foxed]] the sides NK, NL of triangle NKL will be cut proportionally, and consequently OP will be parallel to KL. [Margin: e 29.prim. — *Elements* I.29] Hence the angles NOP, NPO will be equal to the angles NKL, NLK, and triangle NOP will be equiangular with triangle NKL. [Margin: f 4.sextri. — *Elements* VI.4] Therefore, as NK is to KL, so is NO to OP. But NK is greater than NO. [Margin: g 14.quin. — *Elements* V.14] Therefore KL also — that is, DE, which is equal to KL — will be greater than OP. And so, since the sides AD, AE of triangle ADE are equal to the sides NO, NP of triangle NOP, while the base DE is greater than the base OP, [Margin: h 25.primi. — *Elements* I.25] angle A will also be greater than angle ONP. By the same reasoning, angle B will be shown greater than angle LNM, and angle

C greater than angle MNK. Since, then, the three angles at N are four right angles (from the corollary of Proposition 15, Book I), the three angles A, B, C will be greater than four right angles. This is absurd, for they are assumed less than four right angles. Therefore AD, AE are not smaller than NK, NL; but neither are they equal. Hence they are greater.

Diagram. The construction for Proposition 23, first case (center N inside triangle KLM). To the left stand the three given plane-angle triangles and the auxiliary segment; to the right the circumscribed-circle construction.

- Triangle with apex **A** and base **D–E** (angle A).
- Short horizontal segment labelled **T** (the auxiliary line used later).
- Triangle with apex **B** and base **F–G** (angle B).
- Triangle with apex **C** and base **H–I** (angle C).
- Circle with center **N**, containing the inscribed triangle **K** (top), **L** (lower left), **M** (right); with **O** on NK and **P** on NL (the cut-off segments), and the apex **V** at the top (the vertex of the solid angle raised on the perpendicular NV).

Suppose, further, that AD, AE be believed to be equal to NK, NL. Then BF, BG will also be equal to the same NK, NL

— that is, to NK, NL. Since, then, NK is equal to NM, BF and BG will be equal to the straight line LM; but LM was laid down equal to FG. Therefore BF, BG are likewise equal to the straight line FG. [Margin: i 20.prim. — *Elements* I.20] But BF, BG are also *greater* than FG. This [recte: est] is absurd. Therefore AD, AE are not equal to NK, NL.

But if AD, AE be believed smaller than NK, NL, then BF, BG will also be smaller than NK, NL. Since, then, NK is equal to NM, BF, BG will be smaller than the straight line LM; but LM was laid down equal to FG. Therefore BF, BG are likewise smaller than the straight line FG. This is absurd, [Margin: k 20.prim. — *Elements* I.20] since they are greater. Therefore AD, AE are not smaller than NK, NL; nor equal. Hence they are greater.

Let the center N fall, lastly, *outside* the triangle KLM, below the side LM — which happens when the angle LKM is obtuse, as is clear from the said corollary of Proposition 5, Book IV. If, then, AD, AE be said to be equal to NK, NL — since the base DE is also laid down equal to the base KL — [Margin: l 8.primi. — *Elements* I.8] angle A will be equal to angle KNL. By the same reasoning, angle C will be equal to angle KNM. Hence the whole angle LNM will be equal to the angles A and

C together. But these two are, by hypothesis, greater than angle B. Therefore angle LNM will also be greater than angle B. Again, because the sides NL, NM of triangle NLM are equal to the sides BF, BG of triangle BFG, and the base LM is equal to the base FG, [Margin: m 8.prim. — *Elements* I.8] angle LNM will be equal to angle B. But we also showed it to be greater. This is absurd. Therefore AD, AE are not equal to NK, NL.

But if AD, AE be believed smaller than NK, NL — if NO, NP be cut off equal to AD, AE, and the straight line OP be drawn — it will be demonstrated, as in the first case, that angle A is greater than angle ONP, and by the same reasoning that angle C is greater than angle KNM. [Margin: n 23.prim. — *Elements* I.23] Let the angle ONQ be made equal to A, and the angle ONR equal to C, and let NQ, NR be set equal to AD, AE, and let OQ, OR be joined. OQ will fall below OP, because the circumference of a circle described about N with radius NO passes through the points O, P, Q, since the straight lines NO, NP, NQ are equal. [Margin: o 29.primi. — *Elements* I.29] Hence, since angle PON is equal to angle LKN — the exterior to the interior — angle QON will be smaller than angle LKN. By the same reasoning it will be shown that angle NOR is smaller than angle NKM, if OS be drawn parallel to KM; for OR will likewise fall below OS. Therefore the whole angle LKM will be greater than the whole angle QOR. Now since the sides NO, NQ of triangle NOQ are equal to the sides AD, AE, and angle ONQ is equal to angle A by construction, [Margin: p 4.prim. — *Elements* I.4] OQ will be equal to DE — that is, to KL. In the same way, OR will be equal to KM. When now the straight line QR has been joined, since the sides KL, KM of triangle LKM are equal to the sides OQ, OR of triangle OQR, and angle LKM is greater than angle QOR, as we have shown, [Margin: q 24.prim. — *Elements* I.24] the base LM — that is, FG — will be greater than the base QR. Since, then, the sides BF, BG of triangle BFG are equal to the sides NQ, NR of triangle NQR, and the base FG is greater than the base QR, [Margin: r 25.prim. — *Elements* I.25] angle B will be greater than angle QNR. Again, because angle ONQ has been made equal to A and angle ONR equal to C, the whole angle QNR will be equal to the two angles A and C together. But A and C are assumed greater than angle B. Therefore angle QNR will also be greater than angle B. This is absurd, since B was shown greater than angle QNR. Therefore AD, AE are not smaller than NK, NL; nor equal. Hence they are greater.

Diagram. Reprint of the given plane-angle triangles together with the circle construction, accompanying the second-case discussion.

- Triangle with apex A and base D–E.
- Triangle with apex C and base (H–I).

- Triangle with apex **B** and base (I–F).
- Circle with center **N**, inscribed points **K** (upper right), **L** (left), **M** (right), and apex **V** at the top; a broken line runs from **V** toward **L**.

Diagram. The construction for the third case of Proposition 23 (center **N** outside triangle **KLM**, below **LM**).

- Triangle with apex **A** and base **D–E**; triangle with apex **C** and base **H–I**; triangle with apex **B** and base **F–G** (below).
- Circle with center **N** (at the bottom), inscribed triangle with **K** (top), **L** (left), **M** (right); apex **V** at the top and **O** near the center; interior points **P** (left of **N**), **Q** (lower left), **R** (right of **N**), **S** (near **M**) — the points of the **OQ**, **OR**, **QR**, **OS** construction. (Several interior labels lie in foxed regions.)

Now since the straight lines **AD**, **AE** are greater than the straight lines **NK**, **NL**, wherever the center **N** may lie, the straight line **AD** is able to exceed the straight line **NK** by the square on the line **T**, by the lemma of Proposition 14, Book X — that is, so that the square on **AD** is equal to the squares on **NK** and **T** together. [Margin: s 12.vndec. — *Elements* XI.12] From the center **N** let there be raised, perpendicular to the plane of the circle **KLM**, the perpendicular **NV**, equal to the straight line **T**, and let **KV**, **LV**, **MV** be joined. Since, then, **NV** is a straight line perpendicular to the plane of the circle **KLM**, it will be perpendicular to the straight lines **NK**, **NL**, **NM**, by Definition 3 of this book; [Margin: t 47.primi. — *Elements* I.47] and consequently the square on **VK** will be equal to the squares on **KN**, **NV**. Since, then, the square on **AD** is also equal, by construction, to the same squares on **KN**, **NV**, the squares on **VK** and **AD** will be equal to each other. Hence the straight lines **VK**, **AD** will be equal. Again, because the sides **VN**, **NK** of triangle **VNK** are equal to the sides **VN**, **NL** of triangle **VNL**, and the contained angles **VNK**, **VNL** are right, [Margin: u 4.primi. — *Elements* I.4] the base **VK** will be equal to the base **VL**; and by the same reasoning the straight line **VM** as well. Therefore the three straight lines **VK**, **VL**, **VM** are equal to one another. But **VK** has been shown equal to **AD**. The three straight lines **VK**, **VL**, **VM** are therefore equal to **AD**, and thereby to **AE**, **BF**, **BG**, **CH**, **CI**. And so, since the sides **VK**, **VL** of triangle **VKL** are equal to the sides **AD**, **AE** of triangle **ADE**, and the base **KL** to the base **DE**, [Margin: x 8.primi. — *Elements* I.8] angle **KVL** will be equal to angle **A**. Not otherwise shall we demonstrate that angle **LVM** is equal to angle **B**, and angle **KVM** equal to angle **C**. Hence the solid angle **V** is contained by the three plane angles **KVL**, **LVM**, **MVK**, which are equal to the three given plane angles **A**, **B**, **C**. Therefore, out of three plane angles, and so forth — which was to be done.

THEOR. 21. PROPOS. 24.

[Margin: xxiv.]

If a solid is contained by parallel planes, its opposite faces are similar and equal parallelograms.

Let the parallelepiped be ABEF (for it is of this that the proposition is to be understood), contained, according to Definition 30 of this book, by the six quadrilateral figures AC, CF, FH, HA, AF, BE, of which any two opposite are parallel. I say that any pair of opposite faces are similar and equal parallelograms. For when the parallel planes BG, CF are cut by the plane AC, [Margin: a 16.vnde. — *Elements* XI.16] the common sections AB, CD will be parallel. Similarly, when the parallel planes AF, BE are cut by the plane AC, the common sections AD, BC will be parallel. And consequently ABCD is a parallelogram, a quadrilateral figure. Not otherwise shall we show that the remaining quadrilateral figures are parallelograms.

I now say that the opposite parallelograms are similar and equal. For since the straight lines AB, BH are parallel to the straight lines DC, CE, and lie not in the same plane but in opposite ones, [Margin: b 10.vnde. — *Elements* XI.10] the angles ABH, DCE will be equal; and by the same argument the remaining angles of parallelogram BG will be equal to the remaining angles of parallelogram CF. [Margin: c 34.primi. — *Elements* I.34] Now since AB is equal to DC in parallelogram AC, and BH is equal to CE in parallelogram BE, it will be that as AB is to BH, so is DC to CE; and consequently, as BH is to HG, so is CE to EF, and so on, for the same cause. Therefore the sides of the parallelograms BG, CF about the equal angles will be proportional, and consequently the parallelograms themselves similar. Now, when the diagonals AH, DE are drawn, [Margin: d 34.prim. — *Elements* I.34] since the sides AB, BH of triangle ABH are equal to the sides DC, CE of triangle DCE, [Margin: e 10.vnd. — *Elements* XI.10] and angle ABH is equal to angle DCE, as has been shown, [Margin: f 4.prim. — *Elements* I.4] the triangles ABH, DCE will be equal to each other. [Margin: g 34.prim. — *Elements* I.34] Hence, since the triangles ABH, DCE are halves of the parallelograms BG, CF, [these are] equal to each other. Similarly we shall demonstrate that the opposite parallelograms AC, GE and AF, BE are similar and equal. If, therefore, a solid is contained by parallel planes, its opposite faces are parallelograms, similar and equal, and so forth — which was to be demonstrated.

Diagram. The parallelepiped ABEF for Proposition 24. A rectangular box drawn in oblique projection.

- Top face vertices: **A** (front-upper), **G** (rear-right upper), **B** (left upper), and a fourth top vertex at center labelled **H** [?] (foxed).
- Bottom face vertices: **C** (front-left lower), **E** (front-center lower), **D** (rear-center lower), **F** (right lower).
- Diagonals **AH** and **DE** are drawn across opposite faces.

THEOR. 22. PROPOS. 25.

[Margin: xxv.]

If a parallelepipedal solid is cut by a plane parallel to the opposite faces, then as base is to base, so is solid to solid.

Let the parallelepiped **ABCD** be cut by the plane **EF**, parallel to the opposite planes **AD**, **BC**. I say that, as the base **AG** is to the base **BG**, so is the solid **AEFD** to the solid **BEFC**. For let the parallelepiped **ABCD** be conceived as produced on either side to any extent whatever; and on **AB**, when it has been drawn out, let there be taken any number of straight lines **AK**, **KL** equal to **AE**, and any number of straight lines **BM**, **MN**, **NO** equal to **EB**. Then through the points **K**, **L**, **M**, **N**, **O** let there be drawn the planes **KP**, **LQ**, **MR**, **NS**, **OT** parallel to the planes **AD**, **EF**, **BC**, by the scholium of Proposition 15 of this book. Since, then, the solid **AEFD** is contained by parallel planes by hypothesis, it will be a parallelepiped by definition, [Margin: a 24.vnde. — *Elements* XI.24] and will have its opposite planes similar and equal parallelograms. In the same way there will be the parallelepipeds **AKPD**, **KLQP**, **EBCF**, **BMRC**, **MNSR**, **NOTS**, **ELQF**, **EOTF**; and they will have their opposite planes similar and equal parallelograms. [Margin: b 36.primi. — *Elements* I.36] Now since the parallelograms **AG**, **KV**, **LX**, standing on equal bases **AE**, **AK**, **KL**, are equal, and similar too — [Margin: c 29.prim. — *Elements* I.29] since the angles of the one are equal to the angles of the others, and the sides about the angles of the one equal to the sides about the angles of the others, and therefore proportional. And by the same reasoning the parallelograms **AY**, **KZ**, **Lx** are equal and similar. Since, then, the parallelograms **AD**, **KP**, **LQ** are likewise equal and similar, the three planes **AG**, **AY**, **AD** of the solid **AEFD** will be equal and similar to the three planes **KV**, **KZ**, **KP** of the solid **AKPD**, and to the three planes **LX**, **L**, **LQ** of the solid **KLQP**. [Margin: d 24.vnde. — *Elements* XI.24] Moreover, the three planes in each solid are equal and similar to the three remaining opposite ones in the same solid, namely **AG** to **ZF**, **AY** to **VF**, and **AD** to **EF**, and so on. Therefore, by Definition 10 of this book, the solids **AEFD**, **AKPD**, **KLQP** are equal. By the same argument the solids **EBCF**, **BMRC**, **MNSR**, **NOTS** will be shown equal.

Hence, whatever multiple the base LG is of the base AG, the solid LEFQ will be the same multiple of the solid AEFD; and whatever multiple the base OG is of the base BG, the solid OEFT will be the same multiple of the solid BEFC. Now if the base LG (the multiple of the base AG, of the first magnitude) is equal to the base OG (the multiple of the base BG, of the second magnitude), the solid LEFQ (the multiple of the solid AEFD, of the third magnitude) is likewise equal to the solid OEFT (the multiple of the solid BEFC, of the fourth magnitude), because, the bases LG, OG being equal, the six parallelograms of the solid LEFQ are also equal and similar to the six parallelograms of the solid OEFT. But if the base is greater than the base, the solid too is greater than the solid; and if smaller, smaller — in whatever multiplication this be made. Therefore, by Definition 6, Book V, as the base AG (the first magnitude) is to the base BG (the second magnitude), so will the solid AEFD (the third magnitude) be to the solid BEFC (the fourth magnitude). By the same reasoning it will be demonstrated that solid is to solid as the base DY is to the base CY, and as the base AY is to the base BY, and as the base DG is to the base CG. If, then, a parallelepipedal solid be cut by a plane, and so forth — which was to be shown.

Diagram. The long divided parallelepiped for Proposition 25. A parallelepiped drawn in oblique projection and partitioned by successive parallel planes into equal cells. The scan is heavily foxed through the figure and many compartment labels are indistinct.

- Front bottom edge (left to right): L, K, A, E, B, M, N, O.
- Front top edge (left to right): Q, P, D, F, C, R, S, T.
- Rear top edge / interior compartments (left to right): β (beta), X, V, G, I, δ (delta), and the numeral labels 3, 8 [rear-interior labels partly foxed].
- Additional interior/rear-bottom labels (Greek letters and numerals 2, 9) fall in foxed regions and cannot be read with confidence [?].

SCHOLIUM.

This proposition can also be adapted to every prism. For if any prism whatever be cut by a plane parallel to the opposite planes, then, as base is to base, so will solid be to solid. Let there be first the prism ABCDEF, whose opposite planes are the triangles ABC, DEF, and let it be cut by the plane GHI, parallel to the opposite planes. I say that, as the base AI is to the base FI, so is the solid ABCIHG to the solid FEDIHG. For let the prism ABCDEF be conceived as produced on either side to any extent whatever...

(The Scholium continues onto the following page.)

and from AF, produced in both directions, let any number of segments AK, KL be taken equal to AG, and any number of segments FM, MN, NO equal to FG. Then through the points K, L, M, N, O let the planes KPQ, LRS, MTV, NXY, OZ α be drawn parallel to the planes ABC, GHI, FED, by the scholium to Proposition 15 of this book. Now since the parallel planes ABC, GHI are cut by the plane AI, [Margin: c $\rightarrow$ *Elements* XI.16] their common sections AC, GI are parallel; but AG, CI are also parallel by hypothesis, because AD is a parallelogram. Therefore AI is a parallelogram. Again, since the parallel planes ABC, GHI are cut by the plane AH, [Margin: f $\rightarrow$ *Elements* XI.16] their common sections AB, GH are parallel; and AG, BH are likewise parallel, because AE is a parallelogram. Therefore AH is a parallelogram. In the same way CH is shown to be a parallelogram. Now the sides AC, AB of triangle ABC are equal to the sides GI, GH of triangle GHI, [Margin: g $\rightarrow$ *Elements* I.34] since AC equals GI and AB equals GH; [Margin: h $\rightarrow$ *Elements* XI.10] and the angles CAB, IGH are also equal, because the lines CA, AB are parallel to the lines IG, GH and do not lie in the same plane. [Margin: i $\rightarrow$ *Elements* I.4] Therefore the triangles ABC, GHI are equal to one another and equiangular. [Margin: k $\rightarrow$ *Elements* VI.4] Hence the sides about their equal angles will be proportional, and for that reason the triangles will be similar.

Therefore the solid ABCIHG — contained by the two opposite planes ABC, CHI, which are equal and similar, together with the parallelograms AI, IB, BG — is a prism. In the same way ABCQPK, KPQSRL, FEDIHG, FEDVTM, MTVYXN, NXY α ZO, LRSIHG, OZ α IHG are prisms.

Diagram. A long triangular prism lying horizontally, partitioned by the parallel cutting planes into eight equal triangular prisms; each cross-section is drawn as a vertical triangle with an internal diagonal. The prism has three parallel lengthwise edges, so the labels form three rows.

- Bottom edge (left to right): L, K, A, G, F, M, N, O
- Middle edge (left to right): R, P, B, H, E, T, X, Z
- Top edge (left to right): S, Q, C, I, D, V, Y, α (Greek alpha)
- The eight triangular cross-sections (bottom / middle / top vertices): (L, R, S), (K, P, Q), (A, B, C), (G, H, I), (F, E, D), (M, T, V), (N, X, Y), (O, Z, α)

Now since the parallelograms AI, KC, LQ are equal and similar, and likewise AH, LB, LP and CH, QB, SP, all the planes of the prisms ABCQPK, KPQSRL will be equal and similar. Hence, by Definition 10 of this book, the prisms ABCIHG, ABCQPK, KPQSRL are equal. By the same reasoning the prisms FEDIHG, FEDVTM, MTVYXN, NXY α ZO are equal. Therefore, however many times the base LI is a multiple of the base AI, so many times will the prism LRSIHG be a multiple of the prism

ABCIHG; and however many times the base OI is a multiple of the base FI, so many times will the prism OZαIHG be a multiple of the prism FEDIHG. Now if the base LI (a multiple of the base AI, the first magnitude) is equal to the base OI (a multiple of the base FI, the second magnitude), then the prism LRSIHG (a multiple of the prism ABCIHG, the third magnitude) is also equal to the prism OZαIHG (a multiple of the prism FEDIHG, the fourth magnitude); for when the bases LI, OI are equal, all the planes of the prism LRSIHG are also equal and similar to all the planes of the prism OZαIHG. And if the base LI is greater than the base OI, the first prism is likewise greater, and if less, less — in whatever multiplication this is carried out. Therefore, by Definition 6 of Book V, as the base AI, the first magnitude, is to the base FI, the second magnitude, so is the prism ABCIHG, the third magnitude, to the prism FEDIHG, the fourth magnitude. In the same way it will be shown that prism is to prism as the base AH is to the base FH, and as the base CH is to the base DH. Which was the thing proposed.

Next, let ABCDEFGHIK be a prism whose opposite planes are polygonal — namely pentagons — and let it be cut by the plane LMNOP. I say once more, as before, that as the base CM is to the base NG, so is the solid ABCDELMNOP to the solid LMNOPFGHIK.

Diagram. A pentagonal prism seen in oblique view, its two pentagonal faces resolved into triangles and cut across the middle by the pentagonal plane LMNOP, so that it is divided into a front block and a back block of three triangular prisms each. Readable vertices: A (top left), L (top centre), B (left), M (centre), G (upper right), K (far right), E (interior left), P (interior centre), C (lower left), N (lower centre), H (lower right), D (bottom left), O (bottom centre). The front-pentagon / cutting-plane / back-pentagon correspondence is $A \rightarrow L \rightarrow F$ [?], $B \rightarrow M \rightarrow G$, $C \rightarrow N \rightarrow H$, $D \rightarrow O \rightarrow I$ [?], $E \rightarrow P \rightarrow K$.

For if the opposite parallel planes are resolved into triangles, the prism too will be resolved into the same number of prisms whose opposite planes are triangles. Hence, as the base BP is to the base MK, so will the prism ABEPML be to the prism LMPKGF, by what has already been demonstrated. In the same way, as the base CP is to the base NK, so will the prism BCEPMN be to the prism MNPKGH, and the prism CDEPNO to the prism NOPKHI. [Margin: $l \rightarrow$ *Elements* VI.1] But as BP is to MK and CP to NK, so is the straight line EP to the straight line PK — that is, as CN is to NH; and as CN is to NH, so is CM to NG. Therefore the prisms ABEPML, BCEPMN, CDEPNO have to the prisms LMPKGF, MNPKGH, NOPKHI the same ratio that CM has to NG, and consequently the same ratio to one another. [Margin: $m \rightarrow$ *Elements* V.12] And as one is to one, so are all to all. Therefore, as the prism

BCEPMN is to the prism MNPKGH — that is, as the base CM to the base NG — so will the prism ABCDELMNOP, composed of three, be to the prism LMNOPFGHIK, made up of three. Which was the thing proposed. The demonstration will be exactly the same for any other prism.

This same result can, however, be shown for every prism by the demonstration we used for a prism whose opposite planes are similar triangles. For if the same construction is made, the prism being produced in both directions, all the parallel cutting planes will be equal and similar to one another, [Margin: n → *Elements* XI.16] because their sides are parallel to the sides of the [opposite] planes, [Margin: o → *Elements* XI.10] and consequently contain equal angles, and so on. From this, as before, it will be shown that the prisms on the one side are equal to one another, and likewise the prisms on the other side, and so on.

COROLLARIVM.

From these things it follows that if any prism is cut by a plane equidistant from the opposite planes, the section is a figure equal and similar to the opposite planes — just as it was demonstrated in the earlier prism that the triangle GHI is equal and similar to triangle ABC, and therefore to triangle DEF. For the demonstration is the same in every case. The same may be said of the parallelepiped.

PROBL. 4. PROPOS. 26.

[Margin: xxvi.]

On a given straight line, and at a given point on it, to construct a solid angle equal to a given solid angle.

Let a solid angle be constructed at the point A on the given straight line AB, equal to the solid angle C, which is contained by the three plane angles DCE, DCF, FCE not lying in the same plane. [Margin: a → *Elements* I.11] From F let a perpendicular FG be drawn to the plane through CD, CE, and let the straight lines DF, DG, EF, EG, CG be joined. Then cut off AH equal to CD, [Margin: b → *Elements* XI.23] make the angle HAI equal to the angle DCE, and let the straight line AI be equal to the straight line CE. Again, in the plane through AH, AI construct the angle HAL equal to the angle DCG (which lies in the plane drawn through CD, CE), with the straight line AL equal to the straight line CG. [Margin: c → *Elements* XI.12] From L erect a perpendicular LK to the plane in which the three lines AH, AL, AI lie, let it be set equal to FG, and join the straight line KA. I say that the solid angle A, contained by the three plane angles HAI, HAK, KAI, is equal to the given

solid angle C. For when the straight lines HK, HL, IK, IL have been joined: since the sides AH, AL of triangle AHL are equal to the sides CD, CG of triangle CDG, and the angles HAL, DCG are equal by construction, [Margin: d → *Elements* I.4] the bases HL, DG will be equal. Again, since, when the equal angles HAL, DCG are subtracted from the equal angles HAI, DCE, the remainders LAI, GCE are equal — then, since the sides AL, AI of triangle ALI are equal to the sides CG, CE of triangle CGE by construction,

Diagram. Two triangular pyramids (tetrahedra) drawn side by side in oblique view. Left pyramid (the constructed solid angle A): apex A (top), with L (interior), H (lower left), I (lower right) and B (bottom). Right pyramid (the given solid angle C): apex C (top), with G (interior, foot of the perpendicular FG), D (lower left), E (lower right) and F (bottom).

the bases LI, GE will also be equal. [Margin: e → *Elements* I.4] And since the sides LH, LK are equal to the sides GD, GF, and the angles HLK, DGF are right by Definition 3 of this book, [Margin: f → *Elements* I.4] the bases HK, DF will also be equal. Hence, since the sides AH, AK of triangle AHK are equal to the sides CD, CF of triangle CDF by construction — (for since AL, LK are equal to the sides CG, GF by construction, and contain equal angles, namely right angles, by Definition 3 of this book, [Margin: g → *Elements* I.4] the bases AK, CF will be equal) — [Margin: h → *Elements* I.8] the angles HAK, DCF will also be equal. Finally, since the sides LI, LK are equal to the sides GE, GF, and the angles ILK, EGF are right by Definition 3 of this book, [Margin: i → *Elements* I.4] the bases IK, EF will be equal; and since the sides AI, AK of triangle AIK are equal to the sides CE, CF of triangle CEF by construction, [Margin: k → *Elements* I.4] the angles IAK, ECF will also be equal. Therefore the three plane angles HAI, HAK, KAI, which compose the solid angle A, are equal to the three plane angles DCE, DCF, FCE, which compose the solid angle C; and consequently the solid angle A is equal to the solid angle C. Thus on the given straight line, and at a given point on it, we have constructed a solid angle equal to a given solid angle. Which was to be done.

SCHOLIVM.

If a given solid angle is contained by more than three plane angles, straight lines must be drawn subtending all the plane angles and lying in one and the same plane (namely in that plane which cuts all the straight lines of the plane angles), so that they form a plane polygon and produce a certain many-sided pyramid. For if the polygonal figure is resolved into triangles, there will be as many triangular pyramids as there are triangles contained in the polygon. If, then, solid angles are constructed equal to the solid angles of all the triangular pyramids,

each contained by three plane angles, the whole solid angle so constructed will be equal to the whole given solid angle.

Diagram. Two many-sided pyramids drawn side by side, each seen from above its apex, with the base polygon resolved into triangles by lines drawn from the apex. Left pyramid: apex A, with base vertices B (upper left), F (centre), E (upper right), C (lower left), D (lower right) — the pentagon BCDEF. Right pyramid: apex G, with base vertices H (upper left), M (centre), L (upper right), I (lower left), K (lower right).

For example, if a solid angle equal to the solid angle A — contained by the five plane angles BAC, CAD, DAE, EAF, FAB — is to be constructed, straight lines BC, CD, DE, EF, FB must be drawn subtending the plane angles, so that the pentagon BCDEF is formed, which is resolved into the three triangles BCF, FCD, DEF. Then, for the solid angle A contained by the three plane angles BAC, CAF, FAB, a solid angle G is to be constructed equal to it, contained by the three plane angles HGI, IGM, MGH. And for the solid angle A contained by the three plane angles CAF, FAD, DAC, an equal solid angle G, contained by the three plane angles IGM, MGK, KGI. And finally, for the solid angle A contained by the three plane angles DAE, EAF, FAD, an equal solid angle G, contained by the three plane angles KGL, LGM, MGK. For in this way the whole solid angle G will become equal to the whole solid angle A. And in this manner a solid angle equal to any given solid angle will be constructed.

PROBL. 5. PROPOS. 27.

[Margin: xxvii.]

On a given straight line, to describe a solid parallelepiped similar and similarly situated to a given solid parallelepiped.

Let it be required, on the given straight line AB, to describe a parallelepiped similar and similarly situated to the parallelepiped CD. [Margin: a → *Elements* XI.26] At the straight line AB and its point A, construct a solid angle equal to the solid angle C, so that the three plane angles HAI, IAB, BAH are equal to the three plane angles ECG, GCF, FCE. Then, [Margin: b → *Elements* VI.12] as CF is to CG, so make AB to AI, and as CG is to CE, so AI to AH; and, ex aequali, as CF is to CE, so will AB be to AH.

Diagram. Two solid parallelepipeds (rectangular boxes) drawn in oblique view. Left box (the constructed solid AK): K (top rear), I (upper interior), H (front left), A

(bottom front left), B (bottom front right). Right box (the given solid CD): D (top rear right), G (interior), E (front left), C (bottom front left), F (bottom front right).

After this, complete the parallelepiped AK, by completing the parallelograms BH, HI, IB and drawing through I, B, H the planes IK, BK, HK parallel to the parallelograms BH, HI, IB. I say that the parallelepiped AK is similar and similarly situated to the parallelepiped CD. For since the angles BAH, FCE are equal, and the sides about them proportional — namely, as BA is to AH, so FC to CE — by construction, the parallelograms HB, EF will be similar and similarly situated. For the same reason the parallelograms HI, EG and IB, GF will be similar and similarly situated. Therefore the three planes BH, HI, IB of the solid AK are similar and similarly situated to the three planes FE, EG, GF of the solid CD. [Margin: c → *Elements* XI.24] But in each solid any three planes are equal and similar to the three remaining opposite ones. Hence the six planes of the solid AK are similar and similarly situated to the six planes of the solid CD; and consequently, by Definition 9 of this book, the solids AK, CD are similar and similarly situated. Therefore on the given straight line we have described a parallelepiped similar and similarly situated to the given solid. Which was to be done.

THEOR. 23. PROPOS. 28.

[Margin: xxviii.]

If a solid parallelepiped is cut by a plane through the diagonals of opposite faces, the solid is bisected by that plane.

Let AB be a parallelepiped in which the opposite planes are AH, EB, whose diagonals (or diameters) are the straight lines CG, DF. Now since each of CD, GF is parallel [Margin: a → *Elements* I.34] and equal to AE, since CE, GE are parallelograms, [Margin: b → *Elements* XI.9] CD, GF will be both parallel and equal to one another; [Margin: c → *Elements* I.33] and consequently the lines CG, DF that join them will be parallel and equal, and therefore lie in one plane. I say that the plane drawn through CG, DF cuts the parallelepiped AB in half.

Diagram. A single solid parallelepiped in oblique view, with the bisecting plane drawn through it. Vertices: F (top rear left), B (top rear right), E (upper front left), D (upper rear right), G (lower front left), H (lower rear right), A (bottom front left), C (bottom front centre). The diagonals CG and DF of the opposite faces are drawn.

[Margin: d → *Elements* XI.24] For since the planes AH, EB are equal and similar parallelograms, their halves — namely the triangles AGC, GCH and EFD, FDB — will be equal to one another; and the sides about the equal angles GAC, CHG, FED, DBF are proportional. [Margin: e → *Elements* VI.6] Therefore the said triangles will also be similar. [Margin: f → *Elements* XI.24] Since, then, the parallelogram AF is equal and similar to the parallelogram CB, and AD to GB, and CF is common, the two triangles AGC, EFD and the parallelograms AF, AD, CF of the prism ACGFED will be equal and similar to the two triangles HCG, BDF and the parallelograms CB, BG, CF of the prism HGCDBF; and therefore, by Definition 10 of this book, the prisms will be equal. And since these make up the parallelepiped AB, the parallelepiped AB will be cut in half. Therefore, if a solid parallelepiped is cut by a plane, and so on. Which was to be demonstrated.

THEOR. 24. PROPOS. 29.

[Margin: xxix.]

Solid parallelepipeds constructed on the same base and of the same height, whose standing edges lie on the same straight lines, are equal to one another.

On the base AB, at the same height — that is, between the same parallel planes — let two parallelepipeds ACDE, AFGE be constructed, whose standing edges, going out from the four angles of the base, lie on the same lines: namely AI, AK, EL, EM on the straight line IM, and HC, HF, BD, BG on the straight line CG. I say that they are equal to one another.

Diagram. A solid parallelepiped in oblique view with internal construction lines. Readable vertices: C (top left), F (top centre), D (top right), G (top far right), H (left), B (centre, interior), I (lower left), K (lower centre), L (lower right), M (far right), A (bottom left), E (bottom centre).

[Margin: a → *Elements* I.35] For since the parallelograms AL, AM, constructed on the same base AE and between the same parallels, are equal, then, when the common trapezium AELK is taken away, the triangles AIK, ELM will also be equal. [Margin: b → *Elements* I.34] Now since all the sides of triangle AIK are equal to all the sides of triangle HCF, the triangle AIK will be equiangular and equal to triangle HCF, by what we showed at Proposition 8 of Book I; [Margin: c → *Elements* VI.4] and therefore they will have the sides about their equal angles proportional, and so will be similar to one another. For the same reason triangle ELM will be equal and similar to triangle BDG. [Margin: d → *Elements* XI.24]

Again, the parallelogram AC is equal and similar to the parallelogram ED, and by the same reasoning the parallelogram AF to the parallelogram EG; [Margin: e → *Elements* I.20] and also IF to LG, since the bases IK, LM are equal. ([Margin: f → *Elements* I.54 [?] — Book I has only 48 propositions; probable compositor error or misread] For since the straight lines IL, KM are equal to AE, they will also be equal to one another; hence, when the common part KL is taken away, IK, LM will be equal.) Therefore all the planes of the prism AIKFCH will be equal and similar to all the planes of the prism ELMGDB. Hence, by Definition 10 of this book, the said prisms are equal; and consequently, when the common solid AHFKLDBE is added, the parallelepipeds on the same base will be equal, and so on. Which was to be demonstrated.

SCHOLIUM.

This proposition is very similar to Proposition 35 of Book I. For what is there demonstrated about parallelograms is here demonstrated about parallelepipeds, by almost the same means, provided that in place of the triangles prisms are assumed, as is clear from the demonstration. Hence the remaining two cases — namely when the point K falls on the point L, or beyond L — will be demonstrated in the same way, as appears in these figures. For in the second case, if from the equal parallelograms AL, AM the common triangle ALE is taken away, the remaining triangles AIK, ELM will be equal. Hence, as before, the prisms AIKFCH, ELMGDB will be equal. Therefore, when the common prism AKEBHD is added, the parallelepipeds ACDE, AFGE will become equal.

In the third case, if from the equal parallelograms AL, AM the common triangle ANE is taken away, the remaining trapezia AILN, NKME will be equal; and if the common triangle KLN is added to these, the whole triangles AIK, ELM will become equal. Hence, as before, the prisms AIKFCH, ELMGDB will be equal; and if the common prism KLNODF is taken away from them — (for the common section of the planes AF, DE is the straight line NO) — there will remain the solid contained by the planes AILN, NOHA, AICH, HCDO, CDLI, DLNO, equal to the solid contained by the planes ENKM, MKFG, GFOB, FKNO, BGME, EBON. If, then, the common prism AENOBH is added to each, the parallelepipeds ACDE, AFGE will become equal to one another.

Diagram. The first of two solid parallelepipeds drawn side by side for the scholium (the second case), in oblique view with internal construction lines and heavy foxing. Readable vertices: C, D, G (top), F, H (left), B (interior), L, K (lower centre), M (right), A, E (bottom). Foxing obscures several interior labels.

Diagram. The second of the two scholium parallelepipeds (the third case), in oblique view with internal construction lines and foxing. Readable vertices: C, D, F (top), H (left), O (interior), E (centre), I, L, K, N (lower), A (bottom). Several interior labels obscured by foxing.

THEOR. 25. PROPOS. 30.

[Margin: xxx.]

Solid parallelepipeds constructed on the same base and of the same height, whose standing edges do not lie on the same straight lines, are equal to one another.

On the base AB, at the same height — that is, between the same parallel planes — let the parallelepipeds AIDK, AMFK be constructed, whose standing edges going out from the four angles of the base — AC, AE, KG, KL; HI, HM, BD, BF — do not lie on the same straight lines; that is, neither do CI, GD, when produced, pass through the points M, E, F, L, nor do CG, ID when produced, and so on. I say that the parallelepipeds AIDK, AMFK are equal. For since the planes CD, EF, opposite to the base AB, lie in the same plane (on account of the equal height of the parallelepipeds), let the straight lines CG, ID be produced in that plane, of which CG cuts EM, LF, produced, at the points N, O; and ID [cuts] the same...

Book XI (continued)

Proposition 30 (concluded)

(Continuing the demonstration begun in the previous pages: the produced lines CG and ID cut EM and LF) — at the same points P and Q; and let the straight lines AN, KO, HP, BQ be joined.

[Margin: a — 34.pri. (*Elements* I.34)] Now the straight lines PQ and MF are equal, since they are opposite sides in the parallelogram FP; and MF is equal to HB. Therefore PQ and HB are also equal. Moreover they are parallel, on account of the parallelogram HDB. [Margin: b — 33.prim. (*Elements* I.33)] Consequently HP and BQ are likewise parallel and equal, and so HPQB is a parallelogram. By the same reasoning HPNA, ANOK, and KOQB are parallelograms; and NOQP is a parallelogram as well. Therefore APQR is a parallelepiped.

[Margin: c — 29.prim. (*Elements* I.29)] For this reason the parallelepiped AIDK is equal to the parallelepiped APQK, since both have the same base AB and their standing edges lie on the same straight lines CO and IQ. In the same way the

parallelepiped AMFK will be equal to that same parallelepiped APQK, since both have the same base AB and their standing edges lie on the same straight lines NM and OF. Therefore the parallelepipeds AIDK and AMFK are equal to one another. Solid parallelepipeds on the same base, and so forth. Which was to be demonstrated.

Diagram. A three-dimensional wireframe showing the compound of parallelepipeds AIDK and AMFK standing on the common base AB, with the diagonal edges CG and ID produced and the auxiliary solid APQR/APQK completed; internal diagonals are drawn on several faces. Readable vertex labels, by position:

- A (bottom-left) and K (bottom-right): the base corners
- M (top-left) and F (top-right): the upper front corners
- P (upper, right of M), D (upper-centre), Q (upper-right, below F)
- H (left flank), E (centre), B (centre, right of E), I (right flank, below Q)
- C (lower-left), N (lower-centre), G (lower-centre, right of N)
- One further interior label at the lower-right is foxed and cannot be resolved [?]; the points O and R named in the text are expected here but are not clearly legible on the leaf [?].

(interior labels foxed).

Scholium

Converse of the proposition, and of the one preceding, stated in this manner:

Equal solid parallelepipeds on the same base — whether their standing edges are set upon the same straight lines or not — are at the same height.

[Margin: d — 29.vel 30.undec. (*Elements* XI.29 or 30)] For suppose one is said to be taller. If from it a parallelepiped is cut off having the same height as the other, the part cut off and the remainder will be equal. Since, then, the whole is also supposed equal to this remainder, the part cut off will be equal to the whole. Which is absurd.

[Margin: xxxi. xxxii. (alternative proposition numbering)]

THEOR. 26. PROPOS. 31.

Solid parallelepipeds set up on equal bases and at the same height are equal to one another.

Let the parallelepipeds AEFG and CHIK be set up on the equal bases AB and CD at the same height. I say that these parallelepipeds are equal to one another.

First, let the standing edges AM, GN, LE, BF on the base AB, and the standing edges CP, KQ, OH, DI on the base CD, be perpendicular. This being so, all the said perpendiculars will be equal to one another, because of the equal height of the parallelepipeds. Produce CK in a straight line, let KR be made equal to LB, and let the angle RKS in the plane OK, when extended, be made equal to the angle BLA; let KS be put equal to LA, and let the parallelogram KT be completed. On this let the parallelepiped QSTV be constructed, with KQ perpendicular for its height.

Now since the sides KR and KS are equal to the sides LB and LA, and the angles RKS and BLA are equal, the parallelograms KT and LG will be equal and similar. Again, since the sides KQ and KS are equal to the sides LE and LA, and the angles QKS and ELA are right — by definition 3 of this book, because KQ and LE are set as perpendiculars to the planes KT and LG — the parallelograms QS and EA will also be equal and similar. In the same way, since the sides KR and KQ are equal to the sides LB and LE, and the angles QKR and ELB are right, by the same definition 3 of this book the parallelograms KV and LF will likewise be equal and similar.

[Margin: a — 24.unde. (*Elements* XI.24)] Therefore, since the three faces KT, QS, KV of the parallelepiped QSTV are equal and similar to the three faces LG, EA, LF of the parallelepiped AEFG — [Margin: b — 24.unde. (*Elements* XI.24)] and both these and those are equal and similar to the three remaining faces opposite them — the parallelepipeds QSTV and EAGF will, by definition 10 of this book, be equal to one another.

Let the straight lines DK and TS, when produced, meet at δ , and IQ and XY at ϵ , and let the parallelepiped Q δ γ V be completed. Likewise let HI and β V, when drawn out, meet at α , and OD and γ R at Z, and let the parallelepiped IKR α be completed. Now since the parallelepipeds QSTV and Q δ γ V have the same base KV and are at the same height — namely between the same parallel planes KV and δ X — and their standing edges KS, K δ , RT, R γ , QY, Q ϵ , VX, V β lie on the same straight lines δ T ϵ X, [Margin: c — 29.unde. (*Elements* XI.29)] they will be equal to one another. But the parallelepiped QSTV is equal to the parallelepiped EAGF. Therefore the parallelepiped Q δ γ V will also be equal to that same parallelepiped EAGF.

[Margin: d — 35.prim. (*Elements* I.35)] Now since the parallelograms KT and Ky are equal to one another, and KT is equal to LG, Ky will also be equal to LG — that is, to CD — since the bases LG and CD are supposed equal. [Margin: e — 7.quinti.]

(*Elements* V.7)] Therefore, as CD is to DR, so is K γ to DR. [Margin: f — 25.unde. (*Elements* XI.25)] But as the base CD is to the base DR, so is the solid CHIK to the solid KI α R, since the parallelepiped CH α R is cut by the plane IK parallel to its opposite faces CH and α R. And by the same reasoning, as K γ is to DR, so is the solid Q $\delta\gamma$ V to the solid IKR α , since the parallelepiped I $\delta\gamma\alpha$ is cut by the plane KV parallel to its opposite faces D $\alpha\delta\beta$. [Margin: g — 9.quinti. (*Elements* V.9)] Therefore the parallelepipeds CHIK and Q $\delta\gamma$ V will be equal, since they have the same ratio to the same solid IKR α — namely the ratio that the equal bases CD and K γ have to the same base DR. And since the parallelepiped Q $\delta\gamma$ V has been shown equal to the parallelepiped AEFG, the parallelepipeds AEFG and CHIK will likewise be equal. Which was the thing proposed.

Diagram. A wide three-dimensional construction spanning the text column: the parallelepiped AEFG (shown with the auxiliary lettering L, B, M, N about its faces) at the left, together with the constructed solids QSTV, Q $\delta\gamma$ V, and IKR α drawn with Greek-lettered vertices toward the right. Readable Latin labels include E, F (top left corners), L, B, M, N, A, G, and toward the right Q, S, T, V, R, X, Z; Greek-lettered vertices α , β , γ , δ , ϵ appear among the auxiliary solids. Many of the small peripheral and Greek labels are foxed and cannot be resolved individually [?][?].

(numerous foxed Latin and Greek labels).

(Text continues on the following page.)

Now let the standing edges AM, GN, LE, BF to the base AB, and CP, KQ, OH, DI to the base CD, no longer be perpendicular. [Margin: h — 11.unde. (*Elements* XI.11)] From the points E, F, M, N let the perpendiculars ER, FS, MT, NV be dropped to the plane in which the base AB lies; and likewise from the points H, I, P, Q let the perpendiculars HX, IY, PZ, Q α be dropped to the plane in which the base CD lies. Then all these perpendiculars will be equal to one another, since the heights of the said parallelepipeds are equal.

Draw the straight lines RS, SV, VT, TR; likewise draw the straight lines XY, Y α , α Z, ZX, so that the parallelepipeds ETVF and HZ α I are formed. Since these are of the same height and have their standing edges perpendicular, they will be equal to one another, as has been shown. [Margin: i — 29.vel 30.undec. (*Elements* XI.29 or 30)] But the parallelepiped ETVF is equal to the parallelepiped AEFG, since it has the same base EN with it and the same height; and the parallelepiped HZ α I is by the same reasoning equal to the parallelepiped CHIK, since it has the same base HQ with it and the same height. Therefore the parallelepipeds AEFG and CHIK are also equal to one another. The same will be shown if the standing edges of one

parallelepipeds are perpendicular to the base while those of the other are not. Hence solid parallelepipeds set up on equal bases, and so forth. Which was to be demonstrated.

Diagram. Two three-dimensional parallelepipeds standing side by side (the oblique case of the proposition), each shown with its dropped perpendiculars and internal diagonals. Left solid — readable labels: E, F (top corners), I, R, B, S (upper flank), M, N (mid), A, T, G (base). Right solid — readable labels: H, I (top corners), O, X, D, and a lowercase y/γ (upper flank), P, Q (mid), C, Z, K, α (base), R (right flank). Several small labels are foxed [?][?].

(many crowded foxed labels).

Scholium

Perhaps, following Campanus, it can be demonstrated more expeditiously that two parallelepipeds set up on equal bases and at the same height, whose standing edges are perpendicular to the bases, are equal to one another — namely from the bases alone, without the construction of parallelepipeds — though the demonstration is the same as ours. For let there be two equal bases, namely the two parallelograms AB and CD. I say that the parallelepipeds set up on them, at the same height, whose standing edges to the bases AB and CD are perpendicular, are equal to one another. Produce the two sides DE and CE toward the parts of E. Then make the angle FEG equal to the angle L; put the straight line EF equal to LB, and the straight line EG equal to LA; and let a parallelogram be completed which will be equal and similar to the parallelogram AB.

Let HG, when produced, meet DE produced at I, and let the parallelogram IK be completed. Now let there be understood, set up on the bases EH, IF, EK, parallelepipeds of the same height as the parallelepipeds constructed on AC and CD, their standing edges being perpendicular to the said bases. It is clear, then, that the solid on EH is equal and similar to the solid on AB — by definition 10 of this book — since its faces are equal and similar to the faces of that solid, by construction. [Margin: k — 29.unde. (*Elements* XI.29)] Moreover the parallelepipeds on EH and IF are equal, since they have the same base — whose lowest side is EF, erected upon the plane IK — and likewise the faces opposite the base, whose lowest sides GH and IM lie in the same plane, and their standing edges EG, FH, EI, FM, and so forth, lie on the same straight lines IH, and so forth. [Margin: l — 35.prim. (*Elements* I.35)] Therefore the parallelepiped on IF will be equal to the parallelepiped on AB. Since the parallelogram EH is equal to CD, IF and CD will be equal. [Margin: m — 7.quinti. (*Elements* V.7)] Therefore it will be

that as IF is to EK, so is CD to EK. [Margin: n — 25.unde. (*Elements* XI.25)] But as IF is to EK, so is the solid on IF to the solid on EK, since the solid on IK is cut by the plane on EF, erected parallel to the faces erected on DK and IM. And by the same reasoning, as CD is to EK, so is the solid on CD to the solid on EK, since the solid on CK is cut by the plane on DE, erected parallel to the faces erected on CN and FK. Therefore, as the solid on IF is to the solid on EK, so is the solid on CD to the solid on EK. [Margin: o — 9.quinti. (*Elements* V.9)] And accordingly the parallelepipeds on IF and CD will be equal. But it has been shown that the parallelepiped on IF is equal to the parallelepiped on AB. Therefore the parallelepipeds on AB and CD will be equal. Which was the thing proposed.

Diagram. A plane (base-level) figure of adjoining parallelograms illustrating the Campanus construction. Readable labels, by position: N (top-left), D (top-centre), K (top-right); L (far left), B (left-centre) with C just below it, E (centre), F (right-centre); A (bottom-left), G (bottom-centre), M and H (bottom-right). A small subscript letter near G is faint [?].

This proposition will also be converted, thus:

Equal solid parallelepipeds on equal bases are at the same height. And equal parallelepipeds at the same height are on equal bases, if they do not have the same base.

[Margin: p — 31.und. (*Elements* XI.31)] For if one is supposed taller than the other: if from it a parallelepiped is cut off having the same height as the other, the part cut off will be equal to the other. Since, then, the whole is supposed equal to the other, the part cut off will be equal to the whole. Which is absurd.

And if they are at the same height, and the base of one is supposed larger than that of the other: if from it a base equal to the other's is cut off, and on the base so cut off a parallelepiped of the same height is understood, we shall show in the same way that the part is equal to the whole. Which is absurd.

THEOR. 27. PROPOS. 32.

Solid parallelepipeds under the same height are to one another as their bases.

Let there be two parallelepipeds ABCD and EFGH, of the same height, on the bases AB and EF. I say that solid is to solid as base is to base. [Margin: a — 45.prim. (*Elements* I.45)] For on the straight line EK let a parallelogram IK be constructed, equal to the parallelogram AB,

[Margin: xxxiii. (alternative proposition numbering)]

(text continues on the next page)

in the angle IEK, which is made equal to the angle ENF. The parallelograms EF and IK will make up one whole parallelogram FI, as was demonstrated in Proposition 45 of Book I. If, then, the other faces of the parallelepiped EFGH are produced toward the parts of EG, and the whole is completed into one parallelepiped IFLH, [Margin: a — 31.unde. (*Elements* XI.31)] the parallelepipeds ABCD and IKLM will be equal, since they have equal bases, by construction AB and IK, and the same height, by hypothesis. [Margin: b — 7.quinti. (*Elements* V.7)] Therefore, as the solid IKLM is to the solid EFGH, so is the solid ABCD to the same solid EFGH. [Margin: c — 25.unde. (*Elements* XI.25)] But the solid IKLM is to the solid EFGH as the base IK — that is, as the base AB equal to it — is to the base EF. Therefore the solid ABCD will also be to the solid EFGH as the base AB is to the base EF. Solid parallelepipeds under the same height are therefore to one another as their bases. Which was to be demonstrated.

Diagram. Two three-dimensional parallelepipeds side by side, the left being ABCD and the right EFGH with the completed solid IKLM adjoined. Readable labels — left solid: C (top-left), B (interior), A (bottom-left), D (right), I (bottom). Right solid: L, G (top corners), K (interior), F (right), M (interior/lower), E (bottom-centre), N (bottom-right), H (right flank), I (bottom-left). One or two labels are faint [?].

Scholium

Conversely, if solid parallelepipeds are to one another as their bases, they are under the same height.

For if the height is not supposed the same: from the greater let a portion be cut off equal to the smaller, and let a plane be drawn parallel to the base. [Margin: d — 32.undec. (*Elements* XI.32)] Then, as base is to base, so will the parallelepiped be to the parallelepiped that was cut off. But so it was also to the whole. [Margin: e — 9.quinti. (*Elements* V.9)] Therefore the part cut off is equal to the whole. Which is absurd.

[Margin: xxxvi. (alternative proposition numbering)]

THEOR. 28. PROPOS. 33.

Similar solid parallelepipeds are to one another in the triplicate ratio of their corresponding edges.

Let there be similar parallelepipeds ABCD and EFGH on the similar bases AB and EF, in which the corresponding edges are AI and EK. I say that the ratio of the parallelepiped ABCD to the parallelepiped EFGH is the triplicate of the ratio of the corresponding edges AI and EK. For produce AI to L, and let IL be equal to EK, or to GR; likewise produce DI to M, and let IM be equal to HK, or to GO; likewise produce BI to N, and let IN be equal to KF, or to GS. Then, completing the parallelograms LM, LN, IT, let the parallelepiped TXIV be completed.

Now since the sides IL and IM are equal to the sides GR and GO, [Margin: a — 15.prim. (*Elements* I.15) [?]] and the contained angles are equal — for the angle LIM is equal to the angle AID, which, on account of the similarity of the parallelepipeds, is equal to the angle EKH, or RGO — the parallelograms IX and GF will be similar and equal. By the same reasoning LN and RS will be similar and equal, and likewise IT and GE. Therefore the three faces IX, LN, IT of the parallelepiped TXIV are similar and equal to the three faces GF, RS, GE of the parallelepiped EFGH. [Margin: b — 24.unde. (*Elements* XI.24)] But the three faces of each are similar and equal to the three remaining faces opposite them. Therefore the parallelepipeds TXIV and EFGH are equal and similar, by definition 10 of this book.

Again, completing the parallelograms MB, BL, LM, let the parallelepiped MPBL be completed; likewise, completing the parallelograms IY, DL, IQ, let the parallelepiped IYQZ be completed. Now since, on account of the similarity of the parallelepipeds ABCD and EFGH, as AI is to EK — that is, to IL — so is DI to HK, that is, to IM; and BI to FK, that is, to IN: [Margin: c — 1.sexti. (*Elements* VI.1)] and as AI is to IL, so is the parallelogram AD to DL; and as DI is to IM, so is the parallelogram DL to LM; and as BI is to IN, so is the parallelogram BL to LN. Therefore it will be that as AD is to DL, so is DL to LM, and BL to LN. [Margin: d — 32.unde. (*Elements* XI.32)] But as the base AD is to the base DL, so is the parallelepiped ADCB to the parallelepiped DLYQ; and as the base DL is to the base LM, so is the parallelepiped DLYQ to the parallelepiped LMBP; and as the base BL is to the base LN, so is the parallelepiped LMBP to the parallelepiped LNTX. Therefore it will be that as the parallelepiped ADCB is to the parallelepiped DLYQ, so is the parallelepiped DLYQ to the parallelepiped LMBP, and the parallelepiped LMBP to the parallelepiped LNTX.

And accordingly the four magnitudes ADCB, DLYQ, LMBP, LNTX are continuously proportional; and therefore the ratio of the first, ADCB, to the fourth, LNTX — that is, to EFGH — will be the triplicate of the ratio of the first, ADCB, to the second, DLYQ, by definition 10 of Book V. [Margin: e — 32.und. (*Elements* XI.32)]

But as ADCB is to DLYQ, so is the base AD to the base DL; [Margin: f — 1.sexti. (*Elements* VI.1)] and as AD is to DL, so is the straight line AI to IL, that is, to EK. Therefore the ratio of the parallelepiped ADCB to the parallelepiped EFGH is the triplicate of the ratio of the corresponding edges, namely of AI to EK. Wherefore similar solid parallelepipeds are to one another in the triplicate ratio of their corresponding edges. Which was to be demonstrated.

Diagram. A large compound three-dimensional construction: the parallelepiped ABCD (upper solid) with the completed solids TXIV, DLYQ, LMBP, LNTX, IYQZ, MPBL, and the smaller solid EFGH (lower-left) drawn together. Readable labels — upper region: C, Q (top), B, P, D, Z, A, R, I, L, M, X, N, T, V; lower-left solid: G, O, F, S, H, E, K. The construction carries roughly twenty-two lettered vertices; several interior labels are foxed and cannot each be resolved with certainty [?][?].

(very many crowded/foxed labels).

Corollary

From this it is evident that if four straight lines are continuously proportional, then the parallelepiped described on the first is to the parallelepiped similar and similarly described on the second as the first line is to the fourth. For both the parallelepiped to the parallelepiped, as has been demonstrated, and the first line to the fourth, by definition 10 of Book V, have the triplicate ratio of the ratio of the first line to the second — namely of the corresponding edges.

THEOR. 29. PROPOS. 34.

[Margin: xxxiv. / xxxv. — the corresponding proposition numbers in the vulgate (Theon) Euclid; Clavius's Prop. 34 answers to *Elements* XI.34 and 35.]

In equal parallelepiped solids the bases and heights are reciprocally proportional; and those parallelepiped solids whose bases and heights are reciprocally proportional are equal.

(*Clavius's demonstration.*)

Let ADCB, EHGF be equal parallelepipeds on the bases AD, EH. I say that the bases AD, EH and the heights of the parallelepipeds ADCB, EHGF are reciprocally proportional — that is, as AD is to EH, so is the height of the solid EHGF to the height of ADCB.

First, let the standing lines AI, EK be perpendicular to the bases AD, EH, so that (by Elem. VI def. 4) AI, EK are the heights of the parallelepipeds. Then if the

heights AI, EK are equal — since the parallelepipeds are also assumed equal — the bases AD, EH will likewise be equal, by what we showed at the end of Prop. 31 of this book. Therefore, as the base AD is to the base EH, so will the height EK be to the height AI; and accordingly the bases and heights are reciprocally proportional.

But if the heights AI, EK are unequal, let EK be the greater; from it cut off EL equal to AI, and through L draw the plane LM parallel to the base EH (by the scholium to Prop. 15 of this book). Since, then, the solids ADCB, EHGF are equal, [Margin: a. "7. quint." — Elem. V.7] it follows that as ADCB is to the solid EHML, so is EHGF to the same solid EHML. [Margin: b. "32. undec." — Elem. XI.32] But as the solid ADCB is to the solid EHML, so is the base AD to the base EH, since the heights AI, EL are assumed equal; and as the solid EHGF is to the solid EHML, so, by the same ratio, is the base KM [recte: KN?] to the base LN, since by this ratio the solids EHGF, EHML have the same height — that is, if the bases be taken as KN, LN, for they lie between the same parallel planes KN, GH. Therefore, as the base AD is to the base EH, so is the base KN to the base LN. [Margin: c. "1. sexti" — Elem. VI.1] But as KN is to LN, so is the straight line EK to the straight line EL — that is, to AI, which is equal to EL. Therefore, as the base AD is to the base EH, so is the height EK to the height AI; and accordingly the bases and heights are reciprocally proportional.

Now let the bases and heights be reciprocally proportional. I say the parallelepipeds are equal. For if the heights EK, AI are equal — since, by hypothesis, the base AD is to the base EH as the height EK is to the height AI — the bases AD, EH will also be equal. [Margin: d. "31. unde." — Elem. XI.31] Therefore the parallelepipeds ADCB, EHGF, having equal bases and the same height, will be equal to one another.

But if the height EK be the greater, cut off EL equal to AI, and through L draw the plane LM parallel to the base EH. Since, then, by hypothesis, as the base AD is to the base EH, so is the height EK to the height AI — that is, to EL, which is equal to AI — [Margin: e. "32. unde." — Elem. XI.32] and since, as the base AD is to the base EH, so is the solid ADCB to the solid EHML (the heights AI, EL being assumed equal); [Margin: f. "1. sexti" — Elem. VI.1] and as EK is to EL, so is KN to LN; [Margin: g. "32. unde." — Elem. XI.32] and as the base KN is to the base LN, so is the solid EHGF to the solid EHML (since the solids EHGF, EHML have the same height, if the bases be taken as KN, LN, for by this reasoning they lie between the parallel planes KN, GH) — it will follow that, as the solid ADCB is to the solid

EHML, so is the solid EHGF to the same solid EHML. [Margin: h. "9. quin." — Elem. V.9] And therefore the solids ADCB, EHGF are equal.

But now let there be proposed equal parallelepipeds ABCD, EFGH whose standing lines AI, KD, BM, LC and EN, OH, FQ, PG are not perpendicular to the bases AB, EF. From the points I, D, M, C let perpendiculars IR, DS, MV, CT be dropped to the plane of the base AB; likewise from the points N, H, Q, G let perpendiculars NX, HY, Q α , GZ be dropped to the plane of the base EF; and let the straight lines RS, TV, AT, SV and XY, Z α , XZ, Y α be joined. Then, by Elem. VI def. 4, the perpendiculars RI, XN will be the heights of the parallelepipeds. I say again that, as the base AB is to the base EF, so is the height XN to the height RI. [Margin: i. "29. vel 30. undec." — Elem. XI.29 or 30] For since the solids ABCD, EFGH are equal by hypothesis, [Margin: k. "24. und." — Elem. XI.24] and ABCD is equal to the solid RVCD (because they have the same base CD and the same height RI), and EFGH, by the same reasoning, is equal to the solid X α GH: the parallelepipeds RVCD, X α GH will also be equal. Therefore, since they have standing lines perpendicular to the bases CD, GH, it will follow — as already demonstrated — that as the base CD is to the base GH (that is, as the base AB is to the base EF), so is the height XN to the height RI. And accordingly the bases and heights are reciprocally proportional.

Now let the bases and heights be reciprocally proportional. I say the parallelepipeds are equal. For, with the figure constructed as before: since, as the base AB is to the base EF, so is the height XN to the height RI; [Margin: l. "24. vnd." — Elem. XI.24] and since AB is equal to CD, and EF to GH — it will also follow that, as the base CD of the solid RVCD is to the base GH of the solid X α GH, so is the height XN to the height RI. Therefore, since XN, RI are the standing lines perpendicular to the bases CD, GH, the parallelepipeds RVCD, X α GH will be equal, as already shown. [Margin: m. "29. vel 30. vnd." — Elem. XI.29 or 30] But these parallelepipeds are equal to the parallelepipeds ABCD, EFGH. Therefore the parallelepipeds ABCD, EFGH will also be equal. The same will be shown if the standing lines of one parallelepiped are perpendicular to its base, but those of the other are not. For this reason, the bases and heights of equal parallelepiped solids are reciprocally proportional, and so on. Which was to be shown.

Diagram. Two upright rectangular parallelepipeds of equal height, illustrating the first case of the proof (equal heights).

- Left solid (ADCB): C (top back-left), I (upper front-left, on the vertical edge), B (upper front-right, interior), A (bottom front-left), D (bottom front-right).

- Right solid (EHGF): G (top back), K (upper front-left), F (upper front-right), E (bottom front-left), H (bottom front-right).

Diagram. The case of unequal heights: a shorter box ADCB and a taller box EHGF cut by the plane LM at the height EL (= AI), forming the sub-solid EHML.

- Left solid (ADCB): C (top), B (upper-right, interior), A (bottom-left), D (bottom-right).
- Right solid (EHGF, with cutting plane): G (top back), K (upper front-left), M (mid, right edge, at the cut), L (mid, left interior, at the cut), I (left edge, lower), E (bottom front-left), N (bottom, mid), H (bottom front-right). F (upper front-right of EHGF) not clearly legible under the foxing [?].

Diagram. Two oblique (slanting) parallelepipeds ABCD and EFGH with perpendiculars dropped to the base planes and the auxiliary right parallelepipeds RVCD and $X\alpha GH$ constructed; heavily foxed and crowded with construction lines.

- Left figure (ABCD / RVCD): C (top-left), L (top-mid), M (top-right), B (right), T (upper-left), V (interior), I (left-lower, interior), D (lower-mid), R (bottom-left), A (bottom-mid), S (bottom-right).
- Right figure (EFGH / $X\alpha GH$): U (top-left) [?], Q (top-mid), Z (upper-left), α (interior, printed as an "oc"-like ligature), F (upper-right), N (bottom-left), H (bottom-mid), K (bottom, left of centre), E (bottom) [?], Y (bottom, adjoining E) [?], O (bottom-right). Vertex G of EFGH not separately legible [?].

SCHOLIUM

All that has been demonstrated in the six preceding propositions — namely 29, 30, 31, 32, 33, and 34 — applies also to prisms which have two opposite triangular faces, provided the aforesaid hypotheses are maintained. For if to two such prisms of the same height, set upon the same base or upon equal bases, two other prisms equal and similar to them be added, two parallelepipeds of the same height will be produced, standing upon the same or upon equal bases. [Margin: m. "29. 30. vel 31. undec." — Elem. XI.29, 30, or 31] Therefore such parallelepipeds will be equal; and consequently so too will the given prisms, being namely their halves.

Again, if to two of the aforesaid prisms of the same height, set upon different bases, two other prisms equal and similar to them be adjoined, two parallelepipeds will again be produced, so that parallelepiped is to parallelepiped as base to base. [Margin: n. "32. und." — Elem. XI.32] Therefore parallelepiped will be to parallelepiped as base to base; [Margin: o. "15. quin." — Elem. V.15] and

so prism will be to prism — namely the half of one parallelepiped to the half of the other — as base to base, if the bases of the prisms be parallelograms; or else triangle to triangle, that is, the half of one base to the half of the other, if the bases of the prisms be triangles.

Moreover, if to the two aforesaid similar prisms two other prisms equal and similar to them be added, two similar parallelepipeds will be constituted, [Margin: p. "33. unde." — Elem. XI.33] which have to one another the triplicate ratio of the corresponding sides. Therefore the prisms too — namely their halves — [Margin: q. "15. quint." — Elem. V.15] since they have the same ratio as the parallelepipeds, will have the triplicate ratio of those same corresponding sides, which are likewise the corresponding sides of the prisms.

Finally, if to the said two equal prisms two other prisms equal and similar to them be adjoined, two equal parallelepipeds of the same heights as the prisms will be composed. [Margin: r. "34. vnd." — Elem. XI.34] Therefore, since the bases and heights of the parallelepipeds are reciprocally proportional, and the bases of the prisms are the same — or at least their halving triangles [Margin: s. "15. quinti." — Elem. V.15] have the same ratio — the bases of the prisms and their heights will also be reciprocally proportional.

THEOR. 30. PROPOS. 35.

[Margin: xxxvii. — vulgate Euclid proposition number (= XI.37).]

If two plane angles are equal, and upon their vertices stand elevated straight lines which contain equal angles with the lines first placed (each with each); and if on the elevated lines any points be taken, and from these perpendiculars be drawn to the planes in which the angles first placed lie; and if from the points which arise in the planes from those perpendiculars straight lines be joined to the angles first placed: then these joining lines, together with the elevated lines, contain equal angles.

(Clavius's demonstration.)

Let BAC, EDF be two equal plane angles, upon whose vertices A and D there stand — outside their planes — the elevated straight lines AG, DH, such that the angle BAG is equal to the angle EDH, and the angle CAG to the angle FDH. From points G, H taken on the lines AG, DH let perpendiculars GI, HK be dropped to the planes in which the angles BAC, EDF lie, meeting them at the points I, K; and let the straight lines IA, KD be joined. I say that the angles GAI, HDK are equal to one another.

For if AG, DH are unequal, from the greater AG cut off AL equal to DH, and from L, in the plane of the triangle AGI, draw LM parallel to GI. Since, then, GI, LM are parallel, and GI is perpendicular to the plane of the angle BAC, [Margin: a. "8. unde." — Elem. XI.8] LM too will be perpendicular to the same plane. From the points M, K let perpendiculars MB, MC, KE, KF [printed "KE, KE"; recte KF] be drawn to the straight lines AB, AC, DE, DF; and let the straight lines BC, BL, LC, EF, EH, HF be joined. And since LM is perpendicular to the plane of the angle BAC, it makes a right angle with the straight line AM drawn in the same plane, by def. 3 of this book. [Margin: b. "47. pri." — Elem. I.47] Therefore the square on AL will be equal to the squares on AM, ML. [Margin: c. "47. prim." — Elem. I.47] But the square on AM is equal to the squares on AC, CM, since the angle ACM is right by construction. Therefore the square on AL is equal to the squares on AC, CM, ML. [Margin: d. "47. prim." — Elem. I.47] But the squares on CM, ML are equal to the square on CL, since the angle CML is right, by def. 3 of this book. Therefore the square on AL is equal to the squares on AC, CL; [Margin: e. "48. prim." — Elem. I.48] and accordingly the angle ACL will be right. [Margin: f. "47. prim." — Elem. I.47] Again, since the square on AL is equal to the squares on AM, ML, [Margin: g. "47. prim." — Elem. I.47] and the square on AM is equal to the squares on AB, BM (since the angle ABM is right by construction), the square on AL is equal to the squares on AB, BM, ML. [Margin: h. "47. prim." — Elem. I.47] But the squares on BM, ML are equal to the square on BL, since the angle BML is right, by def. 3 of this book. Therefore the square on AL is equal to the squares on AB, BL; [Margin: i. "48. prim." — Elem. I.48] and consequently the angle ABL will be right.

The right angles DFH, DEH will be shown in no other way [i.e., by the same reasoning]. Since, then, the angles ABL, LAB of the triangle ABL are equal to the angles DEH, HDE of the triangle DEH, and the sides AL, DH are equal, [Margin: k. "26. prim." — Elem. I.26] the remaining sides AB, BL will also be equal to the remaining sides DE, EH. By the same argument the straight lines AC, CL will be equal to DF, FH. Therefore, since the sides AB, AC of the triangle ABC are equal to the sides DE, DF of the triangle DEF, and the contained angles BAC, EDF are equal by hypothesis, [Margin: l. "4. primi" — Elem. I.4] the bases BC, EF will be equal to one another, and the angles ABC, ACB equal to the angles DEF, DFE. But the whole angles ABM, ACM are equal to the whole angles DEK, DFK, since all are right; therefore the remaining angles MBC, MCB will be equal to the remaining angles KEF, KFE. And accordingly, since the sides BC, EF have also been shown equal, [Margin: m. "26. prim." — Elem. I.26] the sides BM, CM will be equal to the sides EK, FK. Since, then, the sides AC, CM of the triangle ACM have been shown equal to the sides DF, FK of the triangle DFK, and the angles ACM, DFK are right, [Margin: n. "4. prim." — Elem. I.4] the bases AM, DK will be equal to one another.

And since the straight lines BL, EH have been shown equal, their squares too will be equal. [Margin: o. "47. prim." — Elem. I.47] But since the square on BL is equal to the squares on BM, ML, and the square on EH to the squares on EK, KH — because the angles BML, EKH are right, by def. 3 of this book — the squares on BM, ML will be equal to the squares on EK, KH.

Diagram. The two configurations for Prop. 35: a pair of figures (left about the angle BAC with the elevated line AG, right about EDF with DH), each crowded with the connecting lines BC, BL, LC, EF, EH, HF and the perpendiculars.

- Left figure: A (apex, top), B (upper-left), C (right, at mid-height), L (lower-left), M (lower, mid-right), G (bottom-left), I (bottom, mid-right).
- Right figure: D (apex, top), E (upper-left), F (right), H (lower-left), K (lower, mid).

LIBER XI. (*continuation of Prop. 35*)

the squares on EK, KH. Therefore, when the squares on BM, EK are taken away — which are equal, since the lines BM, EK have been shown equal — the remaining squares on LM, HK will be equal; and accordingly the lines LM, HK are equal. For this reason, since the sides AL, AM of the triangle ALM are equal to the sides DH, DK of the triangle DHK, and the base LM is equal to the base HK, [Margin: p. "8. primi" — Elem. I.8] the angles LAM, HDK will also be equal. Therefore, if two plane angles are equal, upon whose vertices stand elevated straight lines, and so on. Which was to be shown.

Diagram. The Prop. 35 figure repeated at the head of the page (as Clavius customarily repeats a figure carried over the page break); the same pair of angle-and-elevated-line constructions with their connecting lines.

- Left figure: A (apex), B (upper-left), C (right, mid-height), L (lower-left), M (lower-right), G (bottom-left), I (bottom-right).
- Right figure: D (apex), E (upper-left), F (right), H (lower-left), K (lower, mid).

COROLLARIVM

Therefore, if two plane angles are equal, upon whose vertices stand *equal* elevated straight lines which contain equal angles with the lines first placed (each with each): then the perpendiculars dropped from the extreme points of the elevated lines to the plane of the angles first placed will be equal to one another. For, because the plane angles BAC, EDF are assumed equal, and the equal

elevated lines AL, DH form equal angles DAB, HDE — and likewise LAC, HDF — it was demonstrated that the dropped perpendiculars LM, HK are equal.

THEOR. 31. PROPOS. 36.

[Margin: xxxviii. — vulgate Euclid proposition number (= XI.38).]

If three straight lines be proportional, then the parallelepiped solid formed from these three is equal to the parallelepiped solid described on the mean line — a solid which is indeed equilateral, but equiangular to the aforesaid one.

(Clavius's demonstration.)

Let A, B, C be continuously proportional straight lines. Construct a solid angle E out of any three plane angles DEF, DEG, FEG, such that the straight line DE is equal to A, EF to B, and EG to C. Completing the parallelograms DF, FG, GD, complete the parallelepiped DH, which is said to be contained under the three lines A, B, C, or to be made from them. [Margin: a. "26. vnde." — Elem. XI.26] Then, on the straight line IK and at its point K, make a solid angle K equal to the solid angle E, out of three plane angles IKL, IKM, LKM equal to the three DEF, DEG, FEG, so that the lines IK, KL, KM are equal to the mean line B. Completing the parallelograms IL, LM, MI, complete the parallelepiped IN, which is said to be contained under the line B, [and] to be described from it. I say that the solid DH is equal to the solid IN.

For since, as DE is to IK, so is KM to EG (because DE has been taken equal to A; IK, KM to B; and EG to C), and the angles DEG, IKM are equal [printed "æquales B"; the stray "B" appears to be a compositor slip — the sense requires "equal to one another"], [Margin: b. "14. sexti" — Elem. VI.14] the parallelograms DG, IM will be equal, because they have their sides about the equal angles reciprocally proportional. And since the plane angles DEG, IKM are equal, upon whose vertices stand the elevated lines EF, KL — which, by construction, contain equal angles with the lines first placed (each with each) — the perpendiculars dropped from F, L to the planes of the bases DG, IM (namely the heights of the parallelepipeds DH, IN, if the bases be taken as DG, IM) will be equal to one another, by the corollary to the preceding proposition. [Margin: c. "31. und." — Elem. XI.31] Therefore the parallelepipeds DH, IN, since they have equal bases DG, IM and equal heights as well, will be equal to one another. Therefore, if three straight lines be proportional, and so on. Which was to be demonstrated.

Diagram. The Prop. 36 figure: at the far left the three proportional lines drawn as vertical segments; then the parallelepiped DH (built on A, B, C) and the equilateral parallelepiped IN (built on the mean B).

- Three proportional lines at left: A (shortest), B (mean), C (longest), bracketed together near the labels C and F.
- Left solid (DH): H (top), G (interior), F (mid, near the lines), E (bottom, mid), D (bottom-right).
- Right solid (IN): N (top), M (interior), L (left, mid), K (bottom, mid), I (bottom-right), D (bottom-left).

SCHOLIVM

Conversely also, if a parallelepiped described from three straight lines be equal to a parallelepiped equiangular to it, described from the mean line: then the three straight lines will be continuously proportional. For let the parallelepiped DH, described from the straight lines A, B, C as was said, be equal to the parallelepiped IN equiangular to it, described from the mean B. I say that the three lines A, B, C are continuously proportional. For, as before, their heights dropped from F, L will be shown to be equal. Therefore, since these solids too are assumed equal, their bases DG, IM will be equal, by what we demonstrated at the end of Prop. 31 of this book. And since these bases have equal angles DEG, IKM by construction, [Margin: d. "14. sexti" — Elem. VI.14] they will have their sides about those equal angles reciprocally proportional — that is, as DE is to IK, so is KM to EG. Therefore, since DE has been taken equal to A; IK, KM to B; and EG to C: it will also follow that, as A is to B, so is B to C. Which was the thing proposed.

THEOR. 32. PROPOS. 37.

[Margin: xxxix. — vulgate Euclid proposition number (= XI.39).]

If four straight lines be proportional, then the parallelepiped solids which are described upon them — similar and in like manner — will be proportional. And if the parallelepiped solids, which are similar and in like manner described, be proportional, then the straight lines themselves will also be proportional.

Euclid, *Elements* Book XI (Clavius's commentary)

— Propositions 37–39

(The enunciation of Proposition 37, with its catchword SINT*, closed the previous opening; its demonstration begins here.)*

THEOR. 32. PROPOS. 37. [Margin: xxxix. = XI.39 vulgate]

If four straight lines be proportional, then the similar and similarly described parallelepipeds upon them will be proportional; and if the similar and similarly described parallelepipeds be proportional, the lines themselves will be proportional.

Let there be four proportional straight lines A, B, C, [D] — such that A is to B as C is to D — and on A and B let two similar and similarly described parallelepipeds A and B be set up; likewise on C and D two others, C and D, similar and similarly placed, whether or not these are similar to the first pair. I say that the solids A, B, C, D are also proportional — namely, that solid A is to solid B as solid C is to solid D. For, by the scholium to Proposition 11 of Book 6, let two other lines E, F be found in continued proportion to the two lines A, B, and likewise two others, G, H, to C, D. Then, since there are four lines A, B, E, F and four others C, D, G, H, taken two by two in the same ratio, *ex aequali* A will be to F as C is to H. But as A is to F, so is solid A to solid B, and as C is to H, so is solid C to solid D, by the corollary to Proposition 33 of this book. Therefore solid A is to solid B as solid C is to solid D. Which is what was proposed.

Now, conversely, let the solids A, B, C, D be proportional. I say that the lines A, B, C, D are also proportional. For, to the three lines A, B, C let a fourth proportional I be found [Margin: a = Elements VI.12], and on it let a parallelepiped be described similar and similarly placed to D, or to C [Margin: b = Elements XI.27]. Then, since recta A is to recta B as recta C is to recta I, it follows — as has just been shown — that solid A is to solid B as solid C is to solid I. But solid A is to solid B as solid C is (by hypothesis) to solid D; therefore solid C is to solid I as the same solid C is to solid D. And consequently the solids I and D are equal [Margin: c = Elements V.9]. Since these are similar and similarly described, they are contained by equal planes (by definition 10 of this book); but equal and similar planes have their corresponding sides equal (by the lemma to Proposition 22 of Book 6). Therefore the lines I and D are equal. Hence C is to I as the same C is to D; but C was set to I as recta A is to B; therefore A is to B as C is to D. And so, if four straight lines be proportional, and so forth. Which was to be demonstrated.

This whole proposition will be demonstrated more briefly with Theon, in this way. First, let A be to B as C is to D. I say that also solid A is to solid B as solid C is to solid D [Margin: d = Elements XI.33]. For since the ratio of solid A to solid B is the triplicate of the ratio of recta A to B, and likewise the ratio of solid C to solid D is the triplicate of the ratio of recta C to D, the ratios of solid A to solid B and of solid C to solid D will be equal, seeing that they are triplicates of equal ratios — namely of A to B and of C to D. This is the first part. Again, secondly, let solid A be to solid B as solid C is to solid D. I say that also A is to B as C is to D [Margin: e = Elements XI.33]. For since the ratio of solid A to solid B is the triplicate of the ratio of recta A to B, and likewise the ratio of solid C to solid D the triplicate of the ratio of recta C to D, the ratios of A to B and of C to D will be equal, since their triplicates — namely solid A to solid B and solid C to solid D — are assumed equal. This is the second part.

Diagram. A set of five parallelepiped solids and four straight-line segments illustrating the four proportional lines and the similar solids described upon them.

- A (upper left): larger parallelepiped, labelled A
- B (upper right): smaller parallelepiped, labelled B
- F, E, H, G (right, below B): four short straight-line segments with end-bars, stacked in this order — the continued-proportional lines
- C (middle left): parallelepiped, labelled C
- D (middle right): parallelepiped, labelled D
- I (lower center): parallelepiped, labelled I

SCHOLIVM.

In the same way, if there be three proportional lines, then also the similar and similarly described parallelepipeds upon them will be proportional, and so on. For if the mean line and its solid be taken twice over, there will be four proportional lines, and therefore four proportional solids, as has been demonstrated. Since, then, the solid of the second line is equal to the solid of the third line, and the second line equal to the third line, what is proposed is evident.

This whole proposition holds also for prisms whose two opposite faces are triangles, as Campanus states. For, adding prisms that are severally equal one to another, parallelepipeds arise which — as has here been demonstrated — will be proportional. Since, then, the prisms are the halves of these parallelepipeds, and have the same ratio to them [Margin: f = Elements V.15], what is proposed is evident.

THEOR. 33. PROPOS. 38. [Margin: XL. = 40]

If a plane be perpendicular to a plane, and from some point in one of the planes a perpendicular be drawn to the other plane, the perpendicular so drawn will fall on the common section of the planes.

For let plane AB be perpendicular to plane AC, and let their common section be the straight line AD; and from E, a point of plane AB, let a perpendicular be dropped to plane AC. I say that it falls on the common section AD. For, if it be possible, let it fall outside, at the point F; and from F, in plane AC, let a perpendicular FG be drawn to the line AD [Margin: a = Elements I.12], and let the straight line EG be joined in plane AB. Now since FG is perpendicular to the common section AD, it will also be perpendicular to plane AB, by definition 4 of this book, and hence also to the line GE, by definition 3 of this book. But EF is likewise perpendicular to FG, by the same definition 3. Therefore in triangle EFG the two angles EFG and EGF are right — which is absurd, since they are less than two right angles [Margin: b = Elements I.17]. Therefore the perpendicular dropped from E to plane AC does not fall outside the common section AD; and so it must fall upon it. And therefore, if a plane be perpendicular to a plane, and so forth. Which was to be demonstrated.

SCHOLIVM.

This is Theon's demonstration. We, however, shall demonstrate the same more briefly, in this way. If from the point E, given in plane AC [recte: AB — required by the construction], a perpendicular dropped to plane AC does not fall on the common section AD, but on a point F outside the section, let a perpendicular EG be drawn from E to the line AD [Margin: c = Elements I.12]; this, by definition 4 of this book, will be perpendicular to plane AC. Then from the point E, outside plane AC, two perpendiculars EF and FG [recte: EG] would have been drawn to the plane AC itself — which is impossible, as we demonstrated in the scholium to Proposition 13 of this book.

Diagram. The figure for Proposition 38: a parallelogram representing the two planes and their common section, with the point E and the two perpendiculars.

- A (left vertex): corner of the plane
- B (upper right): corner
- D (right, mid-height): point on the common section AD
- C (lower right): corner
- E (upper interior): the given point, above the section line

- G (center, on line AD): foot of the perpendicular EG on the section
- F (lower interior): the assumed foot of the perpendicular below the section; EF and FG drawn

THEOR. 34. PROPOS. 39. [Margin: XXXX = 40]

If the sides of the opposite faces of a parallelepiped solid be bisected, and planes be extended through the points of section, then the common section of these planes and the diameter of the parallelepiped solid will bisect one another.

Let AC, BD be the opposite faces of the parallelepiped AB, all of whose edges are bisected at the points I, K, L, M, N, O, P, Q; and through these let two planes IN, KO be extended, whose common section is the straight line RS. Let the diameter AB also be drawn. I say that the straight line RS and the diameter AB bisect one another.

For, joining the straight lines RB, RD, SA, SC, consider the two triangles AQS and COS. Since the sides AQ, QS of triangle AQS are equal to the sides CO, OS of triangle COS — for AQ, CO are halves of the equal lines AG, CH [Margin: a = Elements I.34], and QS, OS are equal to the two equal lines AN, HN, since AS and HS are parallelograms — and since angle AQS is equal to the alternate angle COS [Margin: b = Elements I.29]: the bases AS, CS will also be equal, and the angles ASQ, CSO equal [Margin: c = Elements I.4]. But the angles ASQ, ASO are equal to two right angles [Margin: d = Elements I.13]. Therefore CSO, ASO are also equal to two right angles; and consequently AS, CS form one straight line [Margin: e = Elements I.14]. In the same way BR, DR are shown to be equal, and one straight line to be composed of them. Again, since each of AD, BC is parallel and equal to the line FH — because AF, FC are parallelograms [Margin: f = Elements XI.9] — they are also parallel and equal to one another. Therefore the lines AC, BD joining their extremities are likewise parallel and equal [Margin: g = Elements I.33]; and so their halves AS, BR are equal. Hence the lines AB, RS lie in one and the same plane with them [Margin: h = Elements XI.7], and therefore bisect one another, namely at the point T [Margin: i = Elements I.29 & I.15]. And since the two angles AST, ATS of triangle AST are equal to the two angles BRT, BTR of triangle BRT, and side AS equal to side BR, the remaining sides TA, TS will be equal to the remaining sides TB, TR [Margin: k = Elements I.26]; and therefore AB, RS bisect one another at T. Therefore, if the sides of the opposite faces of a parallelepiped solid, and so forth. Which was to be shown.

Diagram. The figure for Proposition 39: a large parallelepiped drawn in oblique projection, with its edge-midpoints, the two section planes, their common section RS, and the diameter AB running from the lower-right to the upper-left corner. The interior is densely ruled and heavily foxed; several interior labels could not be resolved with certainty.

- B (upper-left corner)
- E (upper-right corner)
- M, R, K (upper band, left to right — R near the center-top)
- F, L, D (middle band, left to right)
- S (lower-center interior, on the section)
- H (lower-left corner), N (bottom-middle), A (lower-right corner; the diameter AB runs from here to B)
- Two apparent T labels (one on the top edge, one at center), together with O, P, Q in the lower-left/lower area, are foxed and uncertain [?] [?] [?]

COROLLARIVM.

Hence it follows that in every parallelepiped all the diameters bisect one another at a single point — namely at the point T, at which, as has here been shown, they bisect the line RS.

SCHOLIVM.

To this theorem may be added another not unlike the one we demonstrated at Proposition 34 of Book 1, namely:

If a parallelepiped solid be cut by a plane through its center, the solid will be bisected by that plane. And if a parallelepiped solid be cut in half by a plane, that plane will pass through the center.

Let the parallelepiped AB be cut by the plane CD through the center — that is, through the midpoint G of the diameter AB. I say the parallelepiped is bisected. First, let the plane CD be parallel to the opposite faces AE, BF. Since the parallel planes BF, DC, EA cut any straight lines proportionally [Margin: l = Elements XI.17], and BA is bisected at G, the sides AH, BI of the opposite faces will also be cut, and hence the bases AH, BI, in half. Then, since as base KC is to base CH, so is solid AD to solid CB [Margin: m = Elements XI.25], the parallelepiped AB is bisected by the plane CD drawn through the center G.

Diagram. The first case of the scholium to Proposition 39: a parallelepiped cut by a plane parallel to two opposite faces, with the diagonal from B to A through the center G.

- B (upper-left), D (top-middle), E (upper-right)
- I (right, upper)
- G (center, on the diagonal BA)
- H (left), K (center-right)
- F (lower-left), C (bottom-middle), A (lower-right)

(Book XI continues; the scholium to Proposition 39 runs on.)

Next, let the cutting plane pass through AI, BH, along the diameters BI, AH of the opposite faces; for in this way too the parallelepiped is cut through the center G — indeed through the whole diameter AB [Margin: n = Elements XI.7], since AB lies in the plane of the parallels AH, BI. And it was demonstrated earlier [Margin: o = Elements XI.28] that a parallelepiped is bisected by a plane drawn through the diameters of opposite faces.

Third, let the cutting plane AKBM be neither parallel to the opposite faces nor drawn through the diameters of the opposite faces, but only through the vertices A and B of the faces AH, BI. Since, then, the parallel planes AH, BI are cut by the plane AKBM, the common sections AM, BK will be parallel [Margin: p = Elements XI.18]; and similarly AK, BM will be parallel, being the common sections of the parallel planes AL, BN made by the plane AKBM. Therefore AKBM is a parallelogram [Margin: q = Elements I.34]; and hence both AK, BM and AM, BK are equal to one another. Now since the sides BK, BL of triangle BKL are equal to the sides AM, AN of triangle AMN, and angle KBL equal to angle MAN — for, producing NA, MA to O, P, the lines AO, AP will be parallel to BL, BK [Margin: r = Elements XI.10], and consequently the angles OAP, LBK will be equal [Margin: s = Elements I.15]; and since OAP is equal to angle MAN, the angles KBL, MAN will also be equal — the bases KL, MN will be equal to one another [Margin: t = Elements I.4], and the angles BKL, BLK equal to the angles AMN, ANM, and triangle equal to triangle. Therefore triangles BKL, AMN are also similar [Margin: u = Elements VI.4], since their sides about equal angles are proportional.

And since KL equals MN, angle BKL equals angle AMN, and angle KBL equals angle MAN, as we have shown, the remaining side IK will equal the remaining HM; the remaining angle BKI will equal the remaining AMH; and the remaining KBE will equal the remaining MAF. (For the whole LI equals the whole NH, and both the angles BKL, BKI and the angles AMN, AMH are equal to two right angles;

and the whole angle LBE equals the whole angle NAF, because of the similarity of the parallelograms LE, FN.) Moreover the sides BE, EI equal the sides AF, FH, and the angles BEI, EIK equal the angles AFH, FHM, because of the parallelograms LE, FN. Therefore the quadrilateral BKIE is both equilateral and equiangular with the quadrilateral AMHF, and consequently equal and similar to it, since they agree severally — sides with sides and angles with angles. In the same way the triangles BHM, AIK will be equal and similar, and the quadrilaterals AKLF, BMNE, since they are mutually equilateral and equiangular. Therefore the solid contained by the planes AKLF, FHMA, AKBM, MHB, BKL, LBHF will be equal to the solid contained by the planes BMNE, EIKB, BMAK, KIA, AMN, NAIE, by definition 10 of this book, since those planes are similar and equal to these, as has been demonstrated. Therefore the parallelepiped AB is bisected by the plane AKBM through the center G.

Diagram. A planar figure (two overlapping squares with a diagonal) accompanying the third case of the scholium.

- B (upper-right)
- I (center-left), G (center), H (center-right, just below G)
- A (lower-left)

Diagram. The third-case figure of the scholium: a parallelepiped cut by the plane AKBM through the vertices A and B. The figure is densely ruled with diagonals.

- B (upper-left), E (upper-right)
- L (left), K (center), I (right) — along the upper band
- G (center interior)
- H (mid-left), M (center), N (right)
- F (lower-left), A (bottom-center)
- O (below left), P (below right)

Finally, let the cutting plane CD be neither parallel to the opposite faces, nor drawn through the diameters of the opposite faces, nor through any of their vertices, but cut the opposite faces [AH, BI] in any way whatever. We shall show, as before, that the cutting plane CD is a parallelogram, and that both CK, DM and CM, DK are equal. In the parallelogram CD let the diameters CD, KM be drawn, and let the lines AM, BK be joined. Since, then, AF, BE are parallel to LI, because of the parallelograms AL, LE [Margin: x = Elements XI.9], they are parallel to one another; and AB, CD will lie in the same plane with them [Margin: y = Elements XI.7], and therefore bisect one another at the center G. For it is only at the center G that the line AB, by hypothesis, cuts the plane CD, in which the line CD lies. And

since angle BDC is equal to the alternate angle ACD [Margin: z = Elements I.29], and angle BGD is equal to the vertical angle AGC [Margin: a = Elements I.15], and side BG equal to side AG (because AB is bisected at the center G), side DG will also be equal to side CG [Margin: b = Elements I.26]. Since, then — by what we showed at Proposition 34 of Book 1 — the diameters CD, KM bisect one another, KM will pass through the point G, and there will cut the diameter AB. Now since the sides BG, GD of triangle BGD are equal to the sides AG, GC of triangle AGC [Margin: c = Elements I.15], and angle BGD equal to angle AGC, the base BD will be equal to the base AC [Margin: d = Elements I.4]. By the same reasoning the lines BK, AM will be equal. Therefore, since the three sides ED [recte: BD], DK, KB of triangle BDK are equal to the three sides AC, CM, MA of triangle ACM, the angles of the one will — by what we taught at Proposition 8 of Book 1 — be equal to the angles of the other. But the whole angle DBL equals the whole CAN, because of the similarity of the parallelograms BI, AH. Therefore the remaining angle KBL will be equal to the remaining MAN. Since, then, the sides BK, BL of triangle BKL are equal to the sides AM, AN of triangle AMN, and angle KBL equal to angle MAN, the base KL will equal the base MN [Margin: e = Elements I.4], and the remaining angles equal to the remaining angles. If, then, to the equal angles BKL, AMN the angles BKD, AMC be added, the whole angles DKL, CMN become equal. Therefore the quadrilateral BDKL is both equilateral and equiangular with the quadrilateral ACMN, and consequently equal and similar, since they agree severally — sides with sides and angles with angles. Again, since the whole LI equals the whole NH, the remaining IK will equal the remaining HM. And by the same reasoning the remaining DE will equal the remaining CF; and consequently the quadrilateral DEIK is equilateral with the quadrilateral CFHM — and equiangular too, since the angles DEI, EIK are equal to the angles CFH, FHM, because of the similarity of the parallelograms BI, AH, and the angles EDK, IKD equal to the angles FCM, HMC, since their alternate angles LKD, BDK have been shown equal to the angles NMC, ACM. Therefore the quadrilaterals DEIK, CFHM are equal and similar. In the same way we shall show that the quadrilaterals ACKI, BDMH are equal and similar; and likewise DENM, CFLK, since both their sides agree with sides and angles with angles, as by definition 10 of this book. Therefore the solid contained by the planes CKLF, FHMC, CKDM, MHBD, DKLB, BHFL is equal, by definition 10 of this book, to the solid contained by the planes DMNE, EIKD, DMCK, KIAC, CMNA, AIEN; since these have been demonstrated equal and similar to those. Therefore the parallelepiped AB is bisected through the center G by the plane CD.

But now let the parallelepiped AB be cut in half by the plane CD. I say that the plane CD passes through the center of the parallelepiped, [these...]

- one further label at lower-left, foxed and uncertain [?]

Elements, Book XI

(Continuation of the Scholium to Proposition 39 — the converse.)

that is, the point G, at which the plane CD cuts the diameter AB, bisects the diameter AB. For if the diameter AB is not bisected at G, let it be bisected at E, so that E is the center of the parallelepiped. Then if through E a plane FH is drawn parallel to the plane CD, the parallelepiped AB will be bisected by the plane FH, as has been demonstrated. But it is also assumed to be bisected by the plane GD. Therefore the solids CB and FB, being halves of the parallelepiped AB, are equal to one another — the part and the whole. Which is absurd. Therefore no point other than G will bisect the diameter AB; and accordingly G will be the center of the parallelepiped. Which was to be demonstrated.

Diagram. A parallelepiped (rectangular box) drawn in oblique projection, with the internal diagonals and the common sections of the bisecting planes shown crossing near the center. Labels read off the figure:

- B (top back, left corner): vertex
- D (top back, center): vertex

- E (interior, center): the center of the parallelepiped
- C (bottom front, left): vertex
- F (bottom front, center): vertex
- A (bottom front, right): vertex

THEOR. 35. PROPOS. 40.

[Margin: outer numeral xxxxj (= 41)]

If there are two prisms of equal height, one of which has a parallelogram for its base and the other a triangle, and the parallelogram is double the triangle: the prisms themselves will be equal.

Let there be two prisms of equal height, ABCDEF and GHIKLM, of which the former has the parallelogram ABCD for its base and the latter the triangle GHI; and let the parallelogram AC be double the triangle GHI. I say that these prisms are equal. For let the parallelepipeds AN and GQ be completed — which will be done if the planes of the triangles are extended and the parallelograms BN, AO and GP, MQ are completed. For if the straight lines NO and PQ are joined, two parallelepipeds AN and GQ will be constructed, of the same height as the prisms; and that the opposite planes of these solids are parallel is easily gathered from Proposition 15 of this book. [Margin: a — *Elements* I.34] Now since the parallelogram GP is double the triangle GHI, and the parallelogram AC is likewise assumed to be double the same triangle GHI, the parallelograms AC and GP will be equal. [Margin: b — *Elements* XI.31] Therefore the parallelepipeds AN and GQ, of the same height and standing on equal bases AC and GP, are equal to one another; and consequently their halves — namely the prisms ABCDEF and GHIKLM [Margin: c — *Elements* XI.32] (for the parallelepipeds AN and GQ are bisected by the diagonals CF, DE, HI, LK of their opposite planes, into two prisms each) — are likewise equal to one another. And so, if there are two prisms of equal height, and so on. Which was to be demonstrated.

Diagram. Two oblique-projection boxes (parallelepipeds), each formed by completing a prism. On the left, the parallelepiped AN built on the parallelogram-based prism ABCDEF; on the right, the parallelepiped GQ built on the triangle-based prism GHIKLM, each shown cut by a diagonal plane. Labels read off the figure:

Left box (parallelepiped AN):

- O (top, left) and N (top, right): the completing vertices
- E (front, upper left) and F (front, upper right): vertices
- D (bottom, left), C (bottom, center), A (bottom, far left), B (bottom, center-right): base vertices

Right box (parallelepiped GQ):

- L (top, left) and Q (top, right): vertices
- K (right side, upper): vertex
- H (front, lower center): vertex

- G (bottom, left) and P (bottom, right): vertices
- I (bottom front) and M (mid-left): labels foxed and not clearly resolved on the woodcut [?]

SCHOLIVM.

It is clear from the demonstration that this proposition is to be understood only of those prisms which have two triangles as their opposite faces; for it requires that the parallelepipeds be completed — which could not be done if the prism standing on the parallelogram ABCD did not have two triangles, namely ADE and BCF. For otherwise it would already be a completed parallelepiped.

FINIS ELEMENTI VNDECIMI (*End of the Eleventh Book of the Elements.*)

EUCLID'S TWELFTH BOOK OF THE ELEMENTS

and the Second Book of Solids.

THEOR. 1. PROPOS. 1.

[Margin: outer numeral I.]

Similar polygons inscribed in circles are to one another as the squares on the diameters.

Let there be two similar polygons ABCDE and FGHIK, inscribed in circles whose diameters are AL and FM. I say that the polygon ABCDE is to the polygon FGHIK as the square on the diameter AL is to the square on the diameter FM. For let the straight lines AC and FH subtend the equal angles ABC and FGH, and let the straight lines BL and GM be joined. Now since, on account of the similarity of the polygons, AB is to BC as FG is to GH, [Margin: a — *Elements* VI.6] the triangles ABC and FGH will be equiangular, since they have proportional sides about the equal angles ABC and FGH. [Margin: b — *Elements* III.21] But the angle ALB is equal to the angle ACB, and the angle FMG to the angle FHG. Therefore the angles ALB and FMG will also be equal. And since the angles ABL and FGM are likewise equal [Margin: c — *Elements* III.31] — namely, being right angles standing in semicircles — [Margin: d — *Elements* I.32] the remaining angles BAL and GFM will also be equal. [Margin: e — *Elements* VI.4] Therefore AL is to AB as FM is to FG; and, alternately, AL is to FM as AB is to FG. [Margin: f — *Elements* VI.22] Therefore the square on AL is to the square on FM as the polygon ABCDE on AB is to the polygon FGHIK on FG, since both the squares and the polygons are similar

figures and similarly described. And so, similar polygons inscribed in circles are to one another as the squares on the diameters. Which was to be demonstrated.

Diagram. Two circles, each with an inscribed pentagon and a drawn diameter. Labels read off the figure:

Left circle (polygon ABCDE, diameter AL):

- A (top), B (left), C (lower left), D (lower right), E (right): pentagon vertices
- L (bottom): the other endpoint of the diameter AL

Right circle (polygon FGHIK, diameter FM):

- F (top), G (left), H (lower left), I (lower right), K (right): pentagon vertices
- M (bottom): the other endpoint of the diameter FM

THEOR. 2. PROPOS. 2.

[Margin: outer numeral ij.]

Circles are to one another as the squares on their diameters.

Let there be two circles ABCD and EFGH, whose diameters are AC and EG. I say that the circle ABCD is to the circle EFGH as the square on the diameter AC is to the square on the diameter EG. For if this is not so, then let the circle ABCD be to some magnitude — namely to I — as the square on the diameter AC is to the square on the diameter EG, where I will be either less or greater than the circle EFGH. For if I were equal to it, [Margin: a — *Elements* V.7] the circle ABCD would have the same ratio to the circle EFGH and to I; and therefore the circle ABCD would be to the circle EFGH as the square on the diameter AC is to the square on the diameter EG, which is not granted. Suppose, then, first that I is less than the circle EFGH, by the magnitude K — that is, so that the circle EFGH is equal to the magnitudes I and K together. Let there be inscribed...

Diagram. Two circles, each with an inscribed octagon, together with two small lens (vesica) shapes at the right labelled I and K representing the auxiliary magnitudes. Labels read off the figure:

Left circle (octagon APBQCRDS, diameter AC):

- A (top), B (left), C (bottom), D (right): the four principal points
- P (upper left), S (upper right), Q (lower left), R (lower right): the bisection points of the arcs (the lower two, Q and R, are foxed on the woodcut but are named APBQCRDS in the text)

Right circle (octagon ELFMGNHO, diameter EG):

- E (top), F (left), G (bottom), H (right): the four principal points
- L (upper left), O (upper right), M (lower left), N (lower right): the bisection points of the arcs
- T (above E) and V (near F): endpoints of the tangent line TV drawn tangent to the circle at L

Auxiliary magnitudes:

- I and K: two small lens shapes at the right

there be inscribed in the circle EFGH the square EFGH; and since this is half of the square described about the same circle — as we showed at Proposition 9 of Book 4 — it will be greater than half of the circle EFGH. Let the arcs EF, FG, GH, HE be bisected at the points L, M, N, O, and let the straight lines LE, LF, MF, MG, NG, NH, OH, OE be joined. Through L let the straight line TV be drawn tangent to the circle at L, which will be parallel to EF — as we showed at Proposition 27 of Book 3 — and let it meet the straight lines HE and GF produced at T and V. Since, then, the triangle ELF is half of the parallelogram TEFV, [Margin: b — *Elements* I.41] the triangle ELF will be greater than half of the segment ELF of the circle. By the same reasoning the remaining triangles will each be greater than half of the segments in which they lie. Therefore all the triangles together are greater than half of all the segments together. And if again the arcs EL, LF, and so on are bisected and straight lines joined, triangles will be constructed in the same way, which together will be greater than half of all the segments in which they lie; and so on in succession. Now since, if from the circle EFGH more than half is taken away — namely the square EFGH — and from the remaining segments more than half — namely the triangles ELF, FMG, and so on — and the subtraction is always carried out in this manner, [Margin: c — *Elements* X.1] there is finally left a magnitude smaller than K, the excess between the circle EFGH and the magnitude I. Now let the segments of the circle left over — EL, LF, FM, and so on — taken together be less than the magnitude K. Then, since the circle EFGH is supposed equal to the magnitudes I and K together, if from the circle the said segments are subtracted, and from I and K the magnitude K itself — which is greater than the aforesaid segments of the circle — is subtracted, the remaining polygon ELFMGNHO will be greater than the remaining magnitude I. Let there be inscribed in the circle ABCD a polygon APBQCRDS similar to the polygon ELFMGNHO. This will easily be done if the semicircles ABC and ADC are bisected at B and D, and again the arcs AB, BC, CD, DA at P, Q, R, S, and so on in succession, until the circumference ABCD is divided into as many equal parts as the

circumference EFGH is distributed into. For when the straight lines AP, PB, BQ, and so on are joined, the inscribed figure will be similar to the figure ELFMGNHO, as is evident. [Margin: d — *Elements* XII.1] Now since the polygon APBQCRDS is to the polygon ELFMGNHO as the square on the diameter AC is to the square on the diameter EH [recte: EG] — that is, by hypothesis, as the circle ABCD is to I — but the polygon APBQCRDS will be less than the circle ABCD, [Margin: e — *Elements* V.14] therefore the polygon ELFMGNHO will also be less than I. But it was shown to be also greater. Which is absurd. Therefore the magnitude I is not less than the circle EFGH.

Diagram. A repetition, at the head of the continuation page, of the Proposition 2 figure: two circles with inscribed octagons and the two lens shapes I and K. Labels read off the figure:

Left circle (octagon APBQCRDS, diameter AC):

- A (top), B (left), C (bottom), D (right): principal points
- P (upper left), S (upper right), Q (lower left, "e"-form on the woodcut [?]), R (lower right): arc-bisection points

Right circle (octagon ELFMGNHO, diameter EG):

- E (top), F (left), G (bottom), H (right): principal points
- L (upper left), O (upper right), M (lower left), N (lower right): arc-bisection points
- T (above E) and V (near F): endpoints of the tangent line TV

Auxiliary magnitudes:

- I and K: two small lens shapes at the right

Although in the figure the larger circle is compared with the smaller, we shall nevertheless demonstrate in the same way that the smaller circle EFGH cannot have to a magnitude smaller than the larger circle ABCD the same ratio that the square on the smaller diameter EG has to the square on the larger diameter AC. So that it may be demonstrated generally and universally that the square on the diameter of any circle can never have to the square on the diameter of another circle the same ratio that the former circle has to a magnitude smaller than the latter circle — whether the former circle be greater than the latter, or smaller.

Next, let the magnitude I be greater than the circle EFGH. Then, since the circle ABCD is supposed to be to I as the square on the diameter AC is to the square on the diameter EG, then also, by conversion, I will be to the circle ABCD as the

square on the diameter EG is to the square on the diameter AC. Let it be supposed that as I is to the circle ABCD, so is the circle EFGH to some magnitude, namely to K. And since I is supposed greater than the circle EFGH, [Margin: f — *Elements* V.14] the circle ABCD will also be greater than the magnitude K. Therefore the square on the diameter EG will be to the square on the diameter AC as the circle EFGH is to the magnitude K, which is less than the circle ABCD. Which is absurd. For it has already been shown generally, in the earlier part, that the square on a diameter cannot be to the square on a diameter as a circle is to a magnitude smaller than that circle — whether the former circle be greater than the latter, or smaller.

And although the circle ABCD is the greater and EFGH the smaller, we shall nevertheless show by the same reasoning that the square on the diameter of the circle ABCD cannot have the ratio that the circle EFGH has to a magnitude greater than the circle ABCD. For in the same way we shall prove (if that be granted) that the square on the diameter AC has to the square on the diameter EG the same ratio that the circle ABCD has to a magnitude smaller than the circle EFGH — which has already been demonstrated to be false, generally, in the earlier part. So that it may likewise be demonstrated generally and universally that the square on the diameter of any circle can never have to the square on the diameter of another circle the same ratio that the former circle has to a magnitude greater than the latter circle — whether the former circle be greater than the latter, or smaller. Therefore the magnitude I is not greater than the circle EFGH; but neither was it shown to be less; therefore it is equal. And so, since it is supposed that the circle ABCD is to I as the square on the diameter AC is to the square on the diameter EG, [Margin: g — *Elements* V.7] and since the circle ABCD is to I as the same circle ABCD is to the circle EFGH, which is equal to the magnitude I, it will also follow that the circle ABCD is to the circle EFGH as the square on the diameter AC is to the square on the diameter EG — whether the circle ABCD be greater than the circle EFGH, or smaller. Therefore circles are to one another as the squares on their diameters. Which was to be shown.

COROLLARIUM.

Hence it follows that circle is to circle as a polygon inscribed in the one is to a similar polygon inscribed in the other. For both circle to circle and polygon to polygon are as the square on the diameter to the square on the diameter, as has been demonstrated.

THEOR. 3. PROPOS. 3.

[Margin: iij.]

Every pyramid having a triangular base is divided into two pyramids, equal and similar to one another, having triangular bases and similar to the whole; and into two equal prisms, and these two prisms are greater than half the whole pyramid.

Let there be a pyramid whose base is the triangle ABC and whose apex is D. Let all its edges be bisected at the points E, F, G, H, I, K, and let the straight lines EF, FG, GE, HI, IK, KH, HE, EI, IF be joined. The pyramid is thereby divided into two pyramids, AEGH and HIKD — whose bases are the triangles AEG and HIK and whose apexes are H and D — and also into two solids EBFHGI and CFGHIK, which we shall presently show to be prisms. The base of the former is the parallelogram EBFH, with the opposite triangles EHG and BIF; the base of the latter is the triangle CFG, to which the triangle FIH is opposite. These prisms have a common boundary, the parallelogram FHGI, and together with the two pyramids they make up the whole pyramid — as is clear if one rightly conceives the apex D of the pyramid on high, together with the triangles that surround it. I say, then, that those two pyramids are equal and similar to one another and similar to the whole; and likewise that these two prisms are equal to one another and greater than half the whole pyramid.

Diagram. Two adjacent copies of the divided triangular pyramid ABCD, drawn in plane projection as a triangle with apex A above the base B–C. The edge-midpoints and internal connecting lines subdivide the figure into the two smaller pyramids and two prisms discussed in the text. Readable labels (left copy):

- A (top): apex of the base triangle
- B (bottom-left), C (bottom-right): base-triangle corners
- E (on left edge AB), G (on right edge AC), F (bottom middle, on BC): edge-midpoints
- H (below A, on edge AD), I (lower left, on edge BD), K (lower right, on edge CD): midpoints of the edges to the solid apex
- D (interior center): the solid apex of the pyramid, drawn projected inside the triangle

The right copy repeats the same construction; its clearly legible labels are A, H, E, D, I, B, F, with the remaining letters faint from foxing.

Since the sides AD and BD of the triangle ADB have been bisected, and therefore [cut] proportionally, [Margin: a — *Elements* VI.2] the lines HI and AB will be parallel. By the same reasoning IK will be parallel to BC; HK to AC; EG to BC; EF to AC; FG to AB; EH to BD; EI to AD; IF to DC; and HG to DC. [Margin: b — *Elements* XI.9] Moreover, since the lines FG and HI are each parallel to AB, they are parallel to one another; and by the same reasoning GH and FI are parallel, since each is parallel to DC. Therefore AEIH, HEBI, IDHE, EBFG, GHKC, CKIF, and FGHI are parallelograms. And since the lines HE and HG are parallel to the lines DB and DC, [Margin: c — *Elements* XI.10] the angles EHG and BDC will be equal; and by the same reasoning the angles HEG and DBC, and HGE and DCB, will be equal. [Margin: d — *Elements* VI.4] The sides of triangle HEG are therefore proportional to the sides of triangle DBC about their equal angles, and hence triangle HEG is similar to triangle DBC. Moreover, the triangles HAE, HAG, AEG are similar to the triangles DAB, DAC, ABC, by the corollary to VI.4. Therefore the pyramid AEGH is similar to the pyramid ABCD, by definition 9 of Book XI [defin. 9. lib. 11].

Again, since the lines HI and HK are parallel to the lines AB and AC, [Margin: e — *Elements* XI.10] the angles IHK and BAC will be equal; and by the same reasoning the angles HIK and ABC, and HKI and ACB, will be equal. [Margin: f — *Elements* VI.4] Therefore the sides of triangle HIK are proportional to the sides of triangle ABC about their equal angles, and so triangle HIK is similar to triangle ABC. Moreover, the triangles DHI, DIK, DKH are similar to the triangles DAB, DBC, DCA, by the same corollary to VI.4. Therefore the pyramid HIKD too is similar to the same pyramid ABCD, by definition 9 of Book XI.

Now since the triangles AHE and HDI are similar to the triangle ADB — as was shown from the corollary to VI.4 — [Margin: g — *Elements* VI.21] they will also be similar to one another. And since they are set up upon the equal lines AH and HD, they will be equal, by the lemma to proposition 22 of Book VI [lemma propos. 22. lib. 6]. By a like argument the triangles AHG and HDK will be equal and similar, since they have been shown similar to triangle ADC and are set up upon the equal lines AH and HD. On the same reasoning the triangles AEG and HIK will be equal and similar, since they have been shown similar to triangle ABC and are placed upon the lines AE and HI, [Margin: h — *Elements* I.34] which are equal because of the parallelogram AEIH. In the same way the triangles EHG and IDK will be equal and similar, since they have been shown similar to triangle BDC and have the lines HE and DI, [Margin: i — *Elements* I.34] which are equal because of the parallelogram HEID. The pyramids AEGH and HIKD are therefore equal and similar, by definition 10 of Book XI, since all the triangles of the one are equal and similar to all the triangles of the other, as has been demonstrated.

Again, [Margin: k — *Elements* I.34] since the lines EH, HG, GE are equal and parallel to the lines BI, IF, FB — because of the parallelograms EHIB, FGHI, BFGI — the triangles EHG and BIF will be mutually equiangular and equal, by the corollary to proposition 8 of Book I [coroll. propos. 8. lib. 1], and therefore also similar. [Margin: l — *Elements* XI.15] They are moreover parallel, since EH and HG, through which the plane EHG is drawn, are parallel to the lines BI and IF, through which the plane BIF is drawn. Therefore the solid BIFGHE, contained by the two triangles EHG and BIF — opposite, equal, similar, and parallel — and by the three parallelograms EGFB, BEHI, IFGH, is a prism, by the definition. In the same way the solid CFGHIK will be shown to be a prism. [Margin: m — *Elements* I.34] For since the lines FC, CG, GF are equal and parallel to the lines IK, KH, HI — because of the parallelograms CFIK, CGHK, FGHI — the triangles CFG and HIK will be equal and mutually equiangular, and therefore similar. [Margin: n — *Elements* XI.15] They are moreover parallel, since the lines CF and CG, through which the plane CFG is drawn, are parallel to the lines KI and KH, through which the plane KIH is drawn. Therefore the solid CFGHIK, contained by the two triangles CFG and KIH — opposite, equal, similar, and parallel — and by the three parallelograms CFIK, KHGC, IFGH, is a prism. And since the prisms EBFghi and CFGHIK are of the same height — namely between the parallel planes BCGE and HIK — and the parallelogram EBFg, the base of the former, is double the triangle CFG, the base of the latter, by the scholium to proposition 41 of Book I [scholium propos. 41. lib. 1], [Margin: o — *Elements* XI.40 (content matches vulgate XI.39)] they will be equal to one another.

Finally, since the prism EBFghi is greater than the pyramid EBFI — a whole greater than its part — and the pyramid EBFI is equal and similar to the pyramid AEGH, and also to the pyramid HIKD (as is plain from the equality and similarity of the triangles), the prisms EBFghi and CFGHIK will be greater than the pyramids AEGH and HIKD. And so the former will exceed half of the pyramid ABCD, while the latter fall short of half of it. For when a whole is cut into two unequal parts, the greater exceeds the half and the lesser falls short of the half. Every pyramid, therefore, having a triangular base, etc. Which was to be shown.

LIBER XII.

THEOR. 4. PROPOS. 4.

[Margin: iv.]

If there be two pyramids of the same height, having triangular bases, and each of them be divided both into two pyramids equal to one another and similar to the whole, and into two equal prisms; and if each of the pyramids arising from the previous division be divided in the same way, and this be done continually — then, as the base of one pyramid is to the base of the other, so also will all the prisms in the one pyramid be to all the prisms in the other pyramid, [these being] equal in number.

Let there be, upon the triangular bases ABC and EFG, two pyramids ABCD and EFGH of the same height, whose edges are bisected at the points I, K, L, M, N, O, P, Q, R, S, T, V, and let the straight lines IL, LK, KN, NO, OM, MN, LM, MI, PR, RQ, QT, TV, VS, ST, RS, SP be joined, so that each pyramid is cut into two pyramids equal to one another and similar to the whole — namely AILM and MNOD; EPRS and STVH — and into two equal prisms, IBKLMN and CKLMNO; PFQRST and GQRSTV, as the preceding proposition requires. And let the pyramids AILM, MNOD; EPRS, STVH be understood to be divided in the same way, and so on.

Diagram. Two triangular pyramids drawn side by side in plane projection, each subdivided as in the previous proposition.

Left figure — pyramid ABCD:

- A (apex, top), B (bottom-left), C (bottom-right): base triangle
- M (below apex), I (left edge), L (right edge): upper midpoints
- N (lower left), O (lower middle-right), K (bottom middle): lower midpoints
- D (interior): the solid apex

Right figure — pyramid EFGH:

- E (apex, top), F (bottom-left), G (bottom-right): base triangle
- S (below apex), P (left edge), R (right edge): upper midpoints
- T (lower left), V (lower right), Q (bottom middle): lower midpoints
- H (interior): the solid apex

I say that all the prisms formed in the pyramid ABCD are to all the prisms produced in the pyramid EFGH — [these being] equal to them in number — as the base ABC is to the base EFG. For since BC is to CK as FG is to GQ (because each line has been bisected), and the triangles ABC and LKC are similar and similarly placed, and likewise the triangles EFG and RQG, by the corollary to VI.4, [Margin: a — *Elements* VI.22] then triangle ABC will be to triangle LKC as triangle EFG is to triangle RQG. And by alternation, as ABC is to EFG, so is LKC to RQG, and so is the prism CKLMNO to the prism GQRSTV, as we shall presently show — and hence

also the prism IBKLMN to the prism PFQRST, since these are equal to those. And as one prism, namely IBKLMN, is to one prism PFQRST, [Margin: b — *Elements* V.12] so are the two prisms IBKLMN and CKLMNO to the two prisms PFQRST and GQRSTV. Therefore, as the base ABC is to the base EFG, so also are the two prisms in the pyramid ABCD to the two prisms in the pyramid EFGH.

By a like argument we shall show that the pair of prisms in the pyramids AILM and MNOD, formed within the pyramid ABCD, are to the pair of prisms in the pyramids EPRS and STVH, formed within the pyramid EFGH, as the bases AIL and MNO of those pyramids are to the bases EPR and STV of these pyramids; and so on, the same division being always made. But as those bases are to these, so is LKC — the base equal and similar to them — to the base RQG, which is equal and similar to these, as was demonstrated in the preceding proposition; that is, as the base ABC is to the base EFG. Therefore, as the base ABC is to the base EFG, so will the prisms of any pyramid formed within ABCD be to the prisms of any pyramid formed within EFGH. And consequently, as the prisms of pyramid ABCD are to the prisms of pyramid EFGH, so are the prisms of pyramid AILM to the prisms of pyramid EPRS, and the prisms of pyramid MNOD to the prisms of pyramid STVH, and so on. Therefore, since the two prisms of pyramid ABCD are to the two prisms of pyramid EFGH [Margin: c — *Elements* V.12] as all the prisms in the pyramids ABCD, AILM, MNOD, etc. together are to all the prisms in the pyramids EFGH, EPRS, STVH, etc. together — provided these are equal in number to those — it will also follow that, as the base ABC is to the base EFG, so are all the prisms in the pyramid ABCD to all the prisms in the pyramid EFGH. And so, if there be two pyramids of the same height having triangular bases, etc. Which was to be demonstrated.

LEMMA.

That LKC is to RQG as the prism CKLMNO is to the prism GQRSTV, we show as follows. Let there be understood, dropped from the apexes D and H to the bases ABC and EFG, perpendiculars, which will be the equal heights of the pyramids ABCD and EFGH. Now since the parallel planes ABC and MNO [Margin: d — *Elements* XI.17] cut two straight lines — namely DC and the perpendicular dropped from D — proportionally, and DC is bisected at O, the perpendicular dropped from D will likewise be bisected at the point where the plane MNO meets it. By the same reasoning the perpendicular dropped from H will be bisected by the plane STV. Therefore, since the whole perpendiculars are supposed equal, their halves — namely the heights of the prisms — will also be equal; and consequently the prisms CKLMNO and GQRSTV, having equal heights, will be to

one another as the bases LKC and RQG, by what we demonstrated in connection with proposition 34 of Book XI [propos. 34. lib. 11].

THEOR. 5. PROPOS. 5.

[Margin: v.]

Pyramids that are of the same height and have triangular bases are to one another as their bases.

Let there be pyramids ABCD and EFGH of the same height, whose bases are the triangles ABC and EFG. I say that pyramid is to pyramid as base is to base. For if it be not so, let it be supposed that, as the base ABC is to the base EFG, so is the pyramid ABCD to a solid X, which will be either less or greater than the pyramid EFGH. Let it first be less, by the magnitude Y.

EVCLID. GEOM.

(*Prop. 5, continued.*)

Let the pyramid EFGH be divided into two equal pyramids and two equal prisms, according to proposition 3 of this book; and again let the pyramids so formed within EFGH be divided in the same way into two equal pyramids and two equal prisms, and so on. Now since, if from the pyramid EFGH there be taken away more than the half — namely the two prisms PFQRST and GQRSTV, [Margin: a — *Elements* XII.3] which are greater than half the pyramid EFGH — and likewise from the remaining pyramids EPRS and STVH more than the half, namely their prisms, and so on, [Margin: b — *Elements* X.1] there will at last be left a magnitude less than Y, the excess of the pyramid EFGH over the solid X. Let the magnitude now left be [that] lesser one. And since the pyramid EFGH is supposed equal to the solids X and Y together, the remaining prisms in the pyramid EFGH will be greater than the solid X. Let the pyramid ABCD be divided into two equal pyramids and two equal prisms, and let the pyramids AILM and MNOD so formed be divided in the same way into two equal pyramids and two equal prisms; and let this be done as many times as it was done in the pyramid EFGH. [Margin: c — *Elements* XII.4] Now since all the prisms in the pyramid ABCD are to all the prisms in the pyramid EFGH — equal in number — as the base ABC is to the base EFG, that is, as the pyramid ABCD is to the solid X; and since all the prisms in the pyramid ABCD are less than the whole pyramid ABCD, [Margin: d — *Elements* V.14] all the prisms in the pyramid EFGH will also be less than the solid X. But

they were shown to be greater as well. Which is absurd. Therefore the solid X is not less than the pyramid EFGH.

Diagram. The two subdivided triangular pyramids ABCD and EFGH again (as on the preceding page), together with two small drawn cubes representing the auxiliary solids of the exhaustion argument.

- Left pyramid ABCD: A (apex), M, I, L (upper), N, O, K (lower/base-middle), B (bottom-left), C (bottom-right), D (interior apex)
- Right pyramid EFGH: E (apex), S, P, R (upper), T, V, Q (lower/base-middle), F (bottom-left), G (bottom-right), H (interior apex)
- Cube labelled X (left, between the two pyramids near the top): the solid X
- Cube labelled Y (right of X): the solid Y

Next, let the solid X be greater than the pyramid EFGH. Since, then, the pyramid ABCD is supposed to be to the solid X as the base ABC is to the base EFG, by inversion the solid X will be to the pyramid ABCD as the base EFG is to the base ABC. Let it be arranged that, as the solid X is to the pyramid ABCD, so is the pyramid EFGH to a solid Y. And since the solid X is supposed greater than the pyramid EFGH, [Margin: e — *Elements* V.14] the pyramid ABCD will also be greater than the solid Y. Therefore, as the base EFG is to the base ABC, so will the pyramid EFGH be to the solid Y, which is less than the pyramid ABCD. Which is absurd; for it has already been shown that base cannot be to base as pyramid is to a solid less than the pyramid. Therefore the solid X is not greater than the pyramid EFGH; and it was shown not to be less either. It is therefore equal. And so, since it is supposed that as the base ABC is to the base EFG [Margin: f — *Elements* V.9] the pyramid ABCD is to the solid X, and the solid X is equal to the pyramid EFGH, it will follow that as the base ABC is to the base EFG [recte: EFG — printed "EFH"], so is the pyramid ABCD to the pyramid EFGH. Pyramids, therefore, existing under the same height, etc. Which was to be shown.

SCHOLIVM.

*Conversely, if triangular pyramids are to one another as their bases, they will be of the same height. For if the height of one be supposed greater, let a part equal to the smaller be cut off from it, and from the point of section let straight lines be drawn to all the angles of the base. Then, as base is to base, so will [that] pyramid be to the pyramid just constructed; but so also was it to the whole pyramid. [Margin: g — *Elements* V.9] Therefore the constructed pyramid will be equal to the whole pyramid — a part to the whole. Which is absurd.*

COROLLARIUM.

Hence it follows that pyramids of the same height, constructed on the same or on equal triangular bases, are equal to one another; because they have the same ratio to their bases — which are supposed equal — or indeed one and the same ratio.

It likewise follows, conversely, that equal triangular pyramids on the same or on equal bases have the same height; and that equal triangular pyramids having the same height have equal bases, if they do not have the same base. These two [claims], from the first part of the corollary, we shall prove by the same argument we used in demonstrating the converse of propositions 36 and 31 of Book XI [propos. 36. & 31. lib. 11]: namely, by setting up another pyramid both upon the [cut-off] height and upon the cut-off base, etc.

THEOR. 6. PROPOS. 6.

[Margin: vj.]

Pyramids that are of the same height and have polygonal bases are to one another as their bases.

Let there be pyramids ABCDEF and GHIKLM, whose bases are the polygons ABCDE and GHIKL, having their sides equal in number. I say that pyramid is to pyramid as base is to base. For, the bases being resolved into an equal number of triangles, each pyramid will be divided into just as many triangular pyramids.

[Margin: a — *Elements* XII.5] Now since, as the base ABC is to the base ACD, so is the pyramid ABCF to the pyramid ACDF, it will follow by composition that, as the base ABCD is to the base ACD, so is the pyramid ABCDF to the pyramid ACDF.

[Margin: b — *Elements* XII.5] But again, as the base ACD is to the base ADE, so is the pyramid ACDF to the pyramid ADEF. Therefore, *ex aequo*, as the base

Diagram. Two pyramids on polygonal (pentagonal) bases, drawn in perspective.

Left figure — pyramid ABCDEF, apex above a pentagonal base:

- F [?] (apex, top; engraved small, resembling a lowercase "r")
- B (upper-left of base), E (upper-right of base), A (front-centre of base)
- C (lower-left of base), D (lower-right of base)

Right figure — pyramid GHIKLM:

- M (apex, top)
- G (centre of base), H (left of base), L (right of base)
- I (lower-left of base), K (lower-right of base)

Book XII (continued)

Proposition 6 — conclusion of the demonstration

as the base ABCD is to the base ADE, so the pyramid ABCDE is to the pyramid ADEF. Therefore, by composition, as the base ABCDE is to the base ADE, so the pyramid ABCDEF is to the pyramid ADEF. By a similar argument, as the base GHIKL is to the base GKL, so the pyramid GHIKLM is to the pyramid GKLM; and by inversion, as the base GKL is to the base GHIKL, so the pyramid GKLM is to the pyramid GHIKLM. [Margin: c — *Elements* XII.5] Again, since as the base ADE is to the base GKL, so the pyramid ADEF is to the pyramid GKLM, the four bases ABCDE, ADE, GKL, GHIKL will stand in the same proportions as the four pyramids ABCDEF, ADEF, GKLM, GHIKLM — as you see in the scheme below, and as is clear from the demonstration. Therefore, *ex aequali*, as the base ABCDE is to the base GHIKL, so the pyramid ABCDEF is to the pyramid GHIKLM. And for this reason pyramids standing under the same height, etc. Which was to be demonstrated.

Diagram. Two pentagonal pyramids drawn side by side in perspective (the figures of Proposition 6).

- Left pyramid — pentagon ABCDE with apex F. Apex F (top). Interior/back base-vertex A (drawn at the centre). Base vertices B (left), E (right), C (lower-left), D (lower-right).
- Right pyramid — pentagon GHIKL with apex M. Apex M (top). Interior/back base-vertex G (drawn at the centre). Base vertices H (left), L (right), I (lower-left), K (lower-right).

The printed proportion-scheme ("formula") set beside the figure lists the four bases and their four pyramids:

Bases	Pyramids
ABCDE	ABCDEF
ADE	ADEF
GKL	GKLM
GHIKL	GHIKLM

SCHOLIUM

Although the demonstration of this proposition, according to the commentators, speaks only of pyramids of the same height whose polygonal bases have an equal number of sides, we shall nevertheless easily demonstrate the same thing also for pyramids of the same height, one of whose bases contains more sides than the base of the other.

Let there first be two pyramids of the same height, ABCDEF and GHIK, of which the base of the former is a polygon — namely a pentagon — while that of the latter is triangular. I say that pyramid is to pyramid as base is to base. For when the pentagon is resolved into triangles, the pyramid too will be divided into an equal number of pyramids. [Margin: d — *Elements* XII.5] Now since, as the base ABC (a first quantity) is to the base GHI (a second quantity), so the pyramid ABCF (a third quantity) is to the pyramid GHIK (a fourth quantity); and in the same way, as the base ACD (a fifth quantity) is to the base GHI (the second quantity), so the pyramid ACDF (a sixth quantity) is to the pyramid GHIK (the fourth quantity) — [Margin: e — *Elements* V.24] it will follow that as the base ABCD (the first quantity together with the fifth) is to the base GHI (the second quantity), so the pyramid ABCDF (the third quantity together with the sixth) is to the pyramid GHIK (the fourth quantity). Again, since, as the base ABCD (a first quantity) is to the base GHI (a second quantity), so the pyramid ABCDF (a third quantity) is to the pyramid GHIK (a fourth quantity), as has just been shown; [Margin: f — *Elements* XII.5] and since, as the base ADE (a fifth quantity) is to the base GHI (the second quantity), so the pyramid ADEF (a sixth quantity) is to the pyramid GHIK (the fourth quantity) — [Margin: g — *Elements* V.24] it will also follow that as the base ABCDE (the first quantity together with the fifth) is to the base GHI (the second quantity), so the pyramid ABCDEF (the third quantity together with the sixth) is to the pyramid GHIK (the fourth quantity). Which was the thing proposed. One must always proceed in the same way, if there are more triangles in the polygonal base.

Diagram. A pentagonal pyramid and a triangular pyramid, drawn side by side (the figures of the first case of the Scholium).

- Left pyramid — pentagon ABCDE with apex F. Apex F (top). Interior/back base-vertex A (centre). Base vertices B (left), E (right), C (lower-left), D (lower-right).
- Right pyramid — triangle GHI with apex K. Apex K (top). Base vertices H (left), I (right), G (drawn at the centre/back).

Now since, as has been demonstrated, the polygonal base ABCDE is to the triangular base GHI as the pyramid ABCDEF is to the pyramid GHIK, it will also follow, by inversion, that as the base GHI is to the base ABCDE, so the pyramid GHIK is to the pyramid ABCDEF. For this reason, any two pyramids, one of which has a polygonal base and the other a triangular base, are proportional to their bases, from whichever you begin. For although the demonstration begins from the polygon and its pyramid, as is clear from the proof, nevertheless by inversion one may also take the beginning from the triangle and its pyramid, as has been said.

But now let there be two pyramids of the same height, ABCDEF and GHIKL, with more sides in one base than in the other. I say once more that pyramid is to pyramid as base is to base. For when the polygon ABCDE is resolved into the triangles ABC, ACD, ADE, its pyramid will be divided into just as many pyramids. Now since, as has already been demonstrated, the triangular base ABC (a first quantity) is to the polygonal base GHIK (a second quantity) as the pyramid ABCF (a third quantity) is to the pyramid GHIKL (a fourth quantity); and as the base ACD (a fifth quantity) is to the base GHIK (the second quantity), so the pyramid ACDF (a sixth quantity) is to the pyramid GHIKL (the fourth quantity) — [Margin: h — *Elements* V.24] it will also follow that as the base ABCD (the first quantity together with the fifth) is to the base GHIK (the second quantity), so the pyramid ABCDF (the third quantity together with the sixth) is to the pyramid GHIKL (the fourth quantity). Again, since, as the base ABCD (a first quantity) is to the base GHIK (a second quantity), so the pyramid ABCDF (a third quantity) is to the pyramid GHIKL (a fourth quantity), as has just been demonstrated; and since also, as the base ADE (a fifth quantity) is to the base GHIK (the second quantity), so the pyramid ADEF (a sixth quantity) is to the pyramid GHIKL (the fourth quantity), as was shown before — [Margin: i — *Elements* V.24] it will also follow that as the base ABCDE (the first quantity together with the fifth) is to the base GHIK (the second quantity), so the pyramid ABCDEF (the third quantity together with the sixth) is to the pyramid GHIKL (the fourth quantity). Which was the thing proposed. One must proceed no otherwise if there are more triangles in the base ABCDE.

Diagram. A pentagonal pyramid and a quadrilateral-based pyramid, drawn side by side (the figures of the third case of the Scholium).

- Left pyramid — pentagon ABCDE with apex F [?] (the engraved apex-letter reads uncertainly). Interior/back base-vertex A (centre). Base vertices B (left), E (right), C (lower-left), D (lower-right).

- Right pyramid — quadrilateral GHIK with apex L. Apex L (top). Base vertices G (upper-left), K (upper-right), H (lower-left), I (lower-right).

Now we shall convert this Proposition 6, together with what has been demonstrated in this Scholium, in the following way:

Pyramids of any bases whatsoever, which are to one another as their bases, have the same height.

This we shall demonstrate no otherwise than the things we stated in the Scholium of Proposition 5 of this book were demonstrated.

COROLLARIVM

It is also made clear from this that pyramids of the same height upon equal polygonal bases, or upon one and the same base, are equal to one another; since they have the same proportion as the bases, which are supposed equal, or one and the same.

Again, conversely: pyramids with polygonal bases that are equal, and set upon equal bases — as though built upon the same base — have the same height. And pyramids with polygonal bases that are equal and have the same height have equal bases, if they do not have the same base. These two things are demonstrated as we stated in the Corollary of Proposition 5 of this book.

THEOR. 7. PROPOS. 7.

[Margin: vij.]

Every prism having a triangular base is divided into three pyramids equal to one another, having triangular bases.

Let ABCDEF be a prism whose two opposite triangles ABF, DCE are equal and similar. I say that this prism is cut into three triangular pyramids equal to one another. For let three diagonals be drawn in the three parallelograms: namely AC in ABCD, CF in BCEF, and FD in ADEF. [Margin: a — *Elements* I.34] Since, then, the triangles ABC, ADC are equal, [Margin: b — *Elements* XII.5] and since, as the base ABC is to the base ADC, so the pyramid ABCF is to the pyramid ADCF — because these pyramids have the same height, namely the perpendicular dropped from the vertex F to the plane ABCD — the pyramids ABCF, ADCF will be equal to one another. By the same reasoning, the pyramids ADFC, EFDC, set upon the equal bases ADF, EFD and under the same height (namely the perpendicular dropped from the vertex C to the plane ADEF), will be equal. But the pyramid ADCF is the

same as the pyramid ADFC, since the former is contained by four planes — namely the base ADC and the triangles ADF, ACF, DCF — and the latter by the same four planes, namely the base ADF and the triangles ADC, ACF, DCF. Therefore the three pyramids ABCF, ADCF, and EFDC — or CDEF, which is the same as the pyramid EFDC, since both EFDC and CDEF are contained by the planes CDE, EFD, DCF, FCE — composing the whole prism, as is evident, are equal to one another; and therefore the prism ABCDEF is divided into three equal pyramids. Wherefore every prism having a triangular base, etc. Which was to be demonstrated.

Diagram. A triangular prism ABCDEF shown in perspective, with all its face-diagonals drawn (the figure of Proposition 7).

- A (top-left) and D (top-right): two vertices of the upper edge.
- B (bottom-left) and C (bottom-right): two vertices of the lower edge.
- E (right): a further vertex.
- F (centre, front): the remaining vertex (through which the dividing lines pass).

The two opposite triangular faces are ABF and DCE.

COROLLARIUM

From this it is gathered that any pyramid is a third part of the prism which has the same base and the same height as it; or that any prism is triple the pyramid which has the same base and height as it.

For let there first be a pyramid ABFC having the triangular base ABF, and a prism ABCDEF under the same height having the same triangular base ABF. I say that the pyramid is a third part of the prism. For if the straight line DF is drawn, the prism will be divided into three equal pyramids ABCF, ADCF, CDEF, [Margin: c — *Elements* XII.7] as has been demonstrated. And therefore the pyramid ABCF — that is, the pyramid ABFC (since this is equal to it, indeed the same, being comprehended by the same planes ABF, FCA, ABC, CBF) — will be a third part of the prism ABCDEF. Since, then, the pyramid ABFC is equal to any other pyramid set under the same height and upon the same base ABF, it is manifest, from the Corollary of Proposition 5 of this book, that any pyramid is a third part of the prism which has the same triangular base and height as it; and therefore, conversely, that the prism is triple the pyramid.

Diagram. A triangular prism ABCDEF shown in perspective with its diagonals (the figure of the first case of the Corollary).

- E (top): apex-edge vertex.
- D (mid-left) and C (mid-right): two vertices.
- F (centre): the vertex through which the diagonals pass.
- A (bottom-left) and B (bottom-right): the lower vertices.

Next, let there be a pyramid $ABCDE$ whose base is any rectilinear figure $ABCD$ of any number of sides, and a prism $ABCDEFGH$ under the same height having the same base. I say again that the pyramid is a third part of the prism. For when the base $ABCD$ and the opposite plane $EFGH$ are resolved into an equal number of triangles ADB , BCD , EHF , FGH , the prism will be divided into just as many prisms having triangular bases. Therefore, when the straight lines AH , BH , DF , CF are drawn, the pyramid $ADBH$ will be, as has been demonstrated, a third part of the prism $ABFEHD$; likewise the pyramid $BCDF$ will be a third part of the prism $CDHGFB$. Hence, as the pyramid $ADBH$ is to the prism $ABFEHD$, so the pyramid $BCDF$ is to the prism $CDHGFB$; [Margin: d — *Elements* V.12] and therefore, as one pyramid is to its own prism, so are all the pyramids together to all the prisms together — that is, to the prism $ABCDEFGH$. Therefore the pyramids $ADBH$, $BCDF$ together constitute a third part of the prism $ABCDEFGH$. But the pyramids $ADBH$, $BCDF$ are equal to the pyramid $ABCDE$; for the pyramids $ADBH$, $ADBE$, upon the same base and under the same height — namely between parallel planes — are equal, by the Corollary of Proposition 5 of this book. And by the same reasoning the pyramids $BCDF$, $BCDE$, upon the same base and under the same height, are equal. Wherefore, since the pyramids $ADBE$, $BCDE$ compose the whole pyramid $ABCDE$, the pyramid $ABCDE$ will also be a third part of the prism $ABCDEFGH$. Since, then, the pyramid $ABCDE$ is equal to any other pyramid set under the same height and upon the same base $ABCD$, it is clear, by the Corollary of Proposition 5 of this book, that any pyramid is a third part of the prism which has the same multilateral base and the same height as it.

Diagram. A prism $ABCDEFGH$ on a quadrilateral base, shown in perspective and criss-crossed with the diagonals used in the proof (the figure of the multilateral case of the Corollary).

- G (top-left) and H (top-right): two vertices of the upper face.
- E (upper-left) and F (upper-right): two further vertices.
- D (mid-left) and C (mid-right): two vertices.
- A (bottom-left) and B (bottom-right): the lower vertices.

The lower base is $ABCD$, the opposite upper plane $EFGH$.

And if the base of the pyramid and of the prism should have more sides, it will be shown in the same way that the pyramid is a third part of the prism. For when the polygons are divided into triangles, the prism will be cut into just as many prisms having triangular bases. Whence the individual triangular pyramids of these prisms will be the third parts of the individual prisms. Since, therefore, all these pyramids are equal to the pyramid whose base is the polygon of the proposed prism, the proposition is established.

In the same way, a pyramid is a third part of a prism having a base equal to the base, and a height equal to the height, of the pyramid. For such a pyramid is equal to that pyramid which has the same base and height as the prism, by the Corollary of Proposition 6 of this book — which we have already shown to be a third part of the prism.

SCHOLIUM I

From what has been said we shall easily demonstrate this proposition, namely:

Prisms existing under the same height, whatever bases they have, are to one another as their bases.

Although this has been demonstrated in Book XI for prisms whose two opposite planes are parallel, equal triangles — even if their bases are parallelograms and their vertices a straight line — and also for parallelepipeds, which we said are contained under the name of prisms: we shall nevertheless now demonstrate the same thing universally for all prisms whose two opposite planes, or bases, are polygons, even though more sides or angles are found in the base of the one than in the base of the other. Let there then be two prisms of the same height, ABCDEFGHIK and LMNOPQRS, whose bases are multilateral figures. I say that as the base ABCDE is to the base LMNO, so is prism to prism. For if, from all the angles of each base, straight lines are drawn to one point of the upper plane which is opposite the base, two pyramids will rise up under the same height as the prisms and having the same bases; and accordingly, by the aforesaid Corollary of this proposition, each pyramid will be a third part of its own prism. [Margin: a — *Elements* V.15] Wherefore, as pyramid is to pyramid, so will prism be to prism. But pyramid is to pyramid as base is to base, as was shown [in Proposition 6 [?]] and its Scholium. Therefore, as base is to base, so also will prism be to prism. Which was the thing proposed.

By conversion: if prisms of any bases whatever are to one another as their bases, they will be under the same height. This we shall show in the same way that the Scholium of Proposition 5 was demonstrated.

Diagram. Two prisms shown in perspective, standing side by side (the figures of Scholium I): on the left a pentagonal prism ABCDEFGHIK, on the right a quadrilateral (rectangular) prism LMNOPQRS.

- Left prism — upper face labelled F, K (at the top), G (upper-left), I (upper-right), H (centre); lower face labelled A (left), B (bottom), C (lower-centre), D and E (centre). Base pentagon ABCDE, upper pentagon FGHIK.
- Right prism — upper face labelled P (left), S (right), Q (upper-left), R (centre); lower face labelled L, M (bottom), N (right), O (left). Base quadrilateral LMNO, upper quadrilateral PQRS.

COROLLARIUM II

Whence prisms of the same height, upon the same base or upon any equal bases whatever, are equal to one another; because, of course, they have the same proportion as the bases, which are supposed equal, or one and the same.

On the contrary: prisms equal to one another, upon equal bases or upon the same base, are of the same height. And prisms equal to one another and of the same height have equal bases, if they do not have the same base. This you will demonstrate no otherwise than the converse of Proposition 31 of Book XI was demonstrated.

SCHOLIUM II

But both the things demonstrated in the preceding Corollary and those demonstrated in the immediately preceding Scholium are to be understood only of prisms which have at the top a plane parallel, equal, and similar to the base. I say this lest you be deceived in the case of a prism consisting of two parallel, equal, and similar triangles together with three parallelograms — which Campanus, with others, holds to be the only thing Euclid calls a prism, as we said in the definition of a prism. For if in such a prism one of those triangles be taken as the base, a pyramid of the same height and having the same base will necessarily be a third part of the prism itself, as was demonstrated in Corollary 1. Likewise the prism itself will have to any other prism the same proportion that base has to base, as we showed in the Scholium. But if in such a prism one of the parallelograms be conceived as the base, so that at the top there is a straight line, the pyramid will not have the same base and the same height, and then [?] the prism will have to the pyramid a sesquialterate proportion — namely that which 3 has to 2. For if to this prism another equal and similar prism be added, so that a parallelepiped is made, the pyramid will be a third part of the constituted

parallelepiped, by the aforesaid Corollary — since the parallelepiped is a prism having the same height and the same base as the pyramid. Wherefore, if the pyramid be put as 2, the parallelepiped will be 6. Half being therefore taken away, the remaining proposed prism will be 3; and therefore it will have to the pyramid the proportion which 3 has to 2, namely sesquialterate. From which it follows that a pyramid set upon half the parallelogram and having the same height as such a prism, being half of the former pyramid, is a third part of the prism. Since this is so, such a prism, so constituted, will not have to another prism of the same height the same proportion that base has to base, unless this other prism too has a straight line at the top and a parallelogram base. And so the things we showed in the Scholium are to be understood of prisms of the same height whose vertices are either straight lines and whose bases are parallelograms, or which have at their tops planes parallel, equal, and similar to their bases. For by this reasoning, if the vertices of the prisms are straight lines, the pyramids upon the same bases and of the same height will be two-thirds of the prisms, as we have just demonstrated. Wherefore they will have the same ratio as the prisms, etc.

THEOR. 8. PROPOS. 8.

[Margin: viij.]

Similar pyramids which have triangular bases are in the triplicate ratio of their corresponding sides.

Let ABCD, EFGH be similar triangular pyramids, such that the bases ABC, EFG are similar and the remaining triangles of the one are similar to the remaining triangles of the other. I say that the ratio of the pyramids is triplicate of the ratio which.

(Continuation of the demonstration of Proposition 8 — that similar pyramids with triangular bases are in the triplicate ratio of their corresponding sides — begun in the preceding pages.)

than that which their corresponding sides BC and FG have. For let the planes of the triangles ABC, CBD, DAB be extended, and let the parallelograms BI, BK, BL be completed. Then draw LM and IM, meeting the lines AI and AL in parallels at M, and join the line KM. The parallelepiped BM will thus be completed, having the same height as the pyramid — for the planes of the solid BM are parallel, as is easily gathered from Proposition 15 of Book XI. In the same way complete the parallelepiped FQ.

Now, because of the similarity of the pyramids, the plane angles ABC and EFG are equal, and AB is to BC as EF is to FG; therefore the parallelograms BI and FN are similar. In the same way, since the angles ABD and EFH are equal, and AB is to BD as EF is to FH, and likewise the angles DBC and HFG are equal, and DB is to BC as HF is to FG, the parallelograms AL and BK will also be similar to the parallelograms FP and FO.

[Margin: a — 24. vnd. (*Elements* XI.24)] Now the three faces BI, BK, BL of the parallelepiped BM, together with the three opposite ones DM, AM, CM, and the three faces FN, FO, FP of the parallelepiped FQ, together with its three opposite ones HQ, EQ, GQ, [Margin: b — 24. vnd. (*Elements* XI.24)] are equal and similar. Therefore the six planes bounding the solid BM are similar to the six planes enclosing the solid FQ; and hence, by Definition 9 of Book XI, the parallelepipeds BM and FQ are similar.

And since, when the lines LI and PN are drawn, [Margin: c — 15. quint. (*Elements* V.15)] the prisms DBCILA and HFGNPE have the same ratio as the parallelepipeds BM and FQ, of which they are the doubles, while the pyramids ABCD and EFGH have the same ratio as those prisms, of which they are the triples, [Margin: d — 11. quin. (*Elements* V.11)] the pyramids too will have the same ratio as the parallelepipeds. [Margin: e — 33. vnde. (*Elements* XI.33)] Therefore, since the ratio of the parallelepiped BM to the parallelepiped FQ is the triplicate of the ratio of the corresponding sides BC and FG, the ratio of the pyramid ABCD to the pyramid EFGH will likewise be the triplicate of the ratio of BC to FG. Similar pyramids, then, which have triangular bases, and so on. Which was to be demonstrated.

Diagram. Two oblique parallelepipeds drawn in perspective, the larger at the left and the smaller at the right, each completing a triangular pyramid (ABCD and EFGH) into a full parallelepiped (BM and FQ) of the same height. Small engraved apex/vertex labels, foxed. (dense vertex labelling).

- Larger solid (left), readable vertex labels: L (upper-left), M (upper-right), A (upper front-left), I (upper front-right), B (lower-left), D (lower-center), C (lower-right). (The vertex K, named in the text, is not separately legible.)
- Smaller solid (right), readable vertex labels: P (upper-left), Q (upper-right), E (mid-left), N (mid-right), F (lower-left), G (lower-center), O (lower-right). (Vertex H not clearly legible.)

COROLLARIUM.

From this too it is evident that similar pyramids whose bases contain more than three sides have the triplicate ratio of their corresponding sides.

Let there be similar pyramids whose rectilinear bases ABCDE and GHIKL, of several sides, are similar. I say that the ratio of the pyramids is the triplicate of the ratio which their corresponding sides AB and GH have. For if from the angles E and L lines EB, EC, LH, LI are drawn to the opposite angles, [Margin: f — 20. sexti. (*Elements* VI.20)] the similar bases will be divided into triangles equal in number and similar — namely, the triangles ABE, EBC, CDE will be similar to the triangles GHL, LHI, IKL.

Since, then, on account of the similarity of the pyramids, the triangles AEF and GLM are similar, and the angle FEA is equal to the angle MLG, FE will be to EA as ML is to LG. And since EA is to EB as LG is to LH, on account of the similarity of the triangles AEB and GLH, ex aequali FE will be to EB as ML is to LH. Again, since EB is to BA as LH is to HG, because of the similar triangles ABE and GHL, and BA is to BF as HG is to HM (since, by the similarity of the pyramids, the triangles ABF and GHM are similar), ex aequali EB will also be to BF as LH is to HM. And therefore, since FE is to EB as ML is to LH, and EB is to BF as LH is to HM, ex aequali FE will be to FB as ML is to MH.

[Margin: g — 5. sexti. (*Elements* VI.5)] Hence the triangles FEB and MLH are equiangular, and so similar. And the triangles FEA, FAB, ABE are similar to the triangles MLG, MGH, GHL. Therefore, by Definition 9 of Book XI, the pyramids ABEF and GHLM are similar. [Margin: h — 8. duode. (*Elements* XII.8)] By the same reasoning the pyramids EBCF and LHIM will be similar, and likewise CDEF and IKLM.

Therefore, as has been demonstrated, the pyramids ABEF, EBCF, CDEF will have to the pyramids GHLM, LHIM, IKLM, each to each, the triplicate ratio of the corresponding sides AB, BC, CD to GH, HI, IK, each to each. And since AB, BC, CD have one and the same ratio to GH, HI, IK, on account of the similarity of the bases ABCDE and GHIKL, the pyramids ABEF, EBCF, CDEF will also have to the pyramids GHLM, LHIM, IKLM one and the same ratio — namely, the triplicate of that ratio. [Margin: i — 12. quint. (*Elements* V.12)] And therefore, as one pyramid ABEF is to one pyramid GHLM, so all the pyramids together, namely the pyramid ABCDEF, will be to all the pyramids together, namely to the pyramid GHIKLM. Wherefore, [Margin: k — 8. duod. (*Elements* XII.8)] since the pyramid ABEF has to the pyramid GHLM the triplicate ratio of the corresponding sides AB and GH, the

pyramid ABCDEF will also have to the pyramid GHIKLM the triplicate ratio of the same corresponding sides AB and GH. Which is what was proposed.

Diagram. Two pyramids on many-sided (pentagonal) bases, drawn in perspective: at the left the pyramid ABCDEF with apex F, at the right the pyramid GHIKLM with apex M, each base subdivided into triangles by diagonals.

- Left pyramid, readable labels: F (apex, top), E (a base vertex, drawn as the point from which the diagonals EB, EC issue), A (left), D (right), B (bottom-left), C (bottom-right).
- Right pyramid, readable labels: M (apex, top), G (left), K (interior/mid), I (lower-right), H (bottom). (Vertex L not clearly legible.)

SCHOLIVM.

By the same reasoning, similar prisms will have the triplicate ratio of their corresponding sides.

For let there be two similar prisms ABCDEFGHIK and LMNOPQRSTV. I say that their ratio is the triplicate of the ratio of their corresponding sides. For if from the angles A and L the lines AC, AD and LN, LO are drawn, [Margin: l — 20. sexti. (*Elements* VI.20)] then, as was said of the pyramids, the triangles ABC, CAD, DEA will be similar to the triangles LMN, NLO, OLP. Similarly, if from the angles G and R the lines GI, Gk and RT, RV are drawn, the triangles GHI, IGk, kFG will be similar to the triangles RST, TRV, VQR, and to the triangles previously named — since all the opposite faces of the prisms are similar, by the definition of a prism.

Now, because, on account of the similarity of the prisms, the parallelograms CH and NS are similar, IC will be to CB as TN is to NM; and since CB is to CA, so also is NM to NL, on account of the similarity of the triangles BCA and MNL. Therefore ex aequali IC will be to CA as TN is to NL. Again, since the solid angle N is equal to the solid angle C, on account of the similarity of the prisms, if the one be placed upon the other, all will coincide — namely the angle MNO with the angle BCD, the angle TNM with the angle ICB, and the angle TNO with the angle ICD. The line NL also coincides with the line CA, because the angles MNL and BCA are equal. Therefore the angles ICA and TNL are equal; and hence, since the sides about them have been shown to be proportional, the parallelograms CG and NR will be similar. And the parallelograms CH, HA are similar to the parallelograms NS, SL, and the triangles ABC, GHI to the triangles LMN, RST. Therefore the prisms ABCIGH and LMNTRS are similar, by the definition of similar solids.

In no other way will it be shown that the prisms CDAGIk and NOLRTV are similar, and likewise the prisms AEDkGF and LPOVRQ. Wherefore the prisms ABCIGH,

CDAGIk, AEDkGF have to the prisms LMNTRS, NOLRTV, LPOVRQ, by what we demonstrated at Proposition 34 of Book XI, the triplicate ratio, each to each, of the corresponding sides BC, CD, DE to MN, NO, OP, each to each. And therefore in the same way we shall demonstrate that the prisms ABCDEFGHIk [and] LMNO...

Diagram. Two pentagonal prisms drawn in perspective, the larger at the left, the smaller at the right (the similar prisms ABCDEFGHIk and LMNOPQRSTV), each face subdivided by diagonals. Many small vertex labels, some foxed. (dense vertex labelling; >2 labels uncertain).

- Larger prism (left), readable labels: G (top), H (upper-left), F (upper-right), I (mid-left), K (mid-right), A (interior), B (lower-left), E (lower-right), C (bottom-left), D (bottom-center).
- Smaller prism (right), readable labels: R (top), S (upper-left), Q (upper-right), T (mid-left), V (mid-right), L (interior), M (mid), P (lower-right), N (bottom-left), O (bottom-center).

(Global page 533 — running header "LIBER XII.")

LMNOPQRSTV, have the triplicate ratio of their corresponding sides BC and MN — the very method we used a little before to demonstrate the same thing for many-angled pyramids.

From all this it is gathered that similar many-angled pyramids are divided into similar triangular pyramids, equal in number, and corresponding to the wholes. For this is evident from the demonstration of the preceding corollary.

In the same way it is inferred that similar many-angled prisms are divided into similar prisms having triangular bases, equal in number, and corresponding to the wholes — as appears from the demonstration of this scholium.

THEOR. 9. PROPOS. 9.

[Margin: vij.]

In equal pyramids that have triangular bases, the bases and the heights are reciprocally proportional. And those pyramids having triangular bases whose bases and heights are reciprocally proportional are equal.

Let ABCD and EFGH be equal triangular pyramids. I say that their bases ABC and EFG and their heights are reciprocal — that is, that ABC is to EFG as the height of the pyramid EFGH is to the height of the pyramid ABCD. For if, as was said in the preceding proposition, the parallelepipeds BM and FQ, of the same heights as the

pyramids, are completed, and the lines LI and PN are joined, the prisms DBCILA and HFGNPE, being the triples of the pyramids (which are assumed equal), will be equal to one another; and hence the parallelepipeds BM and FQ, being the doubles of the prisms, will also be equal. [Margin: a — 34. vnd. (*Elements* XI.34)] Therefore their bases and heights will be reciprocal — that is, the base BI will be to the base FN as the height of the solid FQ is to the height of the solid BM. [Margin: b — 15. quint. (*Elements* V.15)] But the base BI is to the base FN as the triangle ABC is to the triangle EFG. Therefore the base ABC will also be to the base EFG as the height of the pyramid EFGH is to the height of the pyramid ABCD, since the heights of the pyramids are the same as those of the parallelepipeds. And therefore the bases and heights of the equal pyramids are reciprocal.

Now let the bases and heights be reciprocal. I say that the pyramids are equal. For, the figure being constructed as before, [Margin: c — 14. quin. (*Elements* V.14)] since ABC is to EFG as the parallelogram BI is to the parallelogram FN, and the heights of the parallelepipeds and of the pyramids are the same, the bases of the parallelepipeds and their heights will also be reciprocal; [Margin: d — 34. vnde. (*Elements* XI.34)] and therefore the parallelepipeds BM and FQ will be equal to one another. Hence the prisms DBCILA and HFGNPE, their halves, will be equal; and therefore the pyramids too, being the third parts of the prisms, will be equal. In equal pyramids, then, having triangular bases, and so on. Which was to be demonstrated.

Diagram. Two oblique parallelepipeds drawn in perspective (the solids BM and FQ of the previous construction), the larger at the left, the taller, narrower one at the right. Small vertex labels, foxed. (dense vertex labelling).

- Larger solid (left), readable labels: M (upper-left), L (upper-center), A (right), I (interior), K (lower-left), C (bottom-left), D (bottom-center), B (bottom-right).
- Right solid, readable labels: Q (top), E (mid-left), N (mid-right), F (lower-left), H (lower-center), G (lower-right).

SCHOLIVM.

By the same reasoning, in equal pyramids whose bases are not triangular the bases and heights are reciprocal; and those pyramids not having triangular bases whose bases and heights are reciprocal are equal.

For let there be, first, two equal pyramids, of which ABCD has a triangular base, but EFGHI a non-triangular one. To the non-triangular base EFGHI let a triangle KLM be made equal. This will be done if the many-sided base is reduced to a

parallelogram, by Proposition 45 of Book I; for this parallelogram is easily reduced to a triangle by what we demonstrated at Proposition 42 of Book I. Then upon KLM let a pyramid KLMN be constructed, of the same height as the pyramid EFGHI. Since, then, the pyramids EFGHI and KLMN have equal bases and the same height, they will be equal, by what we showed in the scholium of Proposition 6 of this book. But the pyramid EFGHI is assumed equal to the pyramid ABCD. Therefore the pyramid KLMN will also be equal to the pyramid ABCD.

Wherefore, since the pyramids ABCD and KLMN have triangular bases, [Margin: e — 9. duode. (*Elements* XII.9)] the base ABC will be to the base KLM — that is, to the base EFGH equal to it — as the height of the pyramid KLMN — that is, the height of the pyramid EFGH (for these heights are assumed equal) — is to the height of the pyramid ABCD. And hence the bases and heights of the equal pyramids ABCD and EFGHI are reciprocal.

But now let the bases and heights be reciprocal. I say that they are equal. For, the figure being constructed in the same way, since the base KLM is equal to the base EFGH, and the height of the pyramid KLMN is the same as that of the pyramid EFGHI, while it is assumed that ABC is to EFGH as the height of the pyramid EFGHI is to the height of the pyramid ABCD, it will also be that the base ABC is to the base KLM as the height of the pyramid KLMN is to the height of the pyramid ABCD. [Margin: f — 9. duode. (*Elements* XII.9)] Wherefore the pyramids ABCD and KLMN are equal. And since the pyramid KLMN is equal to the pyramid EFGHI, by what was shown in the scholium of Proposition 6 of this book, the pyramid ABCD will also be equal to the pyramid EFGHI. Which is what was proposed.

Diagram. Three figures side by side illustrating the first case of the scholium: a triangular-based pyramid, a quadrilateral-based pyramid, and a triangular-based pyramid.

- Left (pyramid ABCD), readable labels: D (apex), A (interior), B (bottom-left), C (bottom-right).
- Center (pyramid EFGHI, non-triangular base), readable labels: I (apex), E (upper-left), H (upper-right), F (bottom-left), G (bottom-right).
- Right (pyramid KLMN), readable labels: N (apex), K (interior), M (bottom-right); the lower-left base vertex is not clearly legible [?].

Diagram. Three pyramids side by side illustrating the second (many-angled) case of the scholium (the same figure is repeated at the top of the following page): a

triangular-based pyramid MNOP, a quadrilateral-based pyramid ABCDE, and a many-sided-based pyramid FGHKL.

- Left (pyramid MNOP), readable labels: P (apex), M (interior), N (bottom-left), O (bottom-right).
- Center (pyramid ABCDE), readable labels: E (apex), A (upper-left), D (upper-right), B (bottom-left), C (bottom-right).
- Right (pyramid FGHKL), readable labels: L (apex), F (interior), G (upper-left), K (interior), H (bottom-left), I (bottom-right).

(Global page 534 — running header "EVCLID. GEOM."; folio "522"; leaf-mark "viiij.")

Diagram. The same three pyramids as the preceding figure, repeated at the head of the page for continuity: the triangular-based pyramid MNOP, the quadrilateral-based pyramid ABCDE, and the many-sided-based pyramid FGHKL.

- Left (pyramid MNOP), readable labels: P (apex), M (interior), N (bottom-left), O (bottom-right).
- Center (pyramid ABCDE), readable labels: E (apex), A (upper-left), D (upper-right), B (bottom-left), C (bottom-right).
- Right (pyramid FGHKL), readable labels: L (apex), F (interior), G (upper-left), H (bottom-left), I (bottom-right), K (interior).

as the height of the pyramid MNOP — that is, to the height of the pyramid ABCDE (for these heights are assumed equal). And therefore the bases and heights of the equal pyramids ABCDE and FGHKL are reciprocal.

But now let the bases and heights of these pyramids be reciprocal. I say that they are equal. For, the figure being set up in the same way, since the base MNO is equal to the base ABCD, and the height of the pyramid MNOP is the same as that of the pyramid ABCDE, and it is assumed that ABCD is to FGHKL as the height of the pyramid FGHKL is to the height of the pyramid ABCDE, it will also be that MNO is to FGHKL as the height of the pyramid FGHKL is to the height of the pyramid MNOP. Wherefore, as we showed before, the pyramids MNOP and FGHKL will be equal. But the pyramid MNOP is equal to the pyramid ABCDE, from the scholium of Proposition 6 of this book. Therefore the pyramid ABCDE will also be equal to the pyramid FGHKL. Which is what was proposed.

All these things too will easily be demonstrated to hold for any prisms whatever. For if the prisms are equal, their pyramids also — of the same heights as the prisms and upon the same bases — will be equal, since they are the third parts of them, by the corollary of Proposition 7 of this book; or indeed two-thirds, if the

bases of the prisms are parallelograms and their vertices straight lines, as was shown in the scholium of the same proposition. Wherefore, as we have just demonstrated, the bases and heights of these pyramids are reciprocal. And since these bases and heights are the same as those of the prisms, the bases and heights of the prisms will also be reciprocal.

Again, if the bases and heights of the prisms are reciprocal, the bases and heights of the pyramids having the same bases and heights as the prisms will also be reciprocal. Wherefore, as was demonstrated, the pyramids are equal; and therefore the prisms — being their triples, or indeed one and a half times as great — are also equal. Which is what was proposed.

THEOR. 10. PROPOS. 10.

[Margin: viij.]

Every cone is the third part of a cylinder having the same base as itself and an equal height.

Let a cone and a cylinder have the same base, the circle ABCD, and the same height. I say that the cone is the third part of the cylinder. For if the cone is not believed to be the third part of the cylinder, the cylinder will not be the triple of the cone, but either greater or less than the triple of the cone.

Let it first be greater than the triple of the cone, by the magnitude E, so that the cylinder is equal to the triple of the cone together with the magnitude E, taken together. Let a square ABCD be inscribed in the circle, and about the same circle let a square FGHI be described; and upon these squares, under the height of the cone and cylinder, let two parallelepipeds be understood to be erected. Since, then, the square ABCD is half the square FGHI, as we showed at Proposition 9 of Book IV, [Margin: a — 32. vnd. (*Elements* XI.32)] and since base is to base as parallelepiped is to parallelepiped of the same height, the parallelepiped on the base ABCD will be half the parallelepiped on the base FGHI. And hence the parallelepiped on the base ABCD is greater than half the cylinder whose base is the circle ABCD.

Let the arcs AB, BC, CD, DA be bisected at the points K, L, M, N, and let the lines KA, KB, LB, LC, MC, MD, ND, NA be joined. Through K let the line OP be drawn tangent to the circle at K, which will be parallel to AB, as we showed at Proposition 27 of Book III, and let it meet the lines DA and CB produced at P and O; and upon AKB and ABOP let prisms be understood, under the height of the cone and cylinder. [Margin: b — 41. prim. (*Elements* I.41)] Since, then, the triangle

AKB is half the parallelogram ABOP, the prism on the base AKB will also be half the prism, or parallelepiped, on the base ABOP — since prism is to prism as base is to base, as we demonstrated at Proposition 7 of this book. And therefore the prism on the base AKB will be greater than half the segment of the cylinder whose base is the figure contained by the straight line AB and the arc AKB.

By the same reasoning there will be prisms whose bases are the remaining triangles BLC, CMD, DNA, and whose height is the same as that of the cone and cylinder, greater than the halves of the segments of the cylinder whose bases are the segments of the circle. Therefore all these prisms together are greater than the halves of all the segments of the cylinder together. And if again the arcs AK, KB, etc. are bisected and straight lines joined, prisms of the same height as the cone and cylinder will be constructed in the same way, which together will be greater than the halves of all the segments of the cylinder together whose bases are the segments of the circle; and so on in succession.

Now since, if from the cylinder whose base is the circle ABCD there be taken away more than the half — namely the parallelepiped on the base ABCD — and from the remaining segments more than the half — namely the prisms on the bases AKB, BLC, etc. — and if in this manner the subtraction be always made, [Margin: 1. dec. (*Elements* X.1) — printed margin letter uncertain [?]] there is at length left a magnitude less than E, the excess of the cylinder over the triple of the cone. Let the segments of the cylinder now left, on the bases AK, KB, BL, etc. (whose bases are indeed segments of the circle), taken together, be less than E.

Since, then, the cylinder is assumed equal to the triple of the cone together with the magnitude E, if from the cylinder the said segments be taken away, and from the triple of the cone together with the magnitude E the magnitude E itself — which is greater than the said segments of the cylinder — the remainder, the prism on the many-angled base AKBLCMDN, having the same height as the cone and cylinder, will be greater than the remaining triple of the cone; and therefore the cone will be less than the third part of the prism. But since the pyramid whose base and height are the same as the prism's is the third part of the said prism, by the corollary of Proposition 7 of this book, the cone will be less than the said pyramid — the whole less than the part. Which is absurd. Therefore the cylinder is not greater than the triple of the cone.

Next let the cylinder be less than the triple of the cone, and accordingly the cone greater than the third part of the cylinder. Let the cone then be greater...

Diagram. The construction for Proposition 10: a circle (ABCD) inscribed within a square (FGHI); the arcs bisected at K, L, M, N to form an inscribed octagon, with chords drawn from those points; a tangent line OP through K meeting the produced sides. Beneath the main figure a small lens/almond shape labelled E represents the auxiliary magnitude E. (several small labels, foxed).

- Circle vertices: A (top), B (left), C (bottom), D (right).
- Circumscribed square corners: F (top-left), G (bottom-left), H (bottom-right), I (top-right) [top-right corner reads I/I — [?]].
- Arc-midpoints (inscribed octagon): K (upper-left), L (lower-left), M (lower-right), N (upper-right).
- Tangent line through K: P (upper) and O (left), where OP meets DA and CB produced.
- E: separate lens-shaped figure below the construction, representing the magnitude E.

[Book XII, Proposition 10 — conclusion of the demonstration]

greater than a third part of the cylinder, by the magnitude E, so that the cone is equal to a third part of the cylinder together with the magnitude E. Once more inscribe in the circle the square ABCD, and about the same circle circumscribe the square FGHI; and upon these squares let there be conceived pyramids having the height of the cone and cylinder. Now the square ABCD is half the square FGHI, as we proved at Book IV, proposition 9, and base is to base as pyramid is to pyramid of the same height [Margin: d. Elements XII.6]. So the pyramid on ABCD will also be half the pyramid on the base FGHI; and therefore the pyramid on the base ABCD is greater than half the cone whose base is the circle ABCD.

Bisect the arcs AB, BC, CD, DA at K, L, M, N, and join the straight lines AK, KB, BL, LC, CM, MD, DN, NA. Also draw through K the straight line OP tangent to the circle at K — which will be parallel to AB, as we proved at Book III, proposition 27 — and let it meet DA and CB, produced, at P and O; and upon AKB and ABOP let pyramids of the height of the cone and cylinder be conceived. [Margin: e. Elements I.41] Now since the triangle AKB is half the parallelogram ABOP, the pyramid on the base AKB will likewise be half the pyramid on the base ABOP [Margin: f. Elements XII.6], since pyramids have the same ratio as their bases. Therefore the pyramid on the base AKB is greater than half the segment of the cone whose base is the figure contained by the straight line AB and the arc AKB. By the same reasoning, the pyramids whose bases are the triangles BLC, CMD, DNA, and whose height is the same as that of the cone and cylinder, will be

greater than half of the segments of the cone whose bases are the circular segments. All these pyramids taken together are therefore greater than half of all the segments of the cone taken together.

And if again the arcs AK, KB, BL, LC, CM, MD, DN, NA are bisected and straight lines are joined in the same circle, pyramids of the same height as the cone and cylinder will be constructed in the same way, and these together will be greater than half of all the segments of the cone together whose bases are the circular segments; and so on continually. Now since, if from the cone whose base is the circle ABCD more than half is removed — namely the pyramid on the base ABCD, which we showed to be greater than half the cone whose base is the circle ABCD — and from the remaining segments more than half — namely the pyramids on the bases AKB, BLC, CMD, DNA — and the subtraction is carried on in this manner without end, there is at last left [Margin: g. Elements X.1] a magnitude less than E, the excess of the cone above the third part of the cylinder. So let the segments of the cone now left, on the bases AK, KB, BL, LC, CM, MD, DN, NA (whose bases are indeed circular segments), taken together, be less than E.

Since, then, the cone is assumed equal to the third part of the cylinder together with the magnitude E: if from the cone the aforesaid segments are taken away, and from the third part of the cylinder together with the magnitude E the magnitude E itself is taken away — which E is greater than the aforesaid segments of the cone — the remaining pyramid, whose base is the polygon AKBLCMDN and which has the same height as the cone and cylinder, will be greater than the remaining third part of the cylinder; and therefore triple the said pyramid will be greater than the cylinder. Consequently, since the prism having the same base as the said pyramid and the same height as the cone and cylinder is triple that pyramid — as was demonstrated above by us in the corollary to proposition 7 of this book — this prism will be greater than the cylinder, the part greater than the whole. Which is absurd. Therefore the cylinder is not less than triple the cone. But neither was it shown to be greater than triple. Therefore it is equal to triple the cone, and for that reason the cone is a third part of the cylinder. Every cone, then, is a third part of the cylinder that has the same base as it and an equal height. Which was to be demonstrated.

SCHOLIUM

Although this proposition is understood only of right cones and cylinders — since Euclid defined only these in Book XI — it nevertheless holds for all cones and cylinders alike, right and oblique [*scaleni*], as is plain to anyone who examines its

demonstration attentively. And so the proposition may be stated in fully general form thus:

Every cone, whether right or oblique, is a third part of any cylinder whatever, whether right or oblique, that has the same base and the same height as it — even though the axis of the cone and of the cylinder is not one and the same.

THEOR. 11. PROPOS. 11.

[Margin: ix. (vulgate proposition number)]

Cones and cylinders that stand under the same height are to one another as their bases.

Let there be cones and cylinders under the same height, whose bases are the circles ABCD and EFGH, and whose heights, IK and LM, are equal. I say that as base is to base, so is cone to cone and cylinder to cylinder. For if this be not granted, let it be that as the base ABCD is to the base EFGH, so is the cone ABCDK to some magnitude, namely N, which will be either greater or less than the cone EFGHM. For if it were equal, the cone ABCDK would have to the cone EFGHM and to N the same ratio [Margin: a. Elements V.7]; and for that reason cone would be to cone as base to base — which is not conceded.

Diagram. Two circles side by side, each with an inscribed octagon and a cone-apex letter, and beneath them two small figures representing the auxiliary magnitudes O and N.

- Left circle — base **ABCD**, center **I**; inscribed octagon with vertices, in order around the circle: **A** (top), **T** (upper left), **B** (left), **V** (lower left), **C** (bottom), **X** (lower right), **D** (right), **Y** (upper right). **K** — cone apex, marked at the end of the axis line rising to the upper right (cone ABCDK).
- Right circle — base **EFGH**, center **L**; inscribed octagon with vertices, in order: **E** (top), **P** (upper left), **F** (left), **Q** (lower left), **G** (bottom), **R** (lower right), **H** (right), **S** (upper right). **M** — cone apex, at the end of the axis line rising to the upper right (cone EFGHM).
- **O** — pointed-oval (lens-shaped) figure below the left circle (the auxiliary magnitude O).
- **N** — shaded circular figure below the right circle (the auxiliary magnitude N).

Let N , then, be first less than the cone $EFGHM$ by the magnitude O , so that the cone $EFGHM$ is equal to the magnitudes N and O together. Inscribe in the circle $EFGH$ the square $EFGH$, bisect the arcs EF , FG , GH , HE at P , Q , R , S , and join the straight lines EP , PF , FQ , and so on. Now if from the cone $EFGHM$ there be taken away the pyramid on the base $EFGH$, of the same

height, and from the remaining segments there be taken away pyramids of the same height on the bases EPF , FQG , and so on, and the subtraction be carried on in this manner without end, more than half is always subtracted, as was shown in the latter part of the preceding proposition [Margin: b. Elements X.1]; there will at last be left a magnitude less than O , the excess of the cone $EFGHM$ above N . So let the segments of the cone now left, on the bases EP , PF , FQ , and so on (whose bases are indeed circular segments), taken together, be less than O . Since, then, the cone $EFGHM$ is assumed equal to the magnitudes N and O together: if from the cone the said segments of the cone are taken away, and from N and O the magnitude O itself is taken away — which O is greater than the aforesaid segments of the cone — the remaining pyramid, whose base is the polygon $EPFQGRHS$ and which is of the same height as the cone, will be greater than N , the remaining magnitude.

Now inscribe in the circle $ABCD$ a polygon $ATBVCXDY$ similar to the polygon $EPFQGRHS$, as we taught at proposition 2 of this book, and draw the diameters BD , FH of the circles. Then since, by the corollary to proposition 2 of this book, as the circle $ABCD$ is to the circle $EFGH$, so is the polygon $ATBVCXDY$ to the polygon $EPFQGRHS$; and since, as the circle $ABCD$ is to the circle $EFGH$, so is the cone $ABCDK$ assumed to be to the magnitude N [Margin: c. corollary, Elements XII]; and since, as polygon is to polygon, so is pyramid to pyramid of the same height as the cones: it will also be that as the pyramid $ATBVCXDYK$ is to the pyramid $EPFQGRHSM$, so is the cone $ABCDK$ to N . Since, then, the pyramid $ATBVCXDYK$ is less than the cone $ABCDK$, the part than the whole, the pyramid $EPFQGRHSM$ will also be less than N [Margin: d. Elements V.14] — but it was shown to be greater. Which is absurd. Therefore the magnitude N is not less than the cone $EFGHM$.

Let N , secondly, be greater than the cone $EFGHM$. Since, then, it is assumed that as the circle $ABCD$ is to the circle $EFGH$, so is the cone $ABCDK$ to N , it will also be, by conversion, that as the circle $EFGH$ is to the circle $ABCD$, so is N to the cone $ABCDK$. Let it be that as N is to the cone $ABCDK$, so is the cone $EFGHM$ to the magnitude O . And since N is assumed greater than the cone $EFGHM$, the cone $ABCDK$ will also be greater than O . Therefore it will be that as the circle $EFGH$ is to the circle $ABCD$, so is the cone $EFGHM$ to the magnitude O , which is less than the cone $ABCDK$. Which is absurd; for it has already been shown that a cone

cannot be to a magnitude less than another cone as the base of that cone is to the base of this cone. Therefore the magnitude N is not greater than the cone EFGHM. But neither was it shown to be less; it is therefore equal. And so, since it is assumed that as the base ABCD is to the base EFGH, so is the cone ABCDK to N [Margin: e. Elements V.7], while it holds that as the cone ABCDK is to N, so is that same cone ABCDK to the cone EFGHM, it will also be that as the base ABCD is to the base EFGH, so is the cone ABCDK to the cone EFGHM.

Now since, as the cone ABCDK is to the cone EFGHM, so is the cylinder ABCDK (which is triple the cone ABCDK) to the cylinder EFGHM (which is triple the cone EFGHM) [Margin: f. Elements V.15], it will also be that as the base ABCD is to the base EFGH, so is the cylinder ABCDK to the cylinder EFGHM. This too can be confirmed in the same way as we used for the cones, if in place of the cones and pyramids one conceives cylinders and prisms. Cones and cylinders, therefore, that stand under the same height are to one another as their bases. Which was to be demonstrated.

SCHOLIUM

It is also plain that this proposition, which Euclid stated only of right cones and cylinders, can — for the reason given above — be extended to oblique cones and cylinders as well, as its demonstration manifestly indicates, so that the proposition may be stated in fully general form in this manner:

Cones and cylinders that stand under the same height — whether both are right, or both oblique, or the one right and the other oblique — have to one another the proportion of their bases.

The converse of this proposition will likewise be stated in this way:

If cones and cylinders are to one another as their bases, they will be under the same height.

This indeed you will demonstrate in the same way in which we proved the converse of proposition 32 of Book XI.

COROLLARIUM

Hence it follows that cones and cylinders of the same height set upon the same base, or upon equal bases — whether both are right, or oblique, or the one right and the other oblique — are equal to one another: because they have the same proportion as their bases, which are assumed equal, or are indeed one and the same.

It likewise follows that cones and cylinders that are equal upon the same base, or upon equal bases, are of the same height; and that equal ones of the same height are upon equal bases, if they do not have the same base. This we shall show in no other way than that in which the converse of proposition 31 of Book XI was demonstrated.

THEOR. 12. PROPOS. 12.

[Margin: x. (vulgate proposition number)]

Similar cones and cylinders are in the triplicate ratio of the diameters that are in their bases.

Let there be similar cones and cylinders whose bases are the circles ABCD, EFGH, whose axes are LK, LM, and whose base-diameters are BD, FH. I say that cone is to cone, and cylinder to cylinder, in the triplicate ratio of diameter to diameter. For if this be not granted, let the cone ABCDK have to some magnitude N the triplicate ratio of the diameter BD to the diameter FH. And N will be either less or greater than the cone EFGHM. For if it were equal, the cone ABCDK would have to the cone EFGHM and to N the same ratio [Margin: a. Elements V.7]; and consequently the ratio of the cone ABCDK to the cone EFGHM would also be the triplicate of the ratio of the diameter BD to the diameter FH — which is not conceded.

Let N, then, be first less than the cone EFGHM by the magnitude O; and let exactly the same construction of the figure be made as in the preceding proposition, so that again the pyramid EPFQGRHSM is shown greater than N. Then draw the straight lines KB, KT, MF, MP, so that there are obtained two triangles BKT, EMP belonging to the pyramids ATBVCXDY, EPFQGRHSM; and join the straight lines TI, PL.

Diagram. The same twin-circle construction as on the two preceding pages (bases ABCD with center I and apex K; EFGH with center L and apex M; auxiliary magnitudes O and N drawn beneath as plain circles), but here with additional chords drawn to form the corresponding triangles BKT and EMP used in the similarity argument (the connecting lines KB, KT, MF, MP and TI, PL).

- Left circle — base **ABCD**, center **I**; octagon vertices **A** (top), **T** (upper left), **B** (left), **V** (lower left), **C** (bottom), **X** (lower right), **D** (right), **Y** (upper right); **K** cone apex (upper right).

- Right circle — base **EFGH**, center **L**; octagon vertices **E** (top), **P** (upper left), **F** (left), **Q** (lower left), **G** (bottom), **R** (lower right), **H** (right), **S** (upper right); **M** cone apex (upper right).
- **O, N** — plain circles beneath the left and right circles respectively (auxiliary magnitudes).

Since, then, the cones ABCDK, EFGHM are assumed similar, it will be, by definition 24 of Book XI, that as diameter BD is to diameter FH [Margin: b. Elements V.15], so is the semidiameter BI to the semidiameter FL, and so the axis IK to the axis LM; and, by alternation, as BI is to IK, so is FL to LM. Then, since the angles BIK, FLM are right (by definition 3 of Book XI, because the cones are assumed right, and therefore their axes are at right angles to their bases), the triangles BIK, FLM will be equiangular [Margin: c. Elements VI.6]; and therefore as KB is to BI, so is MF to FL [Margin: d. Elements VI.4]. And as BI is to BT, so is FL to FP, on account of the similarity of the triangles BIT, FLP. (For since the angles BIT, FLP, standing on the similar arcs BT, FP, are equal, as was shown in the scholium to proposition 22 of Book III; and since, as BI is to IT, so is FL to LP, on account of the equality both of the lines BI, IT and of FL, LP, the triangles BIT, FLP will be similar [Margin: e. Elements VI.6].) Therefore, *ex aequo*, as KB is to BT, so is MF to FP; and consequently the straight lines KB, KT are proportional to the straight lines MF, MP, since in both cases the proportion is one of equality [Margin: f. Elements I.4]. Now since, as kB is to BT, so is kT to the same BT; and likewise as MF is to FP, so is MP to the same FP; and it was that as kB is to BT, so is MF to FP [Margin: g. Elements V.7]: it will also be that as kT is to BT, so is MP to FP; and, by conversion, as BT is to Tk, so is FP to PM. Therefore, since as Tk is to kB, so is PN[?] to MF, and as kB is to BT, so is MF to FP, and as BT is to Tk, so is FP to PM, as has been shown, the triangles BkT, FMP will have their sides proportional [Margin: h. Elements VI.6[?]] — printed reference-letter/number faint]; and for that reason they will be equiangular, and therefore similar, by the definition. It will be shown in no other way that the remaining triangles enclosing the pyramids ATBVCXDYk, EPFQGRHSM are similar to one another. And these, being equal in number, make the said pyramids similar, by definition 9 of Book XI. Consequently they will be in the triplicate ratio of the corresponding sides BT, FP, by the corollary to proposition 8 of this book.

Now as BT is to FP, so is BI to FL, on account of the similarity of the triangles BIT, FLP; and as BI is to FL, so is BD to FH [Margin: i. Elements V.11]. The pyramid will therefore have to the pyramid the triplicate ratio of the diameters BD, FH. But the ratio of the cone ABCDK to N was also assumed the triplicate of the same diameters. Therefore it will be that as the pyramid ATBVCXDYk is to the pyramid

EPFQGRHSM, so is the cone ABCDk to N. And since the pyramid ATBVCXDYk is less than the cone ABCDk, the part than the whole, the pyramid EPFQGRHSM will also be less than N [Margin: k. Elements V.14] — but it was shown to be greater. Which is absurd. Therefore the magnitude N is not greater than the cone EFGHM.

Let N next be greater than the cone EFGHM. Since, then, it is assumed that the cone ABCDk has to N the triplicate ratio of the diameter BD to the diameter FH, and the pyramid ATBVCXDYk has to the pyramid EPFQGRHSM the triplicate ratio of the same diameters, as we have just shown: it will be that as the cone ABCDk is to N, so is the pyramid ATBVCXDYk to the pyramid EPFQGRHSM; and, by conversion, as N is to the cone ABCDk, so is the pyramid EPFQGRHSM to the pyramid ATBVCXDYk. And since, by the corollary to proposition 8 of this book, the pyramid EPFQGRHSM has to the pyramid ATBVCXDYk the triplicate ratio of the corresponding sides PF to TB — that is, of the diameter FH to the diameter BD — N will also have to the cone ABCDk the triplicate ratio of the diameter FH to the diameter BD. Let it be that as N is to the cone ABCDk, so is the cone EFGHM to the magnitude O. The cone EFGHM will therefore also have to O the triplicate ratio of the diameter FH to the diameter BD. And since N is assumed greater than the cone EFGHk, the cone ABCDk will also be greater than O [Margin: l. Elements V.14]. Consequently the cone EFGHM has to the magnitude O, which is less than the cone ABCDk, the triplicate ratio of the diameter FH to the diameter BD. Which is absurd; for it has been shown that a cone cannot have to a magnitude less than another cone the triplicate of the ratio that the base-diameters have. Therefore the magnitude N is not greater than the cone EFGHM; but neither was it shown to be less; it is therefore equal [Margin: m. Elements V.7]. And so the cone ABCDk has the same ratio to the cone EFGHM as to N. Since, then, the cone ABCDk is assumed to be to N in the triplicate ratio of the diameters BD and FH, it will also be to the cone EFGHM in the triplicate ratio of the same diameters.

Now since cylinders — their triples — obtain the same ratio that the cones have, the cylinder will also have to the cylinder the triplicate ratio of the diameters in the bases [Margin: n. Elements V.15]. This too will be demonstrated in the same way we used for the cones, if only, in place of the cones and pyramids, cylinders and prisms are taken. Similar cones and cylinders, therefore, are in the triplicate ratio of the diameters that are in their bases. Which was to be shown.

SCHOLIUM [to Proposition 12, continued]

[The scholium of Proposition 12 continues from the previous page.]

Now if a larger cone and cylinder are compared with a smaller, it is evident — in the second part of this proposition — that Euclid takes it as demonstrated, in Prop. 8 of this book, that the smaller pyramid has to the larger the triplicate ratio of their homologous sides. This is the very point we noted, in connection with Def. 10 of Book 5, against Federico Commandino [Federico Commandino] and others, who suppose that the greater quantity must always be referred to the lesser in order to obtain a duplicate, triplicate, etc., ratio.

Furthermore, although this proposition may also be extended to similar *scalene* [oblique] cones and cylinders, nevertheless it is here demonstrated only for similar right cones and cylinders, since in the demonstration the axes are assumed to be at right angles to the bases. We shall therefore, by the following method, show it for similar scalene cones and cylinders as well. Let there be similar scalene cones and cylinders whose bases are the circles ABC, DEF, and whose axes are GH, Ik. I say that both cone to cone, and cylinder to cylinder, have the triplicate ratio of diameter to diameter. For conceive, upon the same bases, two right cones and cylinders of the same heights as the scalene ones, whose axes are GL, IM.

Diagram. Two circles side by side, each carrying a horizontal diameter through its center and an axis-construction above it.

- Left circle — center G; horizontal diameter A–G–C; lowest point B. Above the circle, points L (directly over G) and H (to the right) are joined by the segment LH; GL is the vertical (right) axis and GH the oblique axis, so that L, H, G form the right triangle GHL; a line runs from H to C.
- Right circle — center I; horizontal diameter D–I–F; lowest point E. Above, points M (directly over I) and K joined by the segment MK; IM is the vertical axis and IK the oblique axis, forming the triangle IkM; a line runs from K to F.

Let straight lines GH, GL be drawn; likewise Ik, IM, and let planes cut the bases in the straight lines AC, DF, which will be the diameters of the bases. Since, then, the axes GL, IM are at right angles to the bases ABC, DEF, [Margin: o — Elements XI.18] the planes through GH, GL and through IK, IM will also be at right angles to those same bases. [Margin: p — Elements XI.38] And therefore the perpendiculars dropped from H and k to the bases will fall upon AC, DF, the common sections; and accordingly the angles CGH, FIk will be the angles of inclination, which will be equal to one another, since the scalene cones and cylinders are supposed similar. Moreover the angles CGL, FIM are equal, being right angles, by Def. 3 of Book 11. [Margin: q — Elements I.32] The remaining angles HGL, kIM will

therefore also be equal. And since the cones ABCH, ABCL are supposed to be of the same height, the straight line HL, drawn through the vertices of the axes, will be parallel to AC; [Margin: r — Elements I.29] and hence the angle L is a right angle. By the same argument the angle M will be right, since the angles CGL, FIM are right. In just the same way the remaining angles H, K will be equal, since their alternate angles CGH, FIk are equal. The triangles GHL, IkM are therefore equiangular; [Margin: s — Elements VI.4] and accordingly, as GH is to GL, so is Ik to IM; and, by alternation, as GH is to Ik, so is GL to IM. But as the axis GH is to the axis Ik, so is AC, the diameter, to DF, the diameter, because the scalene cones and cylinders are supposed similar. Therefore GL, the axis, will be to IM, the axis, as AC, the diameter, to DF, the diameter; and consequently the right cones and cylinders ABCL, DEFM will be similar, by the definition. [Margin: t — Elements XII.12] They will therefore have the triplicate ratio of their diameters. And since both the cone and cylinder ABCL is equal to the cone and cylinder ABCH (having the same base and height), and likewise the cone and cylinder DEFM is equal to the cone and cylinder DEFk (for the same reason) — as is established by the corollary to Prop. 11 of this book — it follows that as the cone and cylinder ABCL is to the cone and cylinder DEFM, so is the cone and cylinder ABCH to the cone and cylinder DEFk; and hence the ratio of the cone and cylinder ABCH to the cone and cylinder DEFk is likewise the triplicate of that of the diameter AC to the diameter DF. Which was proposed.

[Margin: xi.]

THEOR. 13. PROPOS. 13.

If a cylinder is cut by a plane parallel to the opposite planes, then cylinder will be to cylinder as axis to axis.

Let the cylinder ABCD be cut by the plane GH, parallel to the opposite planes AB, CD, and let this plane cut the axis EF at I. I say that as the cylinder ABHG is to the cylinder GHCD, so is the axis EI to the axis IF. For conceive the cylinder ABCD to be extended in both directions — together with its axis and with the rectangle EC by whose revolution the cylinder was described — produced as far as you please. On the produced axis take any number of segments EK, KL equal to EI itself; likewise any number of segments FM, MN, NO equal to FI. Then through the points I, K, L, M, N, O draw the straight lines IH, KP, LQ, MT, NV, OX, parallel and equal to the straight lines EB, FC; and these, in the revolution of the rectangle EC, will describe the circles GH, PQ, QS, Tα, VZ, XY [α = the Greek letter alpha, here a point-label], parallel and equal to the circles AB, CD, because of the equality of the radii, which are always carried around equidistant from one another. And

therefore, by definition, the cylinders SP, PA, AH, HD, DT, TZ, ZX will result, composing the whole cylinder SQXY.

Diagram. A cylinder drawn in side view along a horizontal axis, its equal circular cross-sections shown as tall vertical (vesica-shaped) ovals set side by side; each section is named by the endpoints of its vertical diameter.

- Top edge, left to right: S, R, A, G, D, α , Z, V.
- Bottom edge, left to right: Q, P, B, H, C, T, V, X.
- Along the axis / section centers, left to right: L, K, E, I, F, M, N, O.

The central section (base) is AB (A on the top edge, B on the bottom), with the cutting circle GH; the successive sections toward S are PQ, QS, and toward X are T α , VZ, XY. [Two of the edge labels appear as "V" (top and bottom); transcribed as read.]

Now since the cylinders SP, PA, AH — standing on the equal bases QS, PR, BA and under the equal heights KL, EK, IE — are equal, and likewise the cylinders XZ, ZT, TD, DH — standing on the equal bases XY, VZ, T α , CD and under the equal heights NO, MN, FM, IF — are equal (by the corollary to Prop. 11 of this book): the cylinder SH will be the same multiple of the cylinder AH as the axis IL is of the axis IE; and likewise the cylinder XG will be the same multiple of the cylinder CG as the axis IO is of the axis IF. And since, if the axis IL (a multiple of IE, the first magnitude) is equal to the axis IO (a multiple of the axis IF, the second magnitude), then the cylinder SH (a multiple of the cylinder AH, the third magnitude) is likewise equal to the cylinder XG (a multiple of the cylinder CG, the fourth magnitude) — as is clear from Prop. 11 of this book; while if the axis is greater than the axis, the cylinder too is greater than the cylinder, and if less, less, in whatever multiplication this happens — it follows, by Def. 6 of Book 5, that as the axis IE, the first magnitude, is to the axis IF, the second magnitude, so is the cylinder AH, the third magnitude, to the cylinder CG, the fourth magnitude. If therefore a cylinder is cut by a plane parallel to the opposite planes, then cylinder will be to cylinder as axis to axis. Which was to be demonstrated.

SCHOLIUM [to Proposition 13]

Although Euclid demonstrates this proposition only for the right cylinder, nevertheless you will readily adapt his demonstration to the scalene cylinder, provided you employ the description of the scalene cylinder, just as in Euclid's demonstration the description of the right cylinder was assumed; so that, just as in right cylinders [printed *conis* — "cones"; recte: *cylindris*] a rectangle is carried

around its stationary side, so too in scalene cylinders [printed *conis*; recte: *cylindris*] the radii LS, KR, EA, etc., are carried around, always equidistant, about the centers L, K, E, etc., together with the straight line SY joining the radii. For it is in this way that cylinders are always described, as is established from what Serenus [Serenus of Antinoöpolis] writes in Book 1 of *On the Section of the Cylinder*.

Diagram. The same side-view cylinder as before, its equal circular cross-sections drawn as tall vertical ovals set side by side, each named by the endpoints of its vertical diameter.

- Top edge, left to right: S, R, A, G, D, α , Z, V.
- Bottom edge, left to right: Q, P, B, H, C, T, V, X.
- Along the axis / section centers, left to right: L, K, E, I, F, M, N, O.

[Margin: xi.]

THEOR. 14. PROPOS. 14.

Cones and cylinders standing on equal bases are to one another as their heights.

Let there be, on the equal bases AB, CD, two cones ABE, CDF and two cylinders ABGH, CDIK, whose axes — or heights (for in right cones and cylinders the axes are themselves the heights) — are LE, ME. I say that cone ABE is to cone CDF, and cylinder ABGH to cylinder CDIK, as the height LE is to the height ME. For let the cylinder ABGH be extended on the side of GH, together with its axis LE and the rectangle AG; and let the axis EN be cut off equal to the axis ME, and about the center N let a circle OP be conceived, equal and parallel to the circle GH, so that a cylinder GHOP is formed, of the same height as the cylinder CDIK. Since, then, the cylinders HP, CI, having equal bases and heights, are equal (by the corollary to Prop. 11 of this book), [Margin: a — Elements V.7] the cylinder AG will have the same ratio to each of them. [Margin: b — Elements XII.13] But cylinder AG is to cylinder HP as the axis, or height, LE is to the axis, or height, EN — that is, to MF, which is equal to it. Therefore cylinder AG will be to cylinder CI also as the height LE to the height MF.

[Margin: c — Elements XII.10] And since the cones ABE, CDF are the third parts of the cylinders AG, CI, [Margin: d — Elements V.15] they will have the same ratio as the cylinders; and accordingly cone ABE will also be to cone CDF as the height LE to the height MF. Cones and cylinders, therefore, standing on equal bases, are to one another as their heights. Which was to be shown.

Diagram. Two upright solids, each a right cylinder with an inscribed right cone. On the left a tall solid, on the right a shorter one.

- Left solid — top circle O–N–P (N the center); middle circle H–E–G (E the center); bottom circle (base) A–L–B (L the center). The cone has its apex at E and its base AB (lines from E to A and to B).
- Right solid — top circle K–F–I (F the center); bottom circle (base) C–M–D (M the center). The cone has its apex at F and its base CD.

SCHOLIUM [to Proposition 14]

We shall demonstrate that this same result holds for scalene cones and cylinders in the following way. Let there be, on the equal bases AB, CD, the scalene cones ABE, CDF and the scalene cylinders ABGH, CDIK, whose heights are LM, NO. I say that cone ABE is to cone CDF, and cylinder ABGH to cylinder CDIK, as the height LM is to the height NO. For upon the base AB let a right cylinder ABPQ be constructed, under the height LM; likewise upon the base CD a cylinder CDRS, under the height NO.

Diagram. Two oblique (scalene) cylinder-and-cone assemblies, drawn slanted with construction lines converging to the cone apices.

- Left assembly — top: Q, M, P; an intermediate slanted circle H, E, G; base A, L, B. (Right cylinder ABPQ and scalene cylinder ABGH share the base AB; the cone apex is E.)
- Right assembly — top: S, O, R and K, F, I; base C, N, D (N the center). (Right cylinder CDRS and scalene cylinder CDIK share the base CD; the cone apex is F.)

[The crowded, foxed vertex-labels of these two oblique solids]

[Margin: c — Elements XII.14] Since, then, the right cylinder ABPQ is to the right cylinder CDRS as the height LM to the height NO; and since the cylinder ABGH is equal to the cylinder ABPQ, and likewise the cylinder CDIK is equal to the cylinder CDRS (by the corollary to Prop. 11 of this book): the cylinder ABGH will also be to the cylinder CDIK as the height LM to the height NO. Which was proposed.

[Margin: f — Elements XII.10] And since the cones, [Margin: g — Elements V.15] being the third parts of the cylinders, have the same ratio as the cylinders, cone ABE will also be to cone CDF as the height LM to the height NO. This, however, can be confirmed by the same argument that we used for the cylinders, as is

evident, if upon the bases AB, CD there are made right cones ABM, CDO, of the same heights as the cylinders ABPQ, CDRS.

The same conclusion will follow even if one of the cones and cylinders — namely cone ABE and cylinder ABGH — is scalene, while the other — namely cone CDO and cylinder CDRS — is right. For since the scalene cylinder ABGH is equal to the right cylinder ABPQ, and the right cylinder ABPQ is to the right cylinder CDRS as the height LM to the height NO (as Euclid demonstrated): the scalene cylinder ABGK [recte: ABGH] will also be to the right cylinder CDRS as the height LM to the height NO. Which was proposed.

[Margin: h — Elements V.15] And since the cones have the same ratio as the cylinders, [Margin: i — Elements XII.10] the former being the third parts of the latter: the scalene cone ABE will also be to the right cone CDO as the height LM to the height NO. This too will be shown by the same reasoning we used for the cylinders, as is manifest.

The same proposition holds also for prisms, parallelepipeds, and pyramids set upon equal bases. For let there be, upon the equal bases ABC, DEFG, the prisms ABCHIK, DEFGLMNO, and pyramids under the same heights. I say that

prism is to prism, and pyramid to pyramid, as height to height. For let the lines AI, CH, BK, standing upon the base ABC of the prism ABCHIK, be perpendicular to it, so that BK is the height of the prism ABCHIK. Then, the straight lines AI, CH, BK being produced, take IQ, HR, KP equal to the height of the prism EL; and, the straight lines PQ, QR, RP being drawn, let the prism HIKPQR be completed, of the same height as the prism EL. The prisms HIKPQR, EL, having equal bases and heights, will be equal to one another, by the corollary 2 of Prop. 7 of this book.

[Margin: k — Elements V.7] And therefore the prism ABCHIK will have the same ratio to each of them. And since, by the scholium of Prop. 25 of Book 11, the prism ABCHIK is to the prism HIKPQR as the plane BI to the plane KQ; [Margin: l — Elements VI.1] and as the plane BI is to the plane KQ, so is the straight line BK to KP: the prism ABCHIK will be to the prism HIKPQR — that is, to the prism EL — as BK, the height of the prism ABCHIK, is to KP, the height of the prism HIKPQR, that is, of the prism EL. Which was proposed.

Diagram. Two solids side by side: on the left a triangular prism surmounted by a pyramid; on the right a parallelepiped (box).

- Left solid — apex Q at the top; upper vertices P (left) and R (right); a central point I; the middle level K (left) and H (right); lower vertex A (front); base

vertices B (left) and C (right). This is the prism ABCHIK with the pyramid HIKPQR built upon it.

- Right solid (box) — top face M (left), L (right); N (front-left), O (front-right); D (center-front); base E (left), F (center), G (right). This is the prism/parallelepiped DEFGLMNO ("EL").

But if the lines AI, CH, BK are not perpendicular to the base ABC, then upon the base ABC one must construct another prism whose standing edges are perpendicular to the base and equal in height to the prism ABCHIK. For since, by the 2nd corollary of Prop. 7 of this book, these two prisms — having the same height and base — are equal, and since the constructed prism is to the prism EL as the height of the one to the height of the other: the prism ABCHIK will also be to the prism EL as the height of the one to the height of the other.

[Margin: m — Elements V.15] And since the pyramids have the same ratio to the prisms, [Margin: n — Elements XII.10] because they are the third parts of them: it is evident that pyramid is likewise to pyramid as height to height.

Exactly the same account is to be given of parallelepipeds, since parallelepipeds too are comprehended under the name of prisms, as has been said; and for this reason the same demonstration can be adapted to them.

All these results will be demonstrated in nearly the same way of cones and cylinders, and also of pyramids and prisms having the same base.

All these, moreover, can readily be converted, in this way:

Cones and cylinders, whether right or scalene; likewise prisms, parallelepipeds, and pyramids — if they have the same ratio as their heights, will have equal bases.

For otherwise a part would be equal to the whole, as was shown in the converse of Prop. 31 of Book 11.

[Margin: xii.]

THEOR. 15. PROPOS. 15.

In equal cones and cylinders the bases and heights are reciprocally proportional; and those cones and cylinders whose bases and heights are reciprocally proportional are equal.

Let there be equal cones ABC, DEF [printed *ABCD*, *DEF* — the first apparently for *ABC*, *DEF*] and equal cylinders ABGH, DEIK, whose bases are AB, DE and whose

axes or heights are LC, MF. I say that the bases and heights are reciprocally proportional — that is, that as AB is to DE, so is MF to LC. In the case of the cylinders the proposition will be shown thus. If the heights LC, MF are equal, then, since the cylinders are also supposed equal, the bases too will be equal, by the corollary to Prop. 11 of this book. Hence, as the base AB is to the equal base DE, so is the height MF to the equal height LC. And accordingly the bases and heights are reciprocally proportional.

Diagram. Two upright solids side by side, each a cylinder with an inscribed cone; the right-hand one carries a horizontal cutting-circle.

- Left solid — top circle H–C–G (C the center and cone apex); bottom circle (base) A–L–B (L the center); axis LC. Cylinder ABGH with inscribed cone ABC.
- Right solid — top circle K–F–I (F the center and cone apex); an intermediate cutting-circle through O and N (the plane ON, parallel to the base); bottom circle (base) D–M–E (M the center); axis MF. Cylinder DEIK with inscribed cone DEF, and the sub-cylinders DO, OK produced by the cutting-plane.

[Some interior vertex-labels of the right-hand solid (the cutting-circle points O, N) are crowded]

But if the heights LC, MF are unequal, let MF be the greater, and from it cut off MN equal to LC; and through N let a plane ON be drawn parallel to the base DE, as we taught in the scholium of Prop. 15 of Book 11, so that two cylinders DO, OK are formed. Since, then, the cylinders ABGH, DEIK are supposed equal, [Margin: a — Elements V.7] it follows that as the cylinder ABGH is to the cylinder DO, so is the cylinder DEIK to the same cylinder DO. [Margin: b — Elements XII.11] But as the cylinder ABGH is to the cylinder DO, so is the base AB to the base DE, since the heights are equal; [Margin: c — Elements XII.14] and likewise as the cylinder DEIK is to the cylinder DO, so is the height MF to the height MN, since the bases are equal — indeed one and the same, DE. Therefore it will also follow that as the base AB is to the base DE, so is the height MF to the height MN, that is, to LC, which is equal to it. And accordingly the bases and heights are reciprocally proportional.

In the case of cones we shall conclude the proposition thus. If the cones ABC, DEF are equal, then the cylinders ABGH, DEIK will also be equal, [Margin: d — Elements XII.10] since the cones are the third parts of the cylinders. Hence, as was shown, from the equality of the cylinders it will follow that the bases and heights are reciprocally proportional; and accordingly, from the equality of the

cones as well, it will follow that the bases and heights are reciprocally proportional. This, however, can be demonstrated in exactly the same way that we used for the cylinders, if only two cones are set up under the heights MN, NF, as in the figure.

But now let the bases and heights be reciprocally proportional. I say that the cones and cylinders are equal. This indeed will be confirmed for the cylinders by the following reasoning. If the heights LC, MF are equal, then, since as the base AB is to the base DE so is the height MF to the equal height LC, the bases AB, DE will also be equal; and accordingly the cylinders, standing on the equal bases AB, DE and under the equal heights LC, MF, will be equal, by the corollary to Prop. 11 of this book.

Euclid, *Elements*, Book XII (Clavius's commentary)

Proposition 15 (continued) — converse, case of unequal heights

**

But if the heights are unequal, let the construction be made as before. Since, then, it is assumed that as base AB is to base DE, so is the height MF to the height LC — that is, to MN, which is equal to LC — [Margin: e — XII.11] while, because the heights are equal, as base AB is to base DE, so is cylinder ABGH to cylinder DO; [Margin: f — XII.14] and likewise, because the bases are equal, as the height MF is to the height MN, so is cylinder DEIK to cylinder DO: it will follow that as cylinder ABGH is to cylinder DO, so is cylinder DEIK to that same cylinder DO. [Margin: g — V.9] Therefore cylinder ABGH will be equal to cylinder DEIK.

But in the case of cones the demonstration will run as follows. If in the cones ABC, DEF the bases and heights are reciprocally proportional, then the bases and heights of the cylinders ABGH, DEIK will likewise be reciprocally proportional, since the bases, and the heights, of the cones and of the cylinders are the same. For this reason, as was shown, the cylinders — and therefore the cones, which are their third parts — will be equal. It can nevertheless be demonstrated in the same way that the cones are equal, by which we showed the cylinders to be equal. Therefore in equal cones and cylinders the bases and heights are reciprocally proportional, and so on. Which was to be demonstrated.

Diagram. Two solid figures (cone-within-cylinder) drawn side by side, illustrating Proposition 15.

- Left solid: a cylinder with lower circle lettered **A** (left), **L** (front/bottom), **B** (right), and upper circle **H** (left), **C** (top), **G** (right); a cone with apex at **C** and generating lines drawn to the base points **A**, **L**, **B**.
- Right solid: a cylinder with lower circle **D** (left), **M** (front/bottom), **E** (right), upper circle **K** (left), **F** (top), **I** (right), and a mid-level circle lettered **N**; a cone with apex at **F** and generating lines to the base points **D**, **M**, **E**, with **O** marked on the right of the middle circle.

Scholium

It will not be difficult to show the same thing for scalene (oblique) cones and cylinders. For if scalene cones and cylinders are equal, then the right cones and cylinders that have the same bases and heights as they do will also be equal, by the corollary of Proposition 11 of this book. Hence, as has been shown, their bases and heights will be reciprocally proportional. And conversely, if the bases and heights of scalene cones and cylinders are reciprocally proportional, then the bases and heights of the right cones and cylinders will likewise be reciprocally proportional, provided the bases and heights of the right and of the scalene solids are the same. Hence, as has been demonstrated, the right cones and cylinders will be equal; and consequently the scalene cones and cylinders, being equal to the right ones, will — by the corollary of Proposition 11 of this book — also be equal to one another.

The same will easily be concluded even if one of the cones or cylinders be right and the other scalene, as is evident from what we taught in the scholium of Proposition 14 of this book.

PROBL. 1. PROPOS. 16.

[Margin: xiiij.]

Given two circles about the same centre, to inscribe in the greater circle an equilateral polygon, having an even number of sides, that does not touch the lesser circle.

Let **ABC** and **DE** be two circles about the same centre **F**, and let it be required to inscribe in the greater, **ABC**, an equilateral polygon whose sides are even in number and which does not touch the lesser circle **DE**. Let the straight line **AC** be extended through the centre **F**, cutting the circle **DE** at the point **E**; and through **E** let **GH** be drawn perpendicular to **AC**. This perpendicular will touch the circle **DE**

at E, by the corollary of Proposition 16 of Book 3. Now since the arc AGC is greater than the arc GC, if from AGC there be taken away the half AB, and from the remainder BC the half BI, and from the remainder IC the half Ik, and so on in succession, [Margin: a — X.1] there will at length be left an arc smaller than CG. Let arc Ck now be smaller than arc CG, and let the straight line Ck be drawn as its chord. I say that the straight line Ck is one side of the polygon to be inscribed.

For if the arc BI be divided into parts equal in number and magnitude to the parts of arc CI; and the quadrant AB be divided into as many equal parts as the quadrant BC has been divided into; and likewise the semicircle AHC into as many parts as the semicircle ABC contains; and if then straight lines be drawn as chords under all the arcs, [Margin: b — III.29] these chords will be equal to the straight line Ck, because they subtend arcs equal to arc Ck: there will then be described in the circle ABC a polygon that is both equilateral and of an even number of sides.

That this polygon does not touch the lesser circle DE is shown thus. From k let a perpendicular kL be dropped to AC, cutting AC at M. Since, then, the angles GEM and kME are right, [Margin: c — I.29] the straight lines GH and kL will be parallel. Hence, since the straight line GH touches the circle DE at the single point E, the straight line kL will lie wholly outside that circle and will never meet it, because it never meets the line GH. Much less, therefore, will the straight line Ck — which is farther from the circle DE than kL is — touch the circle DE. And for this reason neither will the other sides of the inscribed polygon touch the circle DE, since they are equal to the side Ck [Margin: d — III.14] and are therefore equally distant with Ck from the centre F. Thus, given two circles about the same centre, [an equilateral polygon of an even number of sides has been inscribed] in the greater circle, and so on. Which was to be done.

Diagram. Two concentric circles with a diameter drawn through the common centre, illustrating Proposition 16.

- A — left end of the horizontal diameter (on the greater circle).
- F — the common centre.
- E — the point where the diameter meets the lesser circle (on the right side); the tangent GH is drawn through E.
- C — right end of the diameter (on the greater circle) [partly off the tile].
- B — top of the greater circle.
- D — a point on the upper part of the lesser circle.
- M — foot of the perpendicular kL on the diameter.
- L — lower-right, on the perpendicular kL.

- **H** — lower part of the figure.
- Further points **G, I, k** lie around the periphery of the greater circle; several of these labels are faint under foxing. [?]

Corollarium

From this it is manifest that if, from the end of a side of the inscribed polygon which meets the diameter, a perpendicular be drawn to the diameter, this perpendicular can in no way touch the lesser circle, but falls wholly outside it. For of this kind is the line **kL**, which — being drawn from the end-point **k** of the side **Ck** (the side that meets the diameter **AC**) perpendicular to the diameter **AC** — has been shown not to touch the circle **DE**.

[Margin: kiv.]

PROBL. 2. PROPOS. 17.

Given two spheres about the same centre, to inscribe in the greater sphere a solid polyhedron that does not touch the surface of the lesser sphere.

Let **ABCD** and **EFGH** be two spheres about the same centre **I**, and let it be required to inscribe in the greater, **ABCD**, a solid polyhedron — that is, a many-sided solid — that does not touch the lesser sphere **EFGH**. Let both spheres be cut by some plane through the centre, and let the common sections made in the spheres be the planes **ABCD** and **EFGH**. These will be circles — by the description of the sphere — having the same centre **I** as the spheres. For the semicircles by whose revolution the spheres are described, when carried round, coincide with the sections **ABCD**, **EFGH**; hence the said sections will be circles. Or, more surely: because all the straight lines falling from **I** to the peripheries of the sections are equal — being drawn from the centre of the spheres to their surface — the sections themselves will be circles, by the definition of a circle.

[Margin: a — XII.16] In these circles let the diameters **AC**, **BD** be drawn, cutting one another at right angles at the centre **I**, so that **AB**, **BC**, **CD**, **DA** are quadrants, and so on. Next, in the greater circle **ABCD** let a polygon be inscribed that does not touch the lesser circle **EFGH**. That everything may be more easily demonstrated, let this be effected in the following manner. From **G** let **GF** be drawn perpendicular to **EG**, as far as the circumference of the circle **ABCD**; this perpendicular will touch the circle **EFGH** at **G**, by the corollary of Proposition 16 of Book 3. *[Margin: b — IV.1]* And equal to the straight line **GF** let a straight line **Aε** be fitted into the circle **ABCD**. *[Margin: c — I.19]* Now if a straight line be

imagined drawn as a chord under the arc CF , so as to form the triangle GCF , the side CF — being opposite the greater angle, namely the right angle — is greater than the side GF , which is opposite the lesser angle, namely the acute one. Hence the straight line CF will also be greater than the straight line $A\varepsilon$, and consequently the arc CF will be greater than the arc $A\varepsilon$, as is established from the scholium of Proposition 28 of Book 3. Let then an arc $C\delta$ be cut off equal to the arc $A\varepsilon$.

[Margin: d — X.1] And if from the quadrant CD the half DL be taken away, and from the remainder CL the half LK , and so on in succession, there will at length be left an arc smaller than the arc $C\delta$, that is, than the arc $A\varepsilon$. Let arc CK now be the smaller one; and the straight line CK , drawn as its chord, will be smaller than the straight line $A\varepsilon$ — that is, than GF — by the scholium of Proposition 29 of Book 3. I say, then, that the straight line CK [printed: GK ; recte CK] is one side of the equilateral polygon to be inscribed. For since the straight line subtending the arc $C\delta$ — which is less than the arc CF — does not touch the circle $EFGH$, as is clear from the demonstration of the preceding proposition, much less will the straight line CK , subtending an arc smaller than the arc $C\delta$, [Margin: e — XI.12] touch that same circle.

Again, the diameter KN having been drawn, [Margin: f — XI.18] let there be erected from the centre I a perpendicular IO to the planes of the circles $ABCD$, $EFGH$, meeting the surface of the greater sphere at O ; and through the straight lines OI , AC and OI , KN let planes be drawn, [Margin: g — schol. III.21] which will stand at right angles to the circle $ABCD$ and will produce, as common sections, circles — as has already been said — of which the semicircles are AOC , NOK . And since the angles OIC , OIK are right, by Definition 3 of Book 11, [Margin: h — III.29] OC and OK will be quadrants; and moreover, since the circles $ABCD$, AOC , NOK are equal — because their diameters are also diameters of the greater sphere — the quadrants CD , OC , OK will likewise be equal. If, then, the arc DL be distributed into as many equal parts as the arc CL was divided into, and the quadrants OC , OK into arcs equal in number and magnitude to the arcs of the quadrant CD , [Margin: i — XI.38 [?]] the straight lines subtended under all these equal arcs — namely CK , KL , LM , MD ; CP , PQ , QR , RO ; KS , ST , TV , VO — will be equal. And when the straight lines PS , QT , RV have been joined, let perpendiculars PX , SY be dropped from P and S to the plane of the circle $ABCD$, [Margin: k — XI.6] which will fall on the common sections AC , NK ; and these perpendiculars will be parallel to one another.

Diagram. A large schematic of two concentric spheres cut by great circles, showing the polyhedron inscribed in the greater sphere (Proposition 17). The same woodcut is reproduced on the facing page. The figure is crowded, foxed, and at the resolution floor; the labels below are those legible on the scan at high magnification, with uncertain ones flagged.

- **A** — left end of the horizontal diameter AC (great circle ABCD).
- **C** — right end of the horizontal diameter AC.
- **I** — the common centre of the spheres.
- **O** — top, the pole where perpendicular IO meets the greater sphere (on great circle AOC).
- **N** — upper-left, on the great circle (diameter KN).
- **B** — top region of the great circle ABCD [there appear to be two labels resembling "B", one near V at upper left and one near T in the middle — at least one is uncertain]. [?]
- **D** — lower-left, on the great circle.
- **M** — bottom-left, on the quadrant arc.
- **F** — a point on an inner (lesser-sphere) circle, upper-middle-left.
- **G, H** — points on the lesser circle EFGH (lower-middle region); **H** below centre, **G** faint. [?]
- **R, Q, P** — successive division points on the arc from O down to C (arcs RO, QR, PQ, CP).
- **V, T, S** — successive division points on the meridian arc from O down to K (arcs VO, TV, ST, KS).
- **K** — lower-right division point of the quadrant CD (arc CK); with **Y** beside it (foot of a perpendicular).
- **L** — lower division point (arcs KL, LM).
- **X** — foot of a perpendicular on AC, near C.
- **α** (alpha) — near X/C, foot of a perpendicular.
- **γ** (gamma), **δ** (delta), **ε** (epsilon) — auxiliary points near the lower-right and left periphery.

Proposition 17 (continued)

Since, then, in the triangles PCX, SKY the angles PXC, SYK are right, by Definition 3 of Book 11, [Margin: I — III.27] and the angles PCX, SKY are equal — because the arcs AOP, NOS on which they stand are equal (for if from the equal semicircles AOC, NOK the equal arcs CP, KS be taken away, the remaining arcs AOP, NOS will

also be equal) — the two angles PCX, PXC of triangle PCX will be equal to the two angles SKY, SYK of triangle SKY. And the sides PC, SK, opposite the right angles, are equal. [Margin: m — I.26] Therefore the remaining sides PX, XC will be equal to the remaining sides SY, YK.

Hence, since the straight lines PX and SY [text prints "PY"] are equal and parallel, if the straight line XY be joined, [Margin: n — I.33] PS and XY will also be equal and parallel to one another. [Margin: o — VI.2] But since the straight lines CK, XY are also parallel — because the sides IC, IK are cut proportionally (for if from the equal radii IC, IK the equal straight lines CX, KY be taken away, IX and IY will remain equal; and hence, as IX is to XC, so will IY be to YK) — [Margin: p — 9. duodecimi (?) — the parallels reasoning points to XI.9] the straight lines PS, CK will also be parallel to one another, since each is parallel to XY; [Margin: q — XI.7] and therefore the straight lines CP, KS that join them will lie in the same plane with them. The whole quadrilateral CKSP, therefore, will lie in one plane.

And if from Q and T perpendiculars be dropped to the plane of the circle ABCD, and the straight lines QC, TK be joined, we shall show in like manner that CK, QT are parallel, and further that PS, QT are parallel to one another (since they are both parallel to CK), and that the whole quadrilateral PSTQ lies in one plane. By the same reasoning the quadrilateral QTVR will lie in one plane; [Margin: r — 12. undecimi (?) — the "triangle in one plane" reasoning points to XI.2] and the triangle RVO too is in a plane. If, then, the same construction be carried out upon the remaining sides KL, LM, MD — namely by drawing the quadrants OL, MO, OD — and likewise in the other three quarters and in the remaining hemisphere, so that the whole greater sphere is filled with quadrilaterals and triangles similar to those constructed between the quadrants OC, OK upon the side CK, there will be inscribed in the greater sphere a solid polyhedron bounded by the said quadrilaterals and triangles. This, then, I say, does not touch the lesser sphere EFGH.

Diagram. The identical woodcut of the two concentric spheres and the inscribed polyhedron is reproduced on this page (see fig-p542-1 for the full label list). The reproduction is equally crowded and foxed; the same labels are readable (O at the top, A and C at the ends of the horizontal diameter, I at the centre, N upper-left, and the division points R, Q, P, V, T, S, K, L, M, D around the periphery, with the auxiliary Greek points α , γ , δ and points F, G, H, X, Y). More than two labels remain uncertain

Now let a perpendicular IZ be drawn from I to the plane CKSP, and let the straight lines ZC, ZK be joined. That the perpendicular IZ falls within the quadrilateral

CKSP we shall show in the following scholium. Since, then, by Definition 3 of Book 11 the angles IZC, IZK are right, [Margin: s — I.47] the square on the straight line IC will be equal to the squares on IZ, ZC, and the square on IK equal to the squares on IZ, ZK. Since, then, the squares on the equal straight lines IC, IK are equal, the squares on IZ, ZC will also be equal to the squares on IZ, ZK; and hence, the common square on IZ being taken away, the remaining squares on ZC, ZK will be equal, and therefore the straight lines ZC, ZK themselves are equal. In like manner we shall show that the straight lines drawn from Z to PS are equal both to one another and to the straight lines ZC, ZK. Hence a circle described from Z at the distance ZC will pass through the four points C, K, S, P. And by the same reasoning we shall demonstrate that circles can be described about the remaining quadrilaterals PSTQ, QTVR and the triangle RVO. And since, as we shall show later, the angle CZK is obtuse, [Margin: t — II.12] the square on the straight line CK will be greater than the squares on ZC, ZK; and therefore, since these squares are equal, the square on CK will be greater than twice the square on ZC.

Now let a perpendicular $K\alpha$ be drawn from K to the straight line AC. Since, then, AC is double AI, and $A\alpha$ is greater than AI, AC will be less than double $A\alpha$. For which reason, since [Margin: u — VI.1] as AC is to $A\alpha$, so is the rectangle contained by AC, αC to the rectangle contained by $A\alpha$, αC — because the bases of these rectangles are AC, $A\alpha$ and the height αC is the same — the rectangle contained by AC, αC will also be less than double the rectangle contained by $A\alpha$, αC . [Margin: x — VI.17] But the rectangle contained by AC, αC is equal to the square on the straight line CK, and the rectangle contained by $A\alpha$, αC is equal to the square on the straight line $K\alpha$; because CK is a mean proportional between AC and αC , and $K\alpha$ a mean proportional between $A\alpha$ and αC , by the corollary of Proposition 8 of Book 6. (For if the straight line...

(Continuation of the demonstration of Book XII, Proposition 17 — to inscribe in the greater of two concentric spheres a solid polyhedron that does not touch the lesser.)

(if the straight line AK were drawn, a right triangle ACK would be formed.) The square on CK, therefore, will also be less than twice the square on $K\alpha$. And since the square on CK has been shown to be greater than twice the square on ZC, the square on $K\alpha$ will be greater than the square on ZC. [Margin: y — 47.pri. (Elements I.47)] Now the square on IC equals the squares on IZ and ZC together, and the square on IK equals the squares on $I\alpha$ and αK together; and since the squares on the equal lines IC and IK are themselves equal, the squares on IZ and ZC together will also equal the squares on $I\alpha$ and αK together. If, then, from these

we take away the greater square — namely that on αK — and from the others the smaller — namely that on ZC — the remaining square on IZ will be greater than the remaining square on $I\alpha$, and therefore the line IZ is greater than the line $I\alpha$. Consequently, since the point α does not touch the smaller sphere $EFGH$ — because, by the corollary of the preceding proposition, the whole line $K\alpha$ lies outside that sphere — still less will the point Z , which lies farther off, touch that same sphere. And accordingly, since all the other points of the plane $CKSP$ lie farther from the sphere $EFGH$ than the point Z does, as we shall show shortly, the plane $CKSP$ will not touch the sphere $EFGH$.

But we may show more readily, almost from the very construction of the figure, that the plane $CKSP$ does not touch the smaller sphere $EFGH$, provided the line $I\gamma$ is first drawn, in this way. Since it was shown from the construction that the line CK is less than the line $C\gamma$ [Margin: z — 29.pri. (Elements I.29 [?] — printed digit ambiguous, possibly I.19)] — and CK is greater than ZC , because the angle CZK is obtuse, as will presently be demonstrated — $C\gamma$ will be much greater than ZC , and therefore the square on $C\gamma$ is greater than the square on ZC . [Margin: a — 47.pri. (Elements I.47)] Now since the square on $I\gamma$ equals the squares on IG and $C\gamma$ together, and the square on IC equals the squares on IZ and ZC together, and the squares on the equal lines $I\gamma$ and IC are themselves equal, the squares on IG and $C\gamma$ together will also equal the squares on IZ and ZC together. Taking away, then, on the one side the square on $C\gamma$ and on the other the square on ZC , the square on IG will be left less than the square on IZ , and therefore the line IG is less than IZ . For this reason, since IG is the semidiameter of the smaller sphere $EFGH$, the point Z will lie outside that same sphere; and hence, as before, the plane $CKSP$ will in no way touch the sphere $EFGH$.

Let the perpendicular $I\beta$ be drawn once more from I to the plane $PSTQ$; then β will be the center of the circle described about $PSTQ$, as has been demonstrated. And when the lines βP and IP are joined, since the angle $I\beta P$ is right, by definition 3 of Book 11, [Margin: b — 47.pri. (Elements I.47)] the square on IP will equal the squares on $I\beta$ and βP together. Now the square on IC also — which equals the square on IP , because the lines IC and IP are equal — equals the squares on IZ and ZC together; so the squares on $I\beta$ and βP together will equal the squares on IZ and ZC together. But the square on ZC is greater than the square on βP , because the line ZC is also greater than the line βP , as we shall show later. The remaining square on $I\beta$, therefore, will be greater than the remaining square on IZ , and hence the line $I\beta$ is greater than the line IZ . And accordingly the point β will lie even farther outside the sphere $EFGH$ than the point Z does; and therefore the plane $PSTQ$ will touch the larger sphere $EFGH$ even less than $CKSP$ does. In the

same way we shall demonstrate that the remaining planes cannot touch the said sphere either. Therefore, with two spheres existing about the same center, we have inscribed in the larger sphere a solid polyhedron that does not touch the surface of the smaller sphere. Which was to be done.

COROLLARIUM.

From what has been demonstrated it is manifest that, if in any other sphere a solid polyhedron similar to the aforesaid solid polyhedron be described, the ratio of the polyhedron in the one sphere to the polyhedron in the other sphere is the triplicate of the ratio that the diameters of the spheres have. For if from the centers of the spheres straight lines are drawn to all the angles of the bases of the said polyhedra, the polyhedra will be divided into pyramids equal in number and similar, whose homologous sides are the semidiameters of the spheres — as is clear if the smaller of these spheres is understood to be described within the larger about the same center. For the straight lines drawn from the centers to the angles of the bases will coincide with one another, because of the similarity of the bases, and therefore the pyramids will be made similar. Hence, since each pyramid in the one sphere has to each pyramid similar to it in the other sphere the triplicate ratio of the homologous sides — that is, of the semidiameters of the spheres, as is clear from the corollary of proposition 8 of this book — then, as one pyramid is to one pyramid, so are all the pyramids together (that is, the solid polyhedron composed of them) to all the pyramids together (that is, to the solid polyhedron constituted of them). The polyhedron of the one sphere, therefore, will also have to the polyhedron of the other sphere the triplicate ratio of the semidiameters, and thus of the diameters of the spheres, [Margin: c — 15.quin. (Elements V.15)] since the semidiameters and the diameters have the same ratio.

SCHOLIVM II.

Since, to keep the demonstration from becoming too long, certain things were assumed in it as true which nevertheless have not yet been demonstrated, we shall now demonstrate them briefly.

First, then, it must be shown that the point Z falls within the quadrilateral CKSP, and that the angle CZK within the quadrilateral CKSP is obtuse. To do this more conveniently, let a circle be described about the said quadrilateral from the center Z. Since, then, in the upper figure, as IK is to κC , so is IT to TX — because, by the corollary of proposition 4 of Book 6, the triangles ICK and IXT are similar — and since IK is greater than IT, [Margin: d — 14.quin. (Elements V.14)] KC will also be greater than TX. And since TX has been shown equal to SP, KC will also be

greater than SP; and therefore in this figure the arc CK will be greater than the arc SP, by the scholium of proposition 28 of Book 3. [Margin: e — 28.ter. (Elements III.28)] Hence, since the arcs CP and KS are equal to the arc CK — because the lines CP and KS were also shown equal to the line KC, for they are subtended by equal arcs of circles, as is clear from the construction of the upper figure — the arcs CP and KS will also be greater than the arc PS. And for that reason each of the arcs CK, CP, KS will exceed a quadrant of the circle CKSP, and will be surpassed by a semicircle; and accordingly the much greater segment SP will be less than a semicircle. From this it follows that the center Z is not in those segments, but outside them — namely, within the quadrilateral CKSP. By the same reasoning we shall show that the perpendiculars dropped from I to the planes of the other quadrilaterals — such as $\kappa\beta$ — fall within those quadrilaterals; and likewise that the perpendicular drawn from I to the triangle ORV falls within it. Since, then, the arc CK is greater than a quadrant, the angle CZK will be obtuse — that is, greater than a right angle — because a quadrant of the circle is subtended by a right angle at the center, as is clear from the scholium of proposition 27 of Book 3.

Diagram. A circle circumscribing the quadrilateral CKSP. The upper vertices S (left) and P (right) and the lower vertices K (left) and C (right) lie on the circle; the center Z is marked near the middle (with a monogram-like Z), and straight lines run from Z to K and to C, together with the chords forming the quadrilateral. The figure illustrates that the center Z lies within CKSP and that the angle CZK is obtuse.

- S (upper left): vertex of quadrilateral on the circle
- P (upper right): vertex on the circle
- K (lower left): vertex on the circle
- C (lower right): vertex on the circle
- Z (center): center of the circumscribed circle

Second, it must be demonstrated that all the other points of the quadrilateral CKSP are farther from the center I than the point Z is. For let any other point θ be taken in the quadrilateral CKSP, and let the lines $I\theta$ and $Z\theta$ be joined. Then, since the angle $IZ\theta$ is right, by definition 3 of Book 11, [Margin: f — 19.pri. (Elements I.19)] the side opposite to it, $I\theta$, will be greater than the side IZ , which is opposite the smaller angle $I\theta Z$ (an acute one); and therefore the point θ is farther from the center I than the point Z is. By a similar argument we shall conclude that all the other points lie farther off.

Diagram. An oblique (three-dimensional) view of the quadrilateral, drawn as SPKC — S (upper left) and P (upper right) above, K (lower left) and C (lower right) below — with the apex I placed far to the left and joined to the figure by long lines. The point β lies within, near the top, with a small square marking the right angle there. The figure illustrates the perpendicular $I\beta$ dropped from I to the plane of the quadrilateral.

- I (far left): apex from which the perpendicular is drawn
- S (upper left), P (upper right): upper vertices
- K (lower left), C (lower right): lower vertices
- β (interior, near top): foot of the perpendicular; marked with a right angle

Third and last, it must be proved that the line ZC is greater than the line βP . To do this more suitably, it must first be demonstrated that the line PS is greater than the line QT. Let the upper part of the figure be described — namely, that which is contained by the semidiameters IC, IK, IO and the quadrants OC, OK, and so on. Then let the perpendiculars $Q\mu$ and $T\xi$ be dropped from Q and T to the plane of the circle ABCD, in which lies the triangle ICK; [Margin: g — 38.undecimi (Elements XI.38)] these will fall on the common sections IC and IK, [Margin: h — 6.undecimi (Elements XI.6)] and will be parallel to one another, as was said of the lines PX and SY. And if the line $\mu\xi$ be joined, QT and $\mu\xi$ will be parallel and equal, just as PS and XY were shown to be parallel and equal. [Margin: i — 2.sex. (Elements VI.2)] Now since $\mu\xi$ is parallel to CK — because the sides IC and IK are cut proportionally at μ and ξ , as we said of the line XY — [Margin: k — 30.pri. (Elements I.30)] $\mu\xi$ and XY will also be parallel. Hence, by the corollary of proposition 4 of Book 6, as IY is to YX, so is I ξ to $\xi\mu$. But IY is greater than I ξ ; [Margin: l — 14.quin. (Elements V.14)] therefore YX will also be greater than $\xi\mu$, and accordingly PS, which is equal to XY, will be greater than QT, which is equal to $\xi\mu$.

Diagram. A quarter-sphere (spherical sector) with its apex O at the upper left (the center of the sphere); a curved quadrant arc sweeps from the top down to K at the bottom, bounded on the left by a radius descending to L and along the bottom by a radius to G. Within, a dense network of chords joins the vertices of the inscribed polyhedron. Readable labels, working around and inside the figure: O (apex), R, V, T, Q, P, S, X, L, G, K. The figure is heavily foxed.

- O (apex, upper left): center of the sphere / vertex of the quadrant
- R (on the arc, upper): polyhedron vertex
- V, T (interior): polyhedron vertices

- Q (on the arc, right): polyhedron vertex
- P (right), S, X (lower interior): polyhedron vertices
- L (lower left corner), G (lower right): ends of the bounding radii
- K (bottom): vertex of the quadrant

This being demonstrated, let circles be described about the quadrilaterals CKSP and PSTQ from the centers Z and β , and from the centers let the lines ZC, ZK, ZS, ZP and βP , βS , βT [?], βQ go out. Then if ZC be not believed greater than βP , it will be either equal or less. Let it first be equal. Since, then, the sides ZK and ZC are assumed equal to the sides βS and βP , and the base KC is greater than the base PS, [Margin: m — 25.pri. (Elements I.25)] the angle KZC will be greater than the angle $S\beta P$; and by the same reasoning the angle SZP will be greater than the angle $T\beta Q$. But since the bases KS and CP are equal to the bases ST and PQ, [Margin: n — 8.pri. (Elements I.8)] the angles KZS and CZP will be equal to the angles $S\beta T$ [?] and $T\beta Q$ [?]. Therefore the four angles at Z will be greater than the four angles at β . Yet they are also equal, since both these and those are equal to four right angles, by corollary 2 of proposition 15 of Book 1 — which is absurd. Therefore the line ZC is not equal to the line βP .

Diagram. The left of a pair of circles. A circle circumscribing the quadrilateral SPKC — S (upper left), P (upper right), K (lower left), C (lower right) — with both diagonals drawn so that they cross at the center Z (marked with a monogram), forming an X within the quadrilateral.

- S, P, K, C: vertices of the inscribed quadrilateral
- Z (center): center of the circle, intersection of the diagonals

Diagram. The right of the pair of circles, for the case ZC less than βP . A circle with center β ; the upper vertices are T (left) and Q (right); within it an inner quadrilateral is formed by the cut-off points ω , ϕ , ρ , π [individual assignments uncertain], with diagonals crossing at β . A lower vertex P is marked; the lower-left vertex is illegible. [?]

- T (upper left), Q (upper right): vertices on the circle
- β (center): center of the circle
- ω , ϕ , ρ , π (interior): the points $\beta\pi$, $\beta\rho$, $\beta\omega$, $\beta\phi$ cut off equal to ZC, ZK, ZS, ZP [positions uncertain]
- P (lower right): vertex on the circle

Next, let ZC be less than βP . And let $\beta\pi$, $\beta\rho$, $\beta\omega$, $\beta\phi$ be cut off equal to ZC, ZK, ZS, ZP, and let the lines $\pi\rho$, $\rho\omega$, $\omega\phi$, $\phi\pi$ be joined, [Margin: o — 2.sex. (Elements VI.2)]

which will be parallel to the lines PS, ST, TQ, QP, because the lines cut off from the centers are cut proportionally; and accordingly, by the corollary of proposition 4 of Book 6, as βS is to SP, so will $\beta\rho$ be to $\rho\pi$. Since, then, βS is greater than $\beta\rho$, [Margin: p — 14.quin. (Elements V.14)] SP will also be greater than $\rho\pi$. And by the same reasoning ST, TQ, QP will be greater than the lines $\rho\omega$, $\omega\phi$, $\phi\pi$. And therefore, since PS is less than CK, and ST, PQ are equal to the lines KS, CP, and TQ is less than PS, the lines $\pi\rho$, $\rho\omega$, $\omega\phi$, $\phi\pi$ will be less than the lines CK, KS, SP, PC. Hence, since the lines $\beta\pi$, $\beta\rho$, $\beta\omega$, $\beta\phi$ are equal to the lines ZC, ZK, ZS, ZP, [Margin: q — 25.pri. (Elements I.25)] the angles at Z will be greater than the angles at β . Yet they are also equal, because both those and these are equal to four right angles, by corollary 2 of proposition 15 of Book 1 — which is absurd. Therefore the line ZC is not less than βP ; and it has been shown to be not equal either; therefore it is greater. Which was to be demonstrated.

THEOR. 18. PROPOS. 18.

[Margin: XV. (vulgate proposition number)]

Spheres are to one another in the triplicate ratio of their diameters.

Let there be two spheres ABC and DEF whose diameters are AC and DF. I say that the sphere ABC has to the sphere DEF the triplicate ratio of the diameter AC to the diameter DF. For if this be not granted, the sphere ABC will have — to some other sphere GHI smaller, or KLM larger, than DEF — the triplicate ratio of the diameter AC to the diameter DF. First let the sphere ABC have to the sphere GHI, smaller than the sphere DEF, the triplicate ratio of the diameter AC to the diameter DF, and let the sphere GHI be understood as concentric with the sphere DEF. [Margin: a — 17.duodecimi (Elements XII.17)] Let there be inscribed in the larger sphere DEF a polyhedron DNEOFPQR not touching the smaller sphere GHI, and let a polyhedron ASBTCVXY similar to this be inscribed in the sphere ABC. Since, then, the ratio of the sphere ABC to the sphere GHI is assumed to be the triplicate of the ratio of the diameter AC to the diameter DF, and since also, by the corollary of the preceding proposition, the ratio of the polyhedron ASBTCVXY to the polyhedron DNEOFPQR is the triplicate of the ratio of the diameter AC to the diameter DF, it will follow that as the sphere ABC is to the sphere GHI, so is the polyhedron ASBTCVXY to the polyhedron DNEOFPQR. Hence, since the sphere ABC is greater than the polyhedron ASBTCVXY, [Margin: b — 14.quin. (Elements V.14)] the sphere GHI will also be greater than the polyhedron DNEOFPQR — the part greater than the whole. Which is absurd. Therefore the sphere ABC will not have to a sphere GHI smaller than the sphere DEF the triplicate ratio of the diameter AC to the diameter DF.

Diagram. The figure for Proposition 18 (foxed; several labels uncertain). At the left, a circle for the sphere ABC with an inscribed eight-sided polyhedron ASBTCVXY: A (left) and C (right) lie on the horizontal diameter; B is at the top, S upper-left, T upper-right, Y lower-left, V lower-right, X at the bottom. At the upper right, a circle for the sphere DEF with an inscribed eight-sided polyhedron DNEOFPQR: D (left) and F (right) on the horizontal diameter; E at the top, N upper-left, O upper-right, R lower-left, P lower-right, and a bottom vertex Q (the stray "L" belongs to the shaded KLM solid, not this octagon); a smaller concentric circle GHI is drawn inside it (G left, H top, I right), representing the smaller sphere GHI. Below these, two shaded solid spheres: a smaller one (the sphere GHI) and a larger one labeled M (the sphere KLM), with K marked near its upper left.

- Sphere ABC: A, C (diameter ends), B (top), S, T (upper), Y, V (lower), X (bottom) — vertices of polyhedron ASBTCVXY
- Sphere DEF: D, F (diameter ends), E (top), N, O (upper), R, P (lower), Q (bottom) — vertices of polyhedron DNEOFPQR
- Inner circle GHI: G (left), H (top), I (right) — the concentric smaller sphere
- Shaded solids: small sphere (GHI); large sphere M (KLM), with K marked

Next, let the sphere ABC have to the sphere KLM, larger than the sphere DEF, the triplicate ratio of the diameter AC to the diameter DF. Then, since by the corollary of the preceding proposition the polyhedron ASBTCVXY also has to the polyhedron DNEOFPQR the triplicate ratio of the diameter AC to the diameter DF, it will follow that as the sphere ABC is to the sphere KLM, so is the polyhedron ASBTCVXY to the polyhedron DNEOFPQR; and, inversely, as the sphere KLM is to the sphere ABC, so is the polyhedron DNEOFPQR to the polyhedron ASBTCVXY. But, by the said corollary of the preceding proposition, the polyhedron DNEOFPQR is to the polyhedron ASBTCVXY in the triplicate ratio of the diameter DF to the diameter AC. Therefore the sphere KLM will also be to the sphere ABC in the triplicate ratio of the diameter DF to the diameter AC. Let it be posited that, as the sphere KLM is to the sphere ABC, so is the sphere DEF to another sphere $Z\alpha\beta$. Then the sphere DEF will also have to the sphere $Z\alpha\beta$ the triplicate ratio of the diameter DF to the diameter AC. And since the sphere KLM is posited greater than the sphere DEF, the sphere ABC will also be greater than the sphere $Z\alpha\beta$. Wherefore the sphere DEF has to the sphere $Z\alpha\beta$ — which is smaller than the sphere ABC — the triplicate ratio of the diameter DF to the diameter AC. Which is absurd; for it has been shown that a sphere cannot have to another sphere smaller than it the triplicate ratio of the diameters. Therefore the sphere ABC will not have to the sphere KLM, larger than the sphere DEF, the triplicate ratio of the

diameter AC to the diameter DF. But neither does it have it to a smaller one, as has been demonstrated. Therefore it will have to the sphere DEF the triplicate ratio of the diameter AC to the diameter DF. And so spheres are to one another in the triplicate ratio of their diameters. Which was to be demonstrated.

Diagram. The figure for Proposition 18 repeated (identical to fig-p545-5; foxed). At the left, the circle for the sphere ABC with inscribed polyhedron ASBTCVXY: A (left) and C (right) on the horizontal diameter, B (top), S upper-left, T upper-right, Y lower-left, V lower-right, X (bottom). At the upper right, the circle for the sphere DEF with inscribed polyhedron DNEOFPQR (D and F on the diameter; E top; N, O upper; R, P lower; a bottom vertex Q, the stray "L" belonging to the shaded KLM solid) and the concentric inner circle GHI (G left, H top, I right). Below, two shaded solid spheres: a smaller one (GHI) and a larger one labeled M (KLM), with K marked.

- Sphere ABC: A, C, B, S, T, Y, V, X — vertices of polyhedron ASBTCVXY
- Sphere DEF: D, F, E, N, O, R, P, Q — vertices of polyhedron DNEOFPQR
- Inner circle GHI: G, H, I — the concentric smaller sphere
- Shaded solids: small sphere (GHI); large sphere M (KLM), with K marked

COROLLARIUM.

Hence it follows that a sphere is to a sphere as a polyhedron described in the one is to a similar polyhedron described in the other. For both the sphere to the sphere and the polyhedron to the polyhedron have the triplicate ratio of the diameters, as has been demonstrated.

EUCLID'S THIRTEENTH ELEMENT

And the Third [Book] of Solids

THEOR. 1. PROPOS. 1.

If a straight line is cut in extreme and mean ratio, then the greater segment, taking to itself half of the whole, is capable of five times the square described on half of the whole.

Let the straight line AB be cut in extreme and mean ratio at C, so that AC is the greater segment. Let BA be produced to D, so that AD is half of the whole AB. I say that the square on the line CD is five times the square on the line AD.

For let the square CE be described on CD. In it draw the diameter DF, and draw AG parallel to DE, cutting the diameter at the point H; and through H draw Ik parallel to CD. Then produce GA, complete the square AM, and produce FC to N. By the corollary of Proposition 4 of Book 2 [II.4], AI and kG will be the squares on the lines AD and AC.

[Margin: a — VI, definition 3] Now since, as AB is to AC, so is AC to CB, [Margin: b — VI.17] the rectangle CM contained by AB, CB will be equal to kG, the square on the line AC. Next, since AB is set equal to twice AD, and AL is set equal to AB, and AH equal to AD, then AL will also be double AH. [Margin: c — VI.1] And as AL is to AH, so is the rectangle AN to the rectangle Ak. Therefore AN is double Ak.

[Margin: d — I.43] But since Ak is equal to IG, AN will be equal to the two Ak and IG together. Therefore, adding the equal quantities CM and kG, the square AM will be equal to the gnomon OPQ. And since the square AM is four times the square AI — by the scholium of Proposition 4 of Book 2, because the line AB is set as double the line AD — the gnomon OPQ will likewise be four times the same square AI. Consequently, if to the gnomon OPQ the square AI itself is added, the square CE is made five times the square AI.

Diagram. A geometric construction for Proposition 1: an upper square (the square CE on CD) containing an inscribed circle and its diagonal, sitting above a lower rectangle (the square AM region on AB). Labelled points read from the figure:

- E (top-left corner of upper square)
- G (top edge, midpoint)
- F (top-right corner of upper square)
- P (upper part of the inscribed circle, on the diagonal)
- I (left edge, at the level of the horizontal Ik)
- O (left-of-centre, on line Ik)
- H (centre, intersection of diameter and Ik)
- K (right edge, on line Ik)
- D (left end of the middle horizontal line)
- A (just below D, left end of AB)
- Q (centre-low)
- C (centre-right, on line AB)

- B (right end of line AB)
- L (bottom-left corner of lower rectangle)
- N (bottom edge, midpoint)
- M (bottom-right corner of lower rectangle)

ALITER [Another way]. By the scholium of Proposition 4 of Book 2, the square on the line AB is four times the square on the line AD, since AB is set as double AD. [Margin: e — II.2] Now the square on the line AB is equal to the rectangles contained by AB, BC and by AB, AC together; and again, the rectangle contained by AB, AC is equal to twice the rectangle contained by AD, AC. [Margin: f — VI.1] (For just as AB is double AD, so too the rectangle under AB, AC will be double the rectangle under AD, AC, since both rectangles have the same height AC; and therefore twice the rectangle under AD, AC will be equal to the rectangle under AB, AC.) [Margin: g — VI.17] But the rectangle under AB, BC is equal to the square on the line AC, since, as AB is to AC, so is AC to CB. Therefore the square on the line AC, together with twice the rectangle under AD, AC, will likewise be four times the square on the line AD. And so the squares on the lines AC and AD, together with twice the rectangle under AD, AC, will be five times the square on the same line AD. [Margin: h — II.4] Hence, since the square on the line CD is equal to the squares on the lines AC and AD together with twice the rectangle under AD, AC, the square on the line CD will also be five times the square on the line AD. Therefore, if a straight line is cut in extreme and mean ratio, and so on. Which was to be demonstrated.

THEOR. 2. PROPOS. 2.

If a straight line is capable of five times the square on a segment of itself, then, when twice the said segment is cut in extreme and mean ratio, the greater segment is the remaining part of the original straight line.

Let the straight line AB be divided at C, and let it be capable of five times [the square on] the segment AC; and let CD be taken as double AC,

which — as we shall show below — will be greater than the remaining segment BC. I say that if CD is cut in extreme and mean ratio, its greater segment is CB, the remaining part of the original line.

For let the square BF be described on AB. In it draw the diameter AE, and from C draw CG parallel to AF, cutting the diameter at the point H; and through H let IK be drawn parallel to AB. Then produce GC and complete the square CM, producing EB to N. By the corollary of Proposition 4 of Book 2 [II.4], CI and KG will be the squares on the lines AC and CB. Now since the square BF is set as five

times the square CI, then, if the square CI is taken away, there remains the gnomon OPQ, which is four times the same square CI. But the square CM is also four times the square CI, by the scholium of Proposition 4 of Book 2, because the line CD is double AC. Therefore the gnomon OPQ will be equal to the square CM. Again, since CD is set as double AB, and LC is equal to CD, and CH equal to AC, then LC will also be double CH. [Margin: a — VI.1] Since therefore, as LC is to CH, so is the rectangle LB to the rectangle CK, that [rectangle LB] will likewise be double this [rectangle CK]. [Margin: b — I.43] But CK is equal to HF. Therefore the remaining square KG is also equal to the remaining rectangle BM. Now since the rectangle BM, contained under CD, BD, is equal to KG, the square on the line CB, [Margin: c — VI.17] it will be that, as CD is to CB, so is CB to BD. For which reason, by the definition, the line CD is cut at B in extreme and mean ratio, and CB is the greater segment.

Diagram. A geometric construction for Proposition 2, similar to the previous figure but reoriented: an upper square (BF on AB) with an inscribed circle and diagonal AE, above a lower rectangle. Labelled points read from the figure:

- F (top-left corner of upper square)
- G (top edge, midpoint)
- E (top-right corner of upper square)
- P (upper part of the inscribed circle, on the diagonal)
- J/I (left edge, at the level of line IK) [reads as "J"/"I"; the printed point-letter for line IK]
- O (left-of-centre, on line IK)
- H (centre)
- K (right edge, on line IK)
- A (left, at foot of upper square)
- Q (centre-low)
- C (just below Q, foot of the diagonal region)
- B (right, foot of upper square)
- L (bottom-left corner of lower rectangle)
- N (bottom edge, midpoint)
- M (bottom-right corner of lower rectangle)

ALITER [Another way]. Since the square on the line AB is set as five times [the square on the line AC], and the square on the line AB is equal to the squares on the lines CB, AC together with twice the rectangle under AC, CB, then the squares on the lines CB, AC, together with twice the rectangle under AC, CB, will be five

times the square on the line AC. [Margin: d — II.4] Therefore, if the square on the line AC is subtracted, there remains the square on the line CB together with the rectangle under AC, CB taken twice, [equal to] four times the same square on the line AC; and the square on the line CD is [set as] four times the same square on the line AC, [Margin: e — VI.1] and so the square on the line CB together with twice the rectangle under AC, CB is equal to the square on the line CD. (For, just as the line CD is double the line AC, so too twice the rectangle under CD, CB will be double the rectangle under AC, CB, since both rectangles have the same height CB; and therefore twice the rectangle under AC, CB will be equal to the rectangle under CD, CB.) Therefore the [rectangle] under CD, CB will be equal to the square on the line CD. [Margin: f — II.2] But the square on the line CD [together with the rectangle] under CD, BD [is equal to the squares under CD, CB and under CD, BD]; therefore the square on the line CB and the rectangle under CD, CB [together] will be equal to the rectangle under CD, BD. [Margin: g — VI.17] And so, when the common rectangle under CD, CB is taken away, there remains the square on the line CB equal to the rectangle under CD, BD; and therefore, as CD is to CB, so will CB be to DB. For which reason, by the definition, the line CD is cut at B in extreme and mean ratio, and CB is the greater segment. Therefore, if a straight line is capable of five times the square on a segment of itself, and so on. Which was to be demonstrated.

Diagram. A single divided straight line marking the points, in order: A, C, B, D (with the segments AC, CB, BD tick-marked).

LEMMA.

That the line CD is of necessity greater than CB we shall show from the hypothesis, as follows. Since the square on the line CD is four times [the square on the line AC], by the scholium of Proposition 4 of Book 2, then, adding the square on the line AC, the two squares on the lines CD, AC will be five times the same square on the line AC. But the square on the line AD is greater than the squares on the lines AC, CD together with twice the rectangle under AC, CD. Therefore the square on the line AD is also greater than five times the square on the line AC; and consequently greater than the square on the line AB, which is set as five times the same square on the line AC. Therefore the line AD will be greater than the line AB; and so, when the common part AC is taken away, the remaining CD will be greater than the remaining CB. Which was proposed.

THEOR. 3. PROPOS. 3.

If a straight line is cut in extreme and mean ratio, then the lesser segment, taking to itself half of the greater segment, is capable of five times the square described on half of the greater segment.

Let the straight line AB be cut in extreme and mean ratio at C, so that its greater segment is AC, and let AC be bisected at D. I say that the square on the line BD is four times the square on the line CD.

For let the square AE be described on AB, in which is the diameter BF. Then from C, D draw CG, DH parallel to AF, BE, cutting the diameter at the points I, K; through which draw LM, NO parallel to AB, EF, which cut the lines CG, DH at P, Q. By the corollary of Proposition 4 of Book 2 [II.4], LG, PQ, DO will be the squares on the lines AC, CD, BD. Now since the line AC is double the line CD, then, by the scholium of the same proposition, the square LG will be four times the square PQ. And the rectangle CE is equal to the square LG. (For since,

Diagram. A square (AE on AB) subdivided by two vertical and two horizontal lines into a grid, with the diagonal FB drawn and an inscribed arc. Labelled points read from the figure:

- F (top-left corner)
- H (top edge, left of centre)
- G (top edge, right of centre)
- E (top-right corner)
- N (left edge)
- K (interior, upper-left)
- Q (interior, upper-right)
- O (right edge)
- L (left edge, lower)
- D (interior, left of centre — repeated in the bottom row)
- R (interior, centre-left, on the arc)
- T (interior centre, small label)
- I (interior, centre-right)
- M (right edge, lower)
- A (bottom-left corner)
- D (bottom edge, left of centre)
- C (bottom edge, centre)
- B (bottom-right corner)

- S (bottom edge region, on the arc, centre)

[Continued on p. 549:] as AB is to AC, so is AC to CB, [Margin: a — VI.17] the rectangle under AB, CB — namely CE — will be equal to the square on the line AC, that is, to LG.) Therefore CE also will be four times the square PQ. And since the lines AD, CD are equal, their sides HK, IQ will be equal, [Margin: b — I.34] and the opposite [rectangles] will be equal. [Margin: c — I.36] Therefore the rectangles IO, QE will be equal. [Margin: d — I.43] And QE will be equal to the same ID; and consequently, adding the common rectangle CO, [the whole] CE will be equal. Since therefore CE has been shown to be four times the square PQ, [the gnomon is] four times the same square PQ; and consequently, adding the square PQ, [the square DO] is five times the square PQ, that is, [five times the square] on the line CD.

ALITER [Another way]. Since AC has been bisected at D, and CB added to it, [Margin: e — II.6] the [rectangle under AB, BC together with] the square on the line CD is equal to the square on the line BD. But the rectangle under AB, BC is four times the square on the line CD; ([Margin: f — VI.17 [?]] for since, as AB is to AC, so is AC to CB, the rectangle under AB, BC is equal to the square on the line AC; and since, by the scholium of Proposition 4 of Book 2, the square on the line AC is four times the square on the line CD, the rectangle under AB, BC will also be four times the same square on the line CD.) And therefore the rectangle under AB, BC, together with the square on the line CD, will be five times the square on the line CD; that is, the square on the line BD is five times the square on the line CD. Therefore, if a straight line is cut in extreme and mean ratio, and the lesser segment takes to itself half of the greater segment, it is capable of five times the square described on half of the greater segment. Which was to be shown.

Diagram. A single divided straight line marking the points, in order: A, D, C, B (with segments tick-marked).

SCHOLIUM.

The converse of this theorem we shall also demonstrate, with Campanus [Campanus of Novara], in this manner:

If a straight line is cut unequally, and the lesser segment, taking to itself half of the greater segment, is capable of five times the square described on half of the greater segment, then that straight line is cut in extreme and mean ratio.

Let the line AC be divided unequally at C, whose greater segment AC is bisected at D; and let the square on the line BD be five times the square on the line CD. I say that the line AB is divided at C in extreme [and mean ratio]. For, the figure of the previous proposition being repeated, the square LG will be four times the square PQ, [that is, four times the square] on the line CD, by the scholium of Proposition 4 of Book 2. And the gnomon RST is four times the same square PQ. (For since the square DO, on the line BD, is set as five times the square PQ, on the line CD, then, when the square PQ is taken away, there remains the gnomon RST, four times the same square [PQ]; and this will be equal to the square LG. But the rectangle CE is equal to the gnomon RST, as was shown above; [Margin: g — VI.17] and so the rectangle CE, contained under AB, BC, will be equal to the same [square] on the line AC.) And consequently, as AB is to AC, so is AC to CB. For which reason, by the definition, the line AB will be cut at C in extreme and mean ratio. Which was proposed.

ALITER [Another way]. Since AC has been bisected at D, and GB added to it, [Margin: h — II.6] the rectangle under AB, BC, together with the square on the line CD, is equal to the square on the line BD. And therefore, since the square described on the line BD is five times the square described on the line CD, the rectangle under the lines AB, BC, described together with the square on the line CD, will be five times the same square on the line CD. So, when the square on the line CD is taken away, the rectangle under AB, BC will be four times the square [on the line CD]. But four times the square on the line CD is equal to the square on the line AC; therefore the rectangle under AB, BC is equal to the square on the line AC. [Margin: i — VI.17] For which reason, as AB is to AC, so is AC to CB; and consequently the line AB is cut at C in extreme and mean ratio, by the definition.

THEOR. 4. PROPOS. 4.

If a straight line is cut in extreme and mean ratio, then the squares on the whole and on the lesser segment together are triple the square described on the greater segment.

Let the straight line AB be cut in extreme and mean ratio at C, so that the greater segment is AC and the lesser CB. I say that the squares on the lines AB, BC together are triple the square on the line AC.

For let the square AD be described on AB, in which is drawn the diameter BE; and from C draw CF parallel to BD, cutting the diameter at the point G; through which draw HI parallel to AB. By the corollary of Proposition 4 of Book 2 [II.4], CH, IF will be the squares on the lines BC, AC. Now since, as AB is to AC, so is AC to CB,

[Margin: a — VI.17] the rectangle under AB, BC — namely AH — will be equal to IF, the square on the line AC. Since therefore AH is equal to CD, the gnomon KLM, together with the square CH, will be double the square IF; and consequently, adding the square IF, the square AD, on the line AB, together with the square CH, on the line BC, will be triple the same square IF, on the line AC.

Diagram. A square (AD on AB) with the diagonal EB, a subdividing parallel CF and horizontal HI, and an inscribed quarter-arc. Labelled points read from the figure:

- E (top-left corner)
- F (top edge, centre)
- D (top-right corner)
- K (interior, upper, on the arc)
- I (left edge, at the level of line HI) [printed as a single point-letter on the left]
- M (interior, left of centre, on line HI)
- G (interior centre, intersection point)
- H (right edge, at the level of line HI) [the point-letter reads as a double stroke "II"; taken as H per the demonstration's "HI"]
- L (interior, lower-right, on the diagonal near B)
- A (bottom-left corner)
- C (bottom edge, centre)
- B (bottom-right corner)

ALITER [Another way]. Since, as AB is to AC, so is AC to CB, [Margin: b — VI.17] the rectangle under AB, BC will be equal to the square on the line AC; and so twice the rectangle under AB, BC, together with the square on the line AC, is triple the square on the line AC. [Margin: c — II.7] But the squares on the lines AB, BC together are equal to the square on the line AC together with twice the rectangle under AB, BC. Therefore the squares on the lines AB, BC together are triple the square on the line AC. Consequently, if a straight line is cut in extreme and mean ratio, then the squares on the whole and on the lesser segment together are triple the square described on the greater segment. Which was to be demonstrated.

SCHOLIUM.

The converse of this too is true, namely:

(Continuation of the Scholium to Proposition 4 — the converse.)

If a straight line is cut unequally, and the square on the whole together with the square on the lesser segment is three times the square described on the greater segment, then that line will be cut in extreme and mean ratio.

Let the line AB be cut unequally at C, so that the square on the whole AB and the square on the lesser segment BC, taken together, are three times the square on the greater segment AC. I say that AB is cut in extreme and mean ratio. For, with the figure constructed as before: since the squares AD and CH together are three times the square IF, then, once the square IF is subtracted, the gnomon KLM together with the square CH will be twice that same square IF. But the gnomon KLM together with the square CH is equal to the two rectangles AH and CD. Therefore the rectangles AH and CD together are twice the square IF; and since AH and CD are equal, AH will be equal to IF. Consequently, since the rectangle AH — that is, the rectangle contained by AB and BC — is equal to the square IF on AC, [Margin: d — *Elements* VI.17] as AB is to AC, so AC will be to CB; and therefore AB is divided at C in extreme and mean ratio.

ANOTHER WAY. Since the squares on the lines AB and BC are three times the square on AC, [Margin: e — *Elements* II.7] and since the squares on AB and BC are equal to the square on AC together with twice the rectangle contained by AB and BC, then the square on AC together with twice the rectangle contained by AB and BC will be three times the square on AC. Therefore, subtracting the square on AC, there remains twice the rectangle contained by AB and BC, equal to twice the square on AC. And so the rectangle contained by AB and BC, taken once, is equal to the square on AC. [Margin: f — *Elements* VI.17] Hence, as before, as AB is to AC, so AC will be to CB; and therefore AB is cut at C in extreme and mean ratio.

From Francesco Maurolico [Maurolico] we shall also demonstrate the theorem that follows.

If a straight line is cut in extreme and mean ratio, then the square on the whole line together with the lesser segment is five times the square described on the greater segment. And if a straight line is cut unequally, and the square on the whole line together with the lesser segment can be five times the square described on the greater segment, then that line is cut in extreme and mean ratio.

Let the line AB first be cut at C in extreme and mean ratio, and let the line BD, equal to the lesser segment BC, be added to it. I say that the square on AD is five times the square on AC, the greater segment. [Margin: g — *Elements* II.8] For since

the square on AD is equal to four times the rectangle contained by AB and BC, together with the square on AC, [Margin: h — *Elements* VI.17] and since the rectangle contained by AB and BC is equal to the square on AC (because AB, AC, CB are in continued proportion), the rectangle contained by AB and BC taken four times will be four times the square on AC; and so four times the rectangle contained by AB and BC, together with the square on AC, is five times the square on AC. Therefore the square on AD — which has been shown equal to four times the rectangle contained by AB and BC together with the square on AC — will likewise be five times that same square on AC. This is what was proposed.

Next, let the line AB be cut unequally at C, and let the line BD, equal to the lesser segment BC, be added to it, and let the square on AD be five times the square on AC, the greater segment. I say that AB is cut at C in extreme and mean ratio. [Margin: i — *Elements* II.8] For since the square on AD is equal to four times the rectangle contained by AB and BC, together with the square on AC, then four times the rectangle contained by AB and BC together with the square on AC will also be five times the square on AC; and consequently four times the rectangle contained by AB and BC will be four times the square on AC — that is, the rectangle contained by AB and BC is equal to the square on AC. [Margin: k — *Elements* VI.17] Therefore, as AB is to AC, so AC will be to CB; and hence AB is cut at C in extreme and mean ratio. This is what was proposed.

Diagram. A single straight line divided at one interior point, used for the "another way" argument of the Proposition 4 scholium.

- A (left end): endpoint of the whole line
- C (interior): point of division
- B (right end): endpoint, marking the lesser segment CB

Diagram. A straight line AB cut at C and extended beyond B to D, for the Maurolico theorem (BD added equal to the lesser segment BC).

- A (left end): endpoint of the whole line
- C (interior): point of division into greater segment AC and lesser BC
- B (right of C): endpoint of the original line AB
- D (right end): endpoint of the added segment BD (equal to BC)

THEOR. 5. PROPOS. 5.

[Margin: iv.]

If a straight line is cut in extreme and mean ratio, and there is added to it a line equal to the greater segment: then the whole line is cut in extreme and mean ratio, and the greater segment is the original straight line.

Let the line AB be cut at C in extreme and mean ratio, let the greater segment be AC, and let AD, equal to the greater segment AC, be added to it in a straight line. I say that the line BD is cut at A in extreme and mean ratio, and that the greater segment is AB. For let the square BF be described on AB. In it, when the diagonal AE has been drawn, let CG be drawn from C parallel to BE, cutting the diagonal at the point H; through H let IK be drawn parallel to BD; and from D let DL be drawn parallel to AF, meeting IK, produced, at L. Then, by the corollary of Proposition 4 of Book 2, CK and IG will be the squares on the lines AC and BC. Now since, as AB is to AC, so AC is to CB, [Margin: a — *Elements* VI.17] the rectangle IF, contained by AB and BC, will be equal to the square CK on the line AC. [Margin: b — *Elements* I.36] But CK is equal to AL. Therefore IF will be equal to AL; and, adding the common part BK, the rectangle BL, contained by BD and DA, will be equal to the square BF on the line AB. [Margin: c — *Elements* VI.17] Hence, as BD is to AB, so AB will be to DA. Therefore BD is cut at A in extreme and mean ratio, and the greater segment is AB.

ANOTHER WAY. Since, as AB is to AC — that is, to AD — so AC is to CB, then by conversion, as DA is to AB, so BC will be to CA; and by composition, as DB is to AB, so AB is to CA, that is, to AD. Therefore BD is cut at A in extreme and mean ratio. And so, if a straight line is cut in extreme and mean ratio, and there is added to it a line equal to the greater segment, the whole line, and so on. Which was to be demonstrated.

Diagram. The square construction for Proposition 5, erected on AB with its diagonal AE and the auxiliary parallels CG, IK, DL. The baseline (extended beyond A to D) carries D, A, C, B; the middle horizontal carries L, K, H, I; the top edge carries F, G, E. A diagonal runs from A up to E.

- F (top-left): upper-left vertex of the square on AB
- G (top-middle, above C): point on the top edge where CG meets it
- E (top-right): upper-right vertex of the square (end of the diagonal AE)
- L (middle-left): where DL meets the produced line IK
- K (middle, on the left side): point on side AF
- H (middle-centre): intersection of the diagonal AE with CG

Diagram. The straight line for the "another way" of Proposition 5: line DB cut at A, with A cut again at C.

- D (left end): endpoint of the whole line DB
- A (interior): point where DB is cut in extreme and mean ratio
- C (interior, right of A): point dividing AB
- B (right end): endpoint

SCHOLIUM.

In the same way we shall demonstrate this too, along with Campanus [Campanus].

If a straight line is cut in extreme and mean ratio, and the lesser segment is subtracted from the greater, then the greater segment is itself cut in extreme and mean ratio, and its greater segment is that line which was the lesser segment of the original line.

Let the line BD be cut at A in extreme and mean ratio, its greater segment being AB and its lesser segment AD; and from the greater segment AB let the line AC, equal to the lesser segment AD, be subtracted. I say that the greater segment AB is divided at C in extreme and mean ratio, and that its greater segment is the line AC, which is equal to the lesser segment AD. For, with the construction of the earlier figure carried out: since, as BD is to AB, so AB is to AD, [Margin: d — *Elements* VI.17] the rectangle BL, contained by BD and AD, will be equal to the square BF on the line AB; and, removing the common part BK, AL will be equal to IF. [Margin: e — *Elements* I.36] But AL is equal to CK. Therefore IF, contained by AB and CB, is equal to the square CK on the line AC. [Margin: f — *Elements* VI.17] Hence, as AB is to AC, so AC is to CB. Therefore AB is cut at C in extreme and mean ratio, its greater segment being AC and its lesser segment the line CB. This is what was proposed.

ANOTHER WAY. Since, as the whole BD is to the whole AB, so is AB — that is, AC, subtracted from BD — to AD, that is, to AC, subtracted from AB; [Margin: g — *Elements* V.19] then also, as AD, the remainder of BD — that is, AC — is to CB, the remainder of AB, so is the whole DB to the whole AB, that is, as AB is to AC. Therefore AB is divided at C in extreme and mean ratio. This is what was proposed.

Again, we shall demonstrate the following too.

If a line is cut in extreme and mean ratio, and from its half is taken the half of the greater segment: then the half of the whole is likewise cut in extreme and mean ratio, and its greater segment is half of the greater segment of the whole line.

For let AB be divided at C in extreme and mean ratio, let DE be the half of the whole, and DF the half of the greater segment AC. I say that DE is cut at F in extreme and mean ratio, and that its greater segment is DF. For since, as the whole AB is to the whole DE, so is the subtracted AC to the subtracted DF — the ratio being double in each case — [Margin: h — *Elements* V.19] the remainder CB will also be to the remainder FE as the whole is to the whole; and hence CB will be double FE. [Margin: i — *Elements* V.15] Now since, as AB is to AC, so is DE, the half of AB, to DF, the half of AC — and since, by the definition of a line cut in extreme and mean ratio, AB is to AC as AC is to CB — then also DE will be to DF as DF is to FE. And so, by the same definition, DE will be cut at F in extreme and mean ratio. This is what was proposed.

Diagram. Two parallel straight lines, one above the other: the upper line carries A, C, B (the whole AB cut at C); the shorter lower line carries D, F, E (its half DE cut at F).

- A (upper line, left): endpoint of the whole line
- C (upper line, middle): point of section in extreme and mean ratio
- B (upper line, right): endpoint
- D (lower line, left): endpoint of the half-line DE
- F (lower line, middle): point of section of DE
- E (lower line, right): endpoint of the half-line

THEOR. 6. PROPOS. 6.

[Margin: vj.]

If a rational straight line is cut in extreme and mean ratio, each of the segments is an irrational line, of the kind called an apotome.

Let the rational line AB be cut at C in extreme and mean ratio. I say that each segment, AC and CB, is an irrational line, of the kind called an apotome. For let AD, equal to half the whole AB, be added to the greater segment AC. [Margin: a — *Elements* XIII.1] Since, then, the square on the line CD is five times the square on the line AD, the square on CD will have to the square on AD a ratio which a

number has to a number. [Margin: b — *Elements* X.6] Therefore the squares on the lines CD and AD are commensurable; and consequently the lines CD and AD themselves are also commensurable, at least in square. But AD is rational, since it is half the rational line AB. Therefore CD too will be rational. Now since the squares on the lines CD and AD do not have to one another a ratio which a square number has to a square number (as is clear from the corollary of Proposition 24 of Book 8 — for they have the ratio of 5 to 1, or of 25 to 5), [Margin: c — *Elements* X.9] the lines CD and AD will be incommensurable in length; and consequently they are rational lines commensurable in square only. Therefore, if from CD, which is rational, there is subtracted AD, which is rational and commensurable in square only, [Margin: d — *Elements* X.74] the remainder AC will be irrational, of the kind called an apotome.

Again, let the rectangle AE, contained by AB and CB, be applied to AB. [Margin: e — *Elements* VI.17] Then the rectangle AE will be equal to the square on the line AC. For this reason the square on the apotome AC — namely the rectangle AE, applied along the rational line AB — [Margin: f — *Elements* X.98] makes its other side BE, that is, the line CB equal to it, a first apotome. Therefore, if a rational straight line is cut in extreme and mean ratio, and so on. Which was to be demonstrated.

Diagram. The figure for Proposition 6: a horizontal line carrying D, A, C, B (with AD added to AC), and a rectangle erected on AB whose upper-right corner is E, with verticals dropped at A and at C (the applied rectangle AE).

- D (baseline, left): end of the added segment AD
- A (baseline): endpoint of the original line / point of section
- C (baseline): point of section in extreme and mean ratio
- B (baseline, right): endpoint of the line AB
- E (upper-right): upper vertex of the rectangle applied along AB

(Continuation of the Scholium to Proposition 6.)

But we shall also show this theorem along with Campanus [Campanus].

If a straight line is cut in extreme and mean ratio, and the greater segment is a rational line, then the lesser segment is an apotome.

Let the line AB be divided at C in extreme and mean ratio, and let the greater segment AC be a rational line. I say that the lesser segment CB is an apotome. For let AC be bisected at D. Then CD, half of the rational line AC, will be rational, since it is commensurable with AC. [Margin: g — *Elements* XIII.3] Now since the square

on the line BD is five times the square on the line CD, the squares on the lines BD and CD will have to one another a ratio which a number has to a number; [Margin: h — *Elements* X.6] and consequently they will be commensurable. Therefore the lines BD and CD themselves will also be commensurable, at least in square. Since, then, CD is rational, BD too will be rational. But since the squares on the lines BD and CD do not have to one another a ratio which a square number has to a square number (as is clear from the corollary of Proposition 24 of Book 8 — for they have the ratio of 5 to 1, or of 25 to 5), the lines BD and CD will be incommensurable in length. And hence, if from the rational line BD there is subtracted CD, which is rational and commensurable in square only, [Margin: i — *Elements* X.74] the remainder CB will be irrational, of the kind called an apotome.

Diagram. A single straight line for the continuation of the Proposition 6 scholium, carrying A, D, C, B.

- D (interior): midpoint of AC
- C (interior): point of section of AB
- B (right end): endpoint (lesser segment CB)

THEOR. 7. PROPOS. 7.

[Margin: vij.]

If three angles of an equilateral pentagon are equal — whether they are consecutive or not consecutive — then the pentagon is equiangular.

First case. Let three angles of the equilateral pentagon ABCDE, which are first taken as consecutive, be equal: A, B, C. I say that the pentagon is equiangular. For let the lines BE, AC, BD be drawn subtending the said equal angles; and from the point F, where the lines BE and AC intersect, let ED be drawn. Since, then, the sides AB, AE of triangle ABE are equal to the sides CB, CD of triangle CBD, and the angles contained by them are also equal, by hypothesis, [Margin: a — *Elements* I.4] the bases BE, BD and the angles AEB, CDB will be equal. [Margin: b — *Elements* I.5] But the angles BED, BDE are also equal, since the sides BE, BD have been shown equal. Therefore the whole angles AED, CDE will be equal. Again, since the sides AB, AE of triangle ABE are equal to the sides BA, BC of triangle BAC, and the angles contained by them are also equal, by hypothesis, [Margin: c — *Elements* I.4] the base BE will be equal to the base AC, and the angles ABE, AEB equal to the angles BAC, BCA. Since, then, the angles ABE, BAC of triangle ABF are equal, [Margin: d — *Elements* I.6] the sides BF, AF will also be equal; and

consequently, if these are subtracted from the equal lines BE, AC, the remaining lines FE, FC will be equal. And so, since the sides FE, ED of triangle FED are equal to the sides FC, CD of triangle FCD, and the base FD is common, [Margin: e — *Elements* I.8] the angles contained by the said sides, FED and FCD, will also be equal. But the angles AEB, BCA have also been shown equal. Therefore the whole angles AED, BCD are equal. And hence, since the angle CDE has been shown equal to the angle AED, and the angles ABC, BAE are supposed equal to the angle BCD, all the angles of the pentagon will be equal, and so the pentagon will be equiangular.

Second case. Let three non-consecutive angles be equal: A, C, D. Since, then, the sides AB, AE of triangle ABE are equal to the sides CB, CD of triangle CBD, and the angles contained by them are also equal, by hypothesis, [Margin: f — *Elements* I.4] the bases BE, BD and the angles AEB, CDB will be equal; [Margin: g — *Elements* I.5] but the angles BED, BDE are also equal, since the sides BE, BD have been shown equal. Therefore the whole angles AED, CDE will be equal. And so, since the angles BAE, CDE are supposed equal, there will be three consecutive equal angles, A, E, D; and hence, as has already been demonstrated, the pentagon will be equiangular. Therefore, if three angles of an equilateral pentagon are equal, and so on. Which was to be demonstrated.

Diagram. The equilateral pentagon ABCDE with the diagonals BE, AC, BD drawn and ED joined, meeting the interior point F.

THEOR. 8. PROPOS. 8.

[Margin: viij.]

If two straight lines subtend two consecutive angles of an equilateral and equiangular pentagon, then they cut one another in extreme and mean ratio, and their greater segments are equal to the side of the pentagon.

In the equilateral and equiangular pentagon ABCDE, let the lines DB, CE subtend the two consecutive angles C and D, cutting one another at F. I say that they are

cut in extreme and mean ratio, and that their greater segments FB, FE are equal to any side of the pentagon. [Margin: a — *Elements* IV.14] For let a circle be described about the pentagon; [Margin: b — *Elements* III.28] then the five arcs AB, BC, CD, DE, EA will be equal. Now since the sides CD, CB of triangle CDB are equal to the sides DC, DE of triangle DCE, and the angles contained by them are also equal, by hypothesis, [Margin: c — *Elements* I.4] the bases DB, CE and the angles CDB, DCE will be equal. And hence, in triangle CDF, the two angles FCD, FDC are equal; [Margin: d — *Elements* I.32] and the external angle BFC is equal to them together, so that the angle BFC is double the angle DCE. [Margin: e — *Elements* VI.33] But the angle BCE is also double that same angle DCE, since the arc BAE is likewise double the arc DE. Therefore the angles BFC, BCF are equal; [Margin: f — *Elements* I.6] and so the line BF is equal to the side BC of the pentagon. [Margin: g — *Elements* III.27] Now since the angles DBC, ECD, standing on equal arcs, are equal, the two angles DBC, CDB of triangle BCD will be equal to the two angles DCF, FDC of triangle CFD. [Margin: h — *Elements* I.32] And hence the triangles BCD, CFD will be equiangular. [Margin: i — *Elements* VI.4] Therefore, as BD is to DC, so DC — that is, its equal BF — is to FD; and consequently BD is cut at F in extreme and mean ratio, and its greater segment BF is equal to the side of the pentagon, as has been shown. By a like argument we shall show that the line CE is cut at F in extreme and mean ratio, and that its greater segment EF is equal to the side DE of the pentagon. Therefore, if two consecutive angles of an equilateral and equiangular pentagon, and so on. Which was to be shown.

Diagram. The equilateral, equiangular pentagon ABCDE inscribed in a circle, with the diagonals DB and CE drawn, cutting one another at the interior point F.

- A (top vertex): pentagon vertex on the circle
- B (upper-left vertex): pentagon vertex on the circle
- E (upper-right vertex): pentagon vertex on the circle
- C (lower-left vertex): pentagon vertex on the circle

SCHOLIUM.

We shall also easily demonstrate that the line which subtends an angle of an equilateral and equiangular pentagon is parallel to the opposite side — that is, that BD is parallel to the side AE, and CE to the side AE. For let a circle be described about the pentagon. [Margin: k — *Elements* X.22] Since [...]

(Continuing the Scholium to Proposition 8 — that a diagonal of an equilateral, equiangular pentagon is parallel to the opposite side.)

both the two angles A and BCE, and the two angles ABC and AEC, are equal to two right angles. But A and ABC are equal to one another in an equiangular pentagon; therefore the remaining angles BCE and AEC are also equal. Since, then, A and BCE are together equal to two right angles, A and AEC will likewise be equal to two right angles; and consequently AB and CE will be parallel. Which is what was proposed. [Margin: l — I.28]

THEOR. 9. PROPOS. 9.

[Margin: ix]

If the side of the hexagon and the side of the decagon inscribed in the same circle be joined together, the whole line is cut in extreme and mean ratio, and its greater segment is the side of the hexagon.

In the circle ABC let AB be the side of the decagon, and to it in a straight line let there be added BE, equal to the radius of the circle and therefore to the side of the hexagon inscribed in the same circle. I say that the line EA is cut at B in extreme and mean ratio, and that its greater segment is EB, the side of the hexagon.

For draw from A, through the centre D, the diameter AC, and join the lines DB and DE. Now since the arc AB is a tenth part of the whole circumference of the circle, the arc of the semicircle will contain the arc AB five times; and consequently the arc BC will be four times the arc AB. [Margin: a — VI.33] Therefore the angle BDC will also be four times the angle ADB. Again, since the sides BD and BE are equal — being sides of the hexagon (for BE, the side of the hexagon, is equal to the radius BD, by the corollary to Prop. 15 of Book IV) — [Margin: b — I.5] the angles BDE and BED will be equal; [Margin: c — I.32] and since the exterior angle ABD is equal to them together, the angle ABD will be double the angle BED. [Margin: d — I.5] But the angle BAD is equal to the angle ABD, because of the equality of the sides DA and DB. Therefore the angle BAD too will be double the angle BED; and consequently the two angles DAB and DBA together will be four times the angle BED. [Margin: e — I.32] Since, then, the exterior angle BDC is equal to the angles DAB and DBA together, the angle BDC will be four times that same angle BED. But this same angle BDC was shown to be four times the angle ADB. Therefore the angles AED and ADB are equal. And so, since the two angles AED and DAE of triangle ADE are equal to the two angles ADB and BAD of triangle ABD, [Margin: f — I.32] the triangles ADE and ABD will

be equiangular. [Margin: g — VI.4] Therefore, as EA is to AD — that is, to EB, which is equal to AD — so is AD — that is, EB, equal to itself — to BA. And therefore the line EA is cut at B in extreme and mean ratio, and its greater segment EB is the side of the hexagon. Thus, if the side of the hexagon and the side of the decagon inscribed in the same circle be joined together, the whole line is cut in extreme and mean ratio, and its greater segment is the side of the hexagon. Which was to be demonstrated.

Diagram. A circle with centre D and horizontal diameter running from C (at the left) through D to A (at the right). Point B lies on the upper-right of the circle; point E lies above and outside the circle, on the straight line AB produced (A–B–E collinear). AB is the side of the decagon; BE, its rectilinear extension, is the side of the hexagon (= radius). The radii DB and DE are drawn.

- C (left end of diameter): endpoint of diameter AC
- D (centre): centre of the circle
- A (right end of diameter): where the diameter meets the decagon side
- B (upper right, on circle): junction of decagon side AB and hexagon side BE
- E (top, outside circle): far end of the joined line, EB = hexagon side

SCHOLIUM.

Now since we demonstrated, at Prop. 5 of this book, that if the lesser segment of a line cut in extreme and mean ratio be subtracted from the greater segment, the greater segment too is cut in extreme and mean ratio, and that its greater segment is the lesser segment subtracted — and since here it has been shown that the side of the hexagon joined with the side of the decagon is cut in extreme and mean ratio — it follows that if the side of the hexagon be cut in extreme and mean ratio, its greater segment is the side of the decagon. For if this, which is the greater segment, be subtracted from the side of the hexagon, the side of the hexagon will have been divided in extreme and mean ratio, as we showed at Prop. 5 of this book. This, however, we shall demonstrate otherwise at Book XIV, Prop. 4.

The converse of this theorem too we shall easily demonstrate, along with Campanus. Namely:

If the greater segment of a line divided in extreme and mean ratio be the side of the hexagon of some circle, the lesser segment will be the side of the decagon of the same circle. And if the lesser segment be the side of the decagon of some circle, the greater segment will be the side of the hexagon of the same circle.

Let AB be divided in C in extreme and mean ratio, and let AC first be the side of the hexagon of the circle BCD. I say that the lesser segment CB is the side of the decagon of the same circle. For let BC be fitted into the circle, so that CA falls outside the circle. And, the diameter BED being drawn from B through the centre E, let the lines EA and EC be joined. Now since, as AB is to AC, so is AC to CB; and AC, the side of the hexagon, is equal to the radius EB, by the corollary to Prop. 15 of Book IV; it will also be that, as AB is to BE, so is EB to BC. [Margin: h — VI.6] Therefore the triangles ABE and EBC will be equiangular, since they have the sides about the common angle B proportional; and the angle A will be equal to the angle BEC. Again, since the sides CA and CE are equal — being sides of the hexagon — [Margin: i — I.5] the angles CAF [recte: CAE — no point F occurs in this figure] and CEA will be equal; [Margin: k — I.32] and since the exterior angle BCE is equal to them, BCE will be double the angle A. [Margin: l — I.5] But the angle CBE is equal to the angle BCE, because of the equality of the sides EB and EC. Therefore CBE too will be double the angle A; and consequently the two angles BCE and CBE together will be four times that same angle A. [Margin: m — I.32] Since, then, the exterior angle CED is equal to the angles BCE and CBE together, the angle CED too will be four times that same angle A, and therefore four times the angle BEC, which was shown equal to angle A. [Margin: n — VI.33] Therefore the arc CD will be four times the arc BC; and consequently the arc of the semicircle BCD will be five times that same arc BC, and so the whole circumference of the circle will be ten times the arc BC. Therefore the line BC is the side of the decagon.

Next, let CB, the lesser segment, be the side of the decagon of the circle BCD. I say that the greater segment AC is the side of the hexagon of the same circle. For let BC again be fitted into the circle BCD, and let the diameter BED be drawn. Then, with the interval AC, let the circle CFG be described, whose diameter is CAG; and by the corollary to Prop. 15 of Book IV, AC will be the side of the hexagon of the circle CF. Now since AB has been cut in C in extreme and mean ratio, and the greater segment AC is the side of the hexagon of the circle CFG, it will be, as has already been shown, that the lesser segment CB is the side of the decagon of the same circle CFG.

Diagram. A woodcut block holding two circles side by side, for the two cases of the converse. *Left circle:* centre E, horizontal diameter D (left)–E (centre)–B (right); a regular decagon is inscribed; C lies on the upper-right of the circle; A lies above and outside the circle (CA produced falls outside). The radii EA and EC are drawn, with the chord BC (decagon side). *Right circle* (circle CFG): centre A, horizontal diameter G (left)–A (centre)–C (right); a regular decagon is inscribed; F lies on the upper-right of the circle.

- Left circle — D (left): end of diameter; E (centre); B (right): end of diameter; C (upper right, on circle); A (top, outside): apex where CA is produced
- Right circle — G (left end of diameter); A (centre); C (right end of diameter); F (upper right, on circle)

(The demonstration of the second case concludes at the top of the following page, where this two-circle figure is repeated.)

(p. 542 — running header "EVCLID. GEOM." The two-circle converse figure of the preceding page is repeated at the top of this column.)

Diagram. A repetition of the two-circle converse figure from the previous page, placed here to accompany the concluding text. *Left circle:* centre E, diameter D–E–B, with C on the upper right and A above and outside; decagon inscribed. *Right circle:* centre A, diameter G–A–C, with F on the upper right; decagon inscribed.

- Right circle — G (left), A (centre), C (right), F (upper right)

[Margin: o — III.31] [Margin: p — I.36 [?]] (sense: the sides BD, CG proved equal — perhaps I.26)]

...the lesser segment CB, the side of the decagon of the same circle CFG. Let there therefore be described, in the circle CFG, the equilateral and equiangular decagon CFG; likewise in the circle BCD, the equilateral and equiangular decagon BCD; and the sides BC, CF will be equal to one another. Now since, if the lines CD and FG be joined, the angles CDB and FGC are equal — as we showed in the scholium to Prop. 22 of Book III, because they stand on similar arcs BC, CF, namely tenth parts of the circumferences — and since the angles BCD and CFG in the semicircles are also equal, [Margin: o — III.31] being of course right angles: the sides BD and CG too will be equal to one another. [Margin: p — I.36 [?]] For this reason, since the diameters BD and CG are equal, the circles BCD and CFG will also be equal. And consequently, since the line AC is the side of the hexagon of the circle CFG, that same line AC will also be the side of the hexagon of the circle BCD. Which is what was proposed.

THEOR. 10. PROPOS. 10.

[Margin: x]

If an equilateral pentagon be inscribed in a circle, the side of the pentagon is equal in square [potest] to the side of the hexagon and the side of the decagon inscribed in the same circle.

In the circle $ABCDE$, whose centre is F , let an equilateral pentagon be inscribed. I say that the square on the side AB is equal to the square on the side of the hexagon together with the square on the side of the decagon of the same circle. For draw the diameter AFG , and join the line FB . Then, the arc AB being bisected at H , join the lines AH , BH , and FH , this last cutting the line AB at I ; and the line AH will be the side of the decagon, and BF the side of the hexagon. Again, the arc AH being bisected at K , join the line FK , cutting the line AH at L and the line AB at M , the point to which the line HM is drawn.

Now since the arcs AH and BH are equal, [Margin: a — III.27] the angles standing on them, AFH and BFH , will be equal. Therefore, since the sides AF and FI of triangle AFI are equal to the sides BF and FI of triangle BFI , and the angles contained by them are also equal, [Margin: b — I.4] the bases AI and BI will be equal, and the angles AIF and BIF will be right angles. And by the same reasoning the lines AL and HL will be equal, and the angles ALF and HLF right angles. Next, if from the equal semicircles $ABCG$ and $AEDG$ there be taken the equal arcs ABC and AED , the arcs CG and DG will be left equal to one another; and so the arc CG will be half the arc CD . But the arc AH is likewise half the arc AB . Therefore, since the arcs AB and CD are equal, their halves, the arcs CG and AH , will also be equal; and consequently, since the arc AH is double the arc HK , the arc CG will also be double that same arc HK . In the same way, since the arcs AB and BC are equal, and the arc AB is double the arc BH , the arc BC too will be double that same arc BH . Therefore the arcs CG and BC are equimultiples — namely doubles — of the arcs HK and BH ; [Margin: c — V.1] and hence the whole arc BG will also be double the whole arc BK , [Margin: d — VI.33] and therefore the angle BFG too will be double the angle BFK . [Margin: e — III.20] But since this same angle BFG , at the centre, is also double the angle FAB , the angles BFM and FAB will therefore be equal; [Margin: f — I.32] and consequently the triangles ABF and FBM , since they have the angles FAB and MFB equal and the angle ABF common, will be equiangular. [Margin: g — VI.4] Therefore, as AB is to BF , so is BF to BM ; [Margin: h — VI.17] and hence the rectangle contained by AB and BM will be equal to the square on the line BF .

Again, since the sides AL and LM of triangle ALM are equal to the sides HL and LM of triangle HLM , and the angles contained by them equal, namely right angles, [Margin: i — I.4] the bases AM and HM , and the angles LAM and LHM , will be equal. [Margin: k — I.5] But the angle LAM is equal to the angle HBA , because the sides HA and HB are equal. Therefore the angle LHM too will be equal to that same angle HBA ; [Margin: l — I.32] and consequently the triangles ABH and AHM , since they have the angles ABH and AHM equal and the angle HAM common, will

be equiangular. [Margin: m — VI.4] For this reason, as AB is to AH, so is AH to AM; [Margin: n — VI.17] and hence the rectangle contained by AB and AM will be equal to the square on the line AH. But it was also shown that the rectangle contained by AB and BM is equal to the square on the line BF. Therefore the rectangles contained by AB, BM and by AB, AM together are equal to the squares on the lines BF and AH. [Margin: o — II.2] But the rectangles contained by AB, BM and by AB, AM together are equal to the square on the line AB. Therefore the square on the line AB, namely the side of the pentagon, is equal to the squares on the lines BF and AH, that is, on the side of the hexagon and the side of the decagon. If, therefore, an equilateral pentagon be inscribed in a circle, and so on. Which was to be demonstrated.

Diagram. A circle with centre F in which is inscribed the equilateral pentagon ABCDE: A at the top, B at the upper left, E at the upper right, C at the lower left, D at the lower right. The vertical diameter runs A–F–G, G being the lowest point of the circle. The arc AB is bisected at H (on the circle, upper left); the arc AH is bisected at K (near A). The line FH cuts AB at I; the line FK cuts AH at L and AB at M. The construction lines AH, BH, FH, FK, HM and the radius FB are drawn.

- A (top): pentagon vertex, top of diameter
- B (upper left): pentagon vertex
- C (lower left): pentagon vertex
- D (lower right): pentagon vertex
- E (upper right): pentagon vertex
- F (centre): centre of the circle
- G (bottom): lower end of diameter AFG
- H (upper left, on circle): midpoint of arc AB
- K (near A, on circle): midpoint of arc AH
- I (on AB): foot of FH on AB
- L (on AH): foot of FK on AH
- M (on AB): foot of FK on AB

COROLLARIVM I.

From this it follows that a straight line which from the centre bisects any arc also bisects the line subtended to that arc, and at right angles. For it was shown that the line FH, because it bisects the arc AB, also bisects the line AB at I, and at right angles. And the demonstration is the same in the remaining cases.

COROLLARIUM II.

It is likewise clear that a diameter of the circle drawn from any angle of the pentagon bisects both the arc which the side of the pentagon opposite to that angle subtends, and the opposite side itself, and at right angles.

(p. 543 — running header "LIBER XIII.")

For it has been demonstrated that the diameter AG, drawn from the point A, bisects the arc CD which the opposite side CD subtends. Therefore, by the aforesaid corollary, since it passes through the centre, it will also cut the side CD in two, and at right angles. The same demonstration will hold in every equilateral polygon inscribed in a circle, whenever the number of sides is odd, as is evident.

SCHOLIUM.

Since, at the end of Book IV, we handed down a certain construction from Ptolemy by which, in one and the same operation, both an equilateral pentagon and an equilateral decagon are described in a given circle, and postponed its demonstration to this place, it must now be demonstrated by us in a few words. Let then a circle ABC be given, whose centre is D. The diameter BC being drawn, let DA be erected perpendicular to BC. Then, the radius CD being bisected at E, draw the line EA, and cut off EF equal to it, and join the line AF. I say that the line AF is the side of the pentagon, and DF the side of the decagon. For since CD is bisected at E, and DF is added to it, [Margin: p — II.6] the rectangle contained by CF and DF, together with the square on the line DE, will be equal to the square on the line EF, and therefore to the square on the line EA, which is equal to EF. [Margin: q — I.47] But the square on the line EA is equal to the squares on the lines AD and DE. Therefore the rectangle contained by CF and DF, together with the square on the line DE, is equal to the squares on the lines AD and DE; and consequently, the common square on the line DE being taken away, the rectangle contained by CF and DF will be left equal to the square on the line AD, that is, to the square on the line CD. [Margin: r — VI.17] For this reason it will be, as CF is to CD, so CD to DF; and therefore the line CF will be divided at D in extreme and mean ratio. Since, then, the greater segment CD is the side of the hexagon of the circle ABC, by the corollary to Prop. 15 of Book IV, the lesser segment DF will be the side of the decagon of the same circle, as we demonstrated at Prop. 9 of this book. [Margin: s — "X.10" as printed; recte XIII.10 (Prop. 10 of this book)] Again, since the square on the side of the pentagon of the same circle is equal to the square on the side of the hexagon AD together with the square on the side of the decagon DF; [Margin: t — I.47] and since the square on the line AF is equal to the squares on the lines AD and DF; the square

on the side of the pentagon will be equal to the square on the line AF; and therefore the line AF is equal to the side of the pentagon. Which is what was proposed.

Diagram. A circle with centre D and horizontal diameter B (left)–D–C (right). Point A is at the top of the circle; DA is the vertical radius, perpendicular to BC. On the diameter, between D and C, E is the midpoint of DC; F lies to the left of D (with EF = EA cut off). From A a fan of lines is drawn down to B, F, D, E and C. AF is the side of the pentagon; DF the side of the decagon.

- A (top, on circle): apex
- B (left end of diameter)
- C (right end of diameter)
- D (centre)
- E (between D and C): midpoint of the radius DC
- F (between B and D): point with EF = EA

THEOR. 11. PROPOS. 11.

[Margin: xij]

If an equilateral pentagon be inscribed in a circle having a rational diameter, the side of the pentagon is the irrational line called minor.

In the circle ABCDE, having a rational diameter, let the equilateral pentagon ABCDE be inscribed. I say that its side AB is the irrational line called minor. For draw, through the centre F, the diameters AG and BH; let AG cut the side CD at I; and join the lines AC and AH, of which AC cuts the diameter BH at K. From the radius FH cut off also its fourth part FL; likewise from the line AC its fourth part CM. Now since the diameter BH is set down as rational, FL and BF too will be commensurable with it — being rational aliquot parts of it; [Margin: a — X.16] and therefore the whole line BL, compounded of them, since it is commensurable with each of FL and BF, will be rational.

Again, since the line FB, drawn from the centre, cuts the arc AC in two at B, it will also cut the line AC in two at L, and at right angles, by Corollary 1 of the preceding proposition. And the line AG cuts the line CD at I in two, and at right angles, by Corollary 2 of the same proposition. Therefore the triangles ACI and AFK, since they have the angles AIC and AKF right angles and the angle CAI common, [Margin: b — I.32] will be equiangular with one another. [Margin: c — VI.4 ?] (printed digit reads "3") For this reason it will be, as CI is to CA, so FK to FA — or to FH, which is equal to FA. [Margin: d — V.15] But as CA is to FH, so is

CM, the fourth part of CA, to FL, the fourth part of FH. Therefore it will be, as CI is to FK, so CM to FL; and, alternately, as CI is to CM — that is, as CD, the double of CI, is to CK, the double of CM — so FK to FL; and, by composition, as CD and CK together are to CK, so FK and FL together — namely the line KL — to FL. [Margin: e — VI.22] And therefore it will be, as the square on the line compounded of CD and CK is to the square on the line CK, so the square on the line KL to the square on the line FL. Now since, if AC be cut in extreme and mean ratio (the line BD being drawn), [Margin: f — "III.8" as printed; recte XIII.8] its greater segment is equal to the side of the pentagon, namely to CD; the square on the line compounded of CD, the greater segment, and [Margin: g — "III.1" as printed; recte XIII.1] CK, the half of the whole, will be five times the square on the line CK, the half namely of the whole. Therefore the square on the line KL too will be five times the square on the line FL, [Margin: h — X.6] and hence the square on the line KL will be commensurable with the square on the line FL; and consequently the lines KL and FL too will be commensurable, at least in square. But FL was shown to be rational. Therefore KL too will be rational.

Next, since FL is one part of the four of which BF is four, and therefore FL is one part of the five of which BL is five, the square on the line BL will be twenty-five of the parts of which the square on the line FL is one (as is plain in these numbers, 1, 5, 25; [Margin: i — VI.20] for squares have the ratio of their sides doubled). But the square on the line KL was shown to be five of the parts of which the square on the line FL is one. Therefore, of the parts of which the square on the line BL is twenty-five, the square on the line KL is five; and consequently the square on the line BL will be five times the square on the line KL. Since, then, the squares on the lines BL and KL do not have to one another the ratio which a square number has to a square number (as is plain from the corollary to Prop. 24 of Book VIII, for their ratio is that of 25 to 5, or 5 to 1), [Margin: k — X.9] the lines BL and KL will be incommensurable in length; and so, since they have been shown to be rational, they will be rational commensurable in square only. Therefore, if from the rational line BL there be taken the rational line KL, commensurable in square only, [Margin: l — X.74] the remainder BK will be irrational — the irrational called an apotome — and KL will be congruent with it.

Book XIII (continued)

Proposition 11 (continued) — the side of the equilateral pentagon inscribed in a circle with rational diameter is the *minor*

Now the straight line BL is capable of more than the straight line KL by the square on N. Since, therefore, the square on BL equals the sum of the squares on KL and N, and since the square on BL was 5 such parts while the square on KL was 1 such part, the remaining square on N will be 4 of those parts of which the square on BL is 5. Consequently the squares on BL and N will have to one another the ratio of a number to a number, and so they will be commensurable [Margin: (m) X.6]; and therefore the lines BL and N are themselves commensurable — at least in square. But BL was shown to be rational. N, then, will also be rational.

Now the squares on BL and N do not have to one another the ratio of a square number to a square number — as is clear from the corollary to Proposition 24 of Book VIII, since their ratio is that of 5 to 4. It follows that the lines BL and N are incommensurable in length [Margin: (n) X.9], and hence rational and commensurable in square only. Therefore, since the whole line BL is commensurable in length with the rational line BH (for BH is 8 such parts of which BL is 5), and is capable of more than its commensurable KL by the square on a line, N, incommensurable with BL in length (as was shown), BK will be a fourth apotome, by the definition.

Finally, since the straight line AB is a mean proportional between BH and BK — by the corollary to Proposition 8 of Book VI, because the triangle ABH has the angle BAH right [Margin: (o) III.31], from which AK is drawn perpendicular to the base — the square on AB will equal the rectangle contained by BH and BK [Margin: (p) VI.17]. And so, since the straight line AB is capable of the area contained by the rational line BH and the fourth apotome BK, AB will be a *minor* line [Margin: (q) X.95], and so on. If, therefore, in a circle having a rational diameter, and so forth. Which was to be demonstrated.

[Margin: xij [?] (outer, vulgate proposition number)]

THEOR. 12. PROPOS. 12.

If an equilateral triangle be inscribed in a circle, the side of the triangle is in square triple the line drawn from the center of the circle [i.e. the radius].

Let an equilateral triangle ABC be inscribed in the circle ABC whose center is D. I say that the square on the side AB is triple the square on the radius.

Diagram. A circle with center D and an inscribed equilateral triangle ABC; the vertical diameter runs from the top vertex A through the center D and the foot F down to the point E at the bottom of the circle. Radii and connecting lines are drawn.

- A (top): upper vertex of the triangle
- B (lower left): left base vertex
- C (lower right): right base vertex
- D (center): center of the circle
- F (on BC, below D): foot where the diameter meets the base BC
- E (bottom): lower end of the diameter, diametrically opposite A

Draw the diameter AE, which — by the corollary to Proposition 10 of this Book — bisects the arc BC at E and also bisects the straight line BC at right angles in the point F. Since the arc BC is a third part of the whole circumference, the arc BE will be a sixth part of the same circumference; and therefore the chord BE, once joined, will be the side of a hexagon and equal to the radius of the circle, by the corollary to Proposition 15 of Book IV.

This can also be shown as follows. The semicircle ABE contains three sixth-parts of the whole circle; but the arc AB, being a third part of the whole circle, comprehends two sixth-parts of it. Therefore the arc BE is a sixth part of the same circle, and accordingly the chord BE is the side of a hexagon and equal to the radius DE, by the corollary to Proposition 15 of Book IV.

Since, then, the square on AE equals the sum of the squares on AB and BE [Margin: (a) I.47] — because the angle ABE, being in a semicircle, is right [Margin: (b) III.31] — and since the square on AE is quadruple the square on BE (by the scholium to Proposition 4 of Book II, seeing that the line AE is double the line BE), the squares on AB and BE together will also be quadruple the square on that same line BE. And therefore, of whatever 4 parts the squares on AB and BE together consist, the square on BE will be 1 such part; and accordingly the square on AB will be 3 such parts. Thus the square on AB is triple the square on BE, which is equal to the radius. If, therefore, an equilateral triangle be inscribed in a circle, and so forth. Which was to be shown.

COROLLARIVM I.

It follows from this that the diameter of the circle is in square sesquitertiate [4:3] to the side of the equilateral triangle inscribed in that circle. For since the side AB was shown to be in square triple the radius AD, then, setting the square on AB at 3, the square on AD will be 1; and so the square on AE — which, by the scholium to Proposition 4 of Book II, is quadruple the square on AD — will be 4. Thus the square on AE is sesquitertiate to the square on AB, that is, it has the ratio of 4 to 3.

Diagram. The same construction repeated for the corollary: a circle with center D and inscribed equilateral triangle ABC, with the vertical diameter through A, D, F, and E.

- A (top): upper vertex
- B (lower left): left base vertex
- C (lower right): right base vertex
- D (center): center of the circle
- F (on BC): foot of the perpendicular from A on BC
- E (bottom): lower end of the diameter

And since, by the corollary to Proposition 8 of Book VI, as AE is to AB, so is AB to AF, the perpendicular AF of the equilateral triangle AB — dropped from one angle to the base — will likewise be in square sesquitertiate [to the whole]; this, however, will be demonstrated otherwise by Euclid in Book XIV, Proposition 12.

COROLLARIVM II.

Hence it can also easily be gathered that the radius DE is bisected at F by the side BC of the triangle [Margin: (c) I.47]. For since the square on AB is triple the square on BE, if the square on AB be set at 12 parts, the square on BE will be 4 such parts. But the square on BE equals the sum of the squares on BF and FE.

Therefore the squares on BF and FE will also be 4 such parts. But — because the square on AB is quadruple the square on BF, by the scholium to Proposition 4 of Book II (for AB is double BF) — the square on BF is 3 of those parts. Hence the square on FE will be 1 such part; and accordingly the square on BE, that is, the square on DE (which equals it), will be quadruple the square on FE. Therefore, by the scholium to Proposition 4 of Book II, the line DE will be double FE. And so DE is bisected at F.

SCHOLIUM.

This corollary will nevertheless be demonstrated otherwise by the following theorem.

If an equilateral triangle be inscribed in a circle, the diameter drawn from one angle will bisect both the angle and the opposite side, and moreover at right angles; and the radius in turn will be bisected, and at right angles, by the opposite side.

Diagram. A circle with center D and inscribed equilateral triangle ABC; the vertical diameter AE passes through A, the center D, the foot F on BC, and E at the bottom. The chords BD, CD, BE, and CE are drawn as well.

- A (top): upper vertex
- B (left): left base vertex
- C (right): right base vertex
- D (center): center of the circle
- F (on BC, below D): intersection of the diameter with the base BC
- E (bottom): lower end of the diameter

Let an equilateral triangle ABC be inscribed in the circle ABC whose center is D. I say that the straight line AE drawn through the center D — that is, the diameter — bisects both the angle BAC and the side BC, and that at right angles; and that the radius DE is bisected by the side BC, and at right angles.

For, when the straight lines BD, CD, and BE have been drawn: since the sides AB and AD are equal to the sides AC and AD of the triangle CAD, and the bases BD and CD are equal as well, the angles BAD and CAD will be equal [Margin: (d) I.8]. Which is the first point.

Next, since the sides AB and AF of the triangle BAF are equal to the sides AC and AF of the triangle CAF, and the angles contained by them have been shown equal, the bases BF and CF, and the angle at F, will be equal [Margin: (e) I.4]; and therefore the angles at F are right. Which is the second point.

Finally, since the angles BAE and CAE have been demonstrated to be equal, the arcs BE and CE will also be equal [Margin: (f) III.26]. And so, since the arc BEC is a third part of the circumference, BE will be a sixth part of it; and accordingly the chord BE is the side of a hexagon, and thus equal to the radius BD, by the corollary to Proposition 15 of Book IV. Therefore the angles BDE and BED will be equal [Margin: (g) I.5]. Since, then, the angles BDF and BFD of the triangle BDF are

equal to the angles BEF and BFE of the triangle EBF, and the side BF is common, the sides DF and EF will also be equal [Margin: (h) I.26]. Which is the third point.

PROBL. 1. PROPOS. 13.

[Margin: xiiij (outer, vulgate proposition number)]

To construct a pyramid [regular tetrahedron], to comprehend it in a given sphere, and to demonstrate that the diameter of the sphere is in square sesquialterate [3:2] to the side of the pyramid itself.

Let AB be the diameter of the given sphere. About it describe the semicircle ABC, and from AB cut off a third part BD, so that AD is double DB, while AB is triple that same DB and sesquialterate [3:2] to AD. Then draw DC perpendicular to AB, and join the straight lines AC and BC. With the interval of the straight line HE, equal to DC itself, describe a circle EFG whose center is H, and in it inscribe an equilateral triangle EFG; and join the straight lines HF and HG, which will each be equal to DC, since they are equal to HE, at whose interval the circle was described. Next, erect from H, perpendicular to the plane of the circle, the line HI, which is set equal to the straight line AD; and from I let the straight lines IE, IF, and IG be drawn down. I say that the solid contained by the four triangles FEG, IEF, IFG, and IEG is a pyramid, or tetrahedron.

Diagram. Left-hand figure: a semicircle on the diameter AB with apex C. Along the diameter, from left to right, lie A, then L (the midpoint / sphere-center), then D, then B; the perpendicular CD rises from D to the arc at C, and the chords AC and CB are drawn.

- A (left): left end of the diameter
- L (between A and D): midpoint of AB (later identified as the center of the sphere)
- D (between L and B): point dividing AB so that AD is double DB
- B (right): right end of the diameter
- C (apex, on the arc): foot of the perpendicular DC produced to the semicircle

Diagram. Right-hand figure: a circle carrying the plane projection of the tetrahedron. E is at the top, I at the upper right, H at the center; F is at the lower left and G at the lower right (the base triangle EFG with center H); K is at the bottom of the circle. Straight lines join I to E, F, and G, and E, F, G to one another and to H.

- E (top): a base vertex of the tetrahedron
- I (upper right): the apex of the tetrahedron
- H (center): center of the base circle
- F (lower left): a base vertex
- G (lower right): a base vertex
- K (bottom): lower end of the axis IK on the circle

For since the sides DA and DC of the triangle ADC are equal to the sides HI and HE of the triangle IHE, and the angles contained by them are right, by the hypothesis and by Definition 3 of Book XI, the base AC will be equal to the base IE [Margin: (a) I.4]. In the same way we shall show that this same straight line AC is equal to the lines IF and IG.

Again, since the three lines AD, DC, and DB are proportional, by the corollary to Proposition 8 of Book VI, it will follow — by the corollary to Proposition 20 of Book VI — that as AD is to DB, so is the square on AD to the square on DC; and *componendo*, as AB is to DB, so are the squares on AD and DC together to the square on DC. But the squares on AD and DC together are equal to the square on AC [Margin: (b) I.47]. Therefore it will also hold that as AB is to DB, so is the square on AC to the square on DC. And hence, since AB is triple DB, the square on AC will be triple the square on HE (since HE is equal to DC). But the square on EF is likewise triple the same square on HE [Margin: (c) XIII.12]. The square on AC, therefore, will be equal to the square on EF, and consequently the line AC to the line EF.

And so, since the line AC has also been shown equal to the lines IE, IF, and IG, the four triangles EFG, EFI, FGI, and GEI will be equilateral and equal to one another. Therefore the pyramid, or tetrahedron, is now constructed, its base being EFG and its vertex I. I say that this pyramid is comprehended in the given sphere, whose diameter is AB, and that the diameter of the sphere AB is in square sesquialterate to the side EF, or AC.

Let the perpendicular IH be extended as far as K, so that HK is equal to DB and the whole IK equal to the whole AB. Since, then, the three lines AD, DC, and DB are proportional, and the three lines IH, HE, and HK are respectively equal to them, IH, HE, and HK will also be proportional. And so, since HE is perpendicular to IK and is a mean proportional between IH and HK, the semicircle described about IK in the plane of the lines IK and HE will pass through E — as will presently be shown. By the same reasoning, the semicircle described about the same line IK in the plane of the lines IK and HF will pass through F, and the

semicircle described about the same IK in the plane of the lines IK and HG will pass through G. Therefore any one of these semicircles, when carried around

Diagram. The Proposition-13 pair repeated at the head of the page. Left: the semicircle on AB with apex C, the points A, L, D, B along the diameter and the perpendicular CD. Right: the circle with the tetrahedron projection — E (top), I (upper right), H (center), F (lower left), G (lower right), K (bottom).

- Left figure — A (left), L (midpoint), D, B (right); C (apex)
- Right figure — E (top), I (upper right), H (center), F (lower left), G (lower right), K (bottom)

— carried around, the diameter remaining fixed, will describe a sphere that comprehends the constructed tetrahedron, since it passes through all its angles E, F, G, and I. Since, then, this described sphere is equal to the given sphere — because the diameter IK is set equal to the diameter AB — the same tetrahedron will be comprehended by the given sphere.

Now, since the three straight lines AB, AC, and AD are proportional, by the corollary to Proposition 8 of Book VI, it will follow — by the corollary to Proposition 20 of Book VI — that as AB is to AD, so is the square on AB to the square on AC. But the straight line AB is sesquialterate to the straight line AD, for of whatever 3 parts AB consists, AD is 2. Therefore the square on AB will also be sesquialterate to the square on AC; and accordingly, since AB is the diameter of the sphere and AC is equal to the side EF of the pyramid, it is clear that the diameter of the sphere is in square sesquialterate to the side of the tetrahedron, or pyramid. We have therefore constructed a pyramid and comprehended it in the given sphere, and so on. Which was to be done.

LEMMA.

That the semicircle described about IK, in the plane of the lines IK and HE, passes through E will easily be demonstrated by the following theorem.

If a perpendicular be drawn to a straight line such that it is a mean proportional between the segments of the line, the semicircle described about that straight line will pass through the extreme point of the perpendicular line.

Diagram. A semicircle on the diameter, with B, C, and A along it (B and C at the left, A at the right); the perpendicular at C rises to D on the arc. Two dotted arcs

are drawn to represent a semicircle passing short of, or beyond, D, meeting the perpendicular at the hypothetical point E (marked once above D and once below).

- B (left): one end of the diameter
- C (on the diameter, near B): foot of the perpendicular
- A (right): other end of the diameter
- D (on the true arc, above C): extreme point of the perpendicular
- E (upper and lower, dotted): hypothetical point where a wrongly-drawn semicircle would meet the perpendicular

Let CD be perpendicular to AB and a mean proportional between AC and CB. I say that the semicircle described about AB passes through D. For if it should pass short of D, or beyond it — namely through the point E — then CE too would be a mean proportional between AC and CB, by the corollary to Proposition 13 of Book VI. Hence both the square on CD and the square on CE would be equal to the rectangle contained by AC and CB [Margin: (d) VI.17]; and accordingly the squares on CD and CE would be equal to one another, and the very lines CD and CE would be equal — the part and the whole. Which is absurd. Therefore the semicircle passes through D.

Hence it is manifest that the semicircle described in the upper figure about IK, in the plane of the lines IK and HE, passes through E, since HE is perpendicular to IK and a mean proportional between IH and HK.

COROLLARIVM I.

Hence we shall easily gather that the diameter of the sphere is in square quadruple-and-sesquialterate [9:2] to the radius of the circle described about the base of the pyramid. For since the diameter of the sphere AB was shown to be in square sesquialterate to the side EF of the pyramid, the square on EF will be 6 such parts of which 9 is the square on AB. But of whatever 6 parts the square on EF consists, 2 is the square on HE [Margin: (e) XIII.12], because the square on EF is triple the square on HE. Therefore, of whatever 9 parts the square on AB consists, the square on HE will be 2 such parts; and accordingly the diameter of the sphere AB is in square quadruple-and-sesquialterate to the radius HE, since the ratio of the squares is that of 9 to 2.

Diagram. The Proposition-13 pair repeated once more for the corollaries. Left: the semicircle on AB with A, L, D, B along the diameter and apex C. Right: the circle with the tetrahedron projection — E (top), I (upper right), H (center), F (lower left), G (lower right), K (bottom).

- Left figure — A (left), L (midpoint), D, B (right); C (apex)
- Right figure — E (top), I (upper right), H (center), F (lower left), G (lower right), K (bottom)

COROLLARIUM II.

Again, the perpendicular dropped from the center of the sphere to the plane of the base of the pyramid will be a sixth part of the diameter of the sphere and a third part of the radius. For let L be the center of the semicircle ABC; then L will also be the center of the sphere. I say that the straight line LD — which is indeed drawn perpendicular from the center of the sphere to the base EFG, since AD is equal to IH and therefore the point D is the same as H, just as L is the same as the center of the sphere — is a sixth part of the diameter of the sphere, namely of the line AB, and a third part of the radius AL. For since AD is double DB: of whatever 4 parts AD consists, DB will be 2, and accordingly the whole AB will be 6 such parts, and the radius AL will be 3. And so, if AD is 4 and AL is 3, LD will be 1; and therefore LD will be a sixth part of the line AB, which was 6 of those same parts, and a third part of the line AL, which was 3 of those same parts.

Likewise, the altitude of the pyramid HI will contain two-thirds of the diameter itself. For HI is the same as AD, which contains two-thirds of the diameter, by the construction.

Again, if the square on the diameter be set at 9 parts, the square on the altitude of the pyramid will be 4 such parts. For the ratio of 9 to 4 is the duplicate of the ratio of 3 to 2, as here appears: 9, 6, 4.

[Scholium to Proposition 13, continued]

If from some material four equal equilateral triangles are made and arranged as this figure shows, then when they are properly folded together a tetrahedron is easily built up from them in its full solidity. This procedure — together with the four that follow, by which the remaining four regular solids are fashioned in any tangible material — we have taken from Albrecht Dürer [Alberto Durero], no undistinguished writer.

Diagram. The net (unfolding) of the tetrahedron: a strip of four equilateral triangles laid edge to edge in a band (alternately pointing up and down), which folds up into the solid. Uncaptioned; no letter-labels.

PROBL. 2. PROPOS. 14.

[Margin: xiv.]

To construct an octahedron and to comprehend it in a sphere (as was done for the pyramid too), and to demonstrate that the square on the sphere's diameter is double the square on the octahedron's own edge.

Let AB be the diameter of the sphere that comprehends the pyramid already constructed, and about it let the semicircle ACB be described; from the center D let the perpendicular DC be drawn to AB, and let the straight lines AC, BC be joined [a], which will be equal to one another. [Margin (a): Elements I.4] Now, taking a straight line EF equal to AC or BC, let the square EFGH be described upon it, and in it let the diagonals EG, FH be drawn, cutting one another at I; then the straight lines IE, IF, IG, IH will be equal, since they are radii of the circle described about the square, as was demonstrated in Book IV. Next, from I let a perpendicular KL be erected to the plane of the square on both sides, and let IK, IL be set equal to IE; and finally, from K and L let the straight lines KE, KF, KG, KH, LF, LE, LH, LG be drawn to the corners of the square. I say that the solid contained by the eight triangles KEF, KFG, KGH, KEH; LFE, LEH, LHG, LFG is the octahedron that is sought.

For the sides EI, IK of triangle EIK are equal to the sides EI, IH of triangle EIH, and the angles they contain are right — angle EIK by definition 3 of Book XI, and angle EIG [b] because it is equal to the successive angle GIH, on account of the equality of the sides EI, IH, GI, IH and of the bases EH, GH. [Margin (b): Elements I.8] Therefore [c] the base EK will be equal to the base EH; and in the same way KH will be equal to that same EH; and so triangle KEH will be equilateral. [Margin (c): Elements I.4] By the same reasoning we shall conclude that the remaining triangles are equilateral, and hence equal to triangle KEH, since their sides are equal, one by one, to the sides of the square EFGH. So now an octahedron has been constructed from eight equilateral and equal triangles. I say that this octahedron is comprehended by the sphere of diameter AB — the very sphere by which the constructed pyramid too is comprehended — and that the square on the sphere's diameter AB is double the square on the edge EF, or AC.

For since IE is perpendicular to KL (by definition 3 of Book XI) and is a mean proportional between the segments KI, IL — because the three straight lines KI, IE, IL are equal and therefore have the same ratio — the semicircle described about KL in the plane of the straight lines KL, IE will pass through the point E, by the lemma of the preceding proposition. By the same reasoning the semicircle described about the same KL in the plane of the straight lines KL, IF will pass through the point F; and the same must be said of the points G, H. Therefore each of these semicircles, carried around while the diameter KL remains fixed, will

describe a sphere that comprehends the constructed octahedron, since it passes through all of its vertices. Now this sphere is equal to the given sphere whose diameter is AB. (For since the straight lines AC, EF are equal, their squares are equal; and since the square on AC is double the square on AD, just as the square on FE is double the square on EI, the straight lines AD and EI — that is, KI — the radii, will be equal. Therefore the whole diameters AB, KL will also be equal, and consequently their spheres will be equal.) Hence the same octahedron will be comprehended by the given sphere.

And since the square on AB [d] is equal to the squares on AC, BC, which are equal, the square on AB will be double the square on AC. [Margin (d): Elements I.47] Therefore, since AB is the diameter of the sphere and AC is a straight line equal to the octahedron's edge EF, it is clear that the square on the sphere's diameter is double the squares on the octahedron's edges. And so we have constructed the octahedron and comprehended it in a sphere, as we did the pyramid, and so on. Which was to be done.

Diagram. The defining semicircle for the octahedron construction: a semicircle standing on the diameter, with the right-triangle construction inscribed. Uncaptioned.

- A (base, left endpoint of the diameter)
- D (base, foot of the perpendicular / center)
- B (base, right endpoint of the diameter)
- C (apex of the semicircle, joined to A and B; CD is the perpendicular to the base)

Diagram. The octahedron drawn as a solid (hexagonal outline with internal diagonals), showing its six vertices and center.

- K (top apex)
- E (upper-left square vertex)
- H (upper-right square vertex)
- I (center, where the three diameters meet)
- F (lower-left square vertex)
- G (lower-right square vertex)
- L (bottom apex)

COROLLARIVM. I.

From what has been said it is clear that in the octahedron three diameters cut one another at right angles at the center of the sphere: namely KL, EG, FH, cutting one another at I. For all the angles at I have been shown to be right. And accordingly, since KI is at right angles to the lines EG, HE [e], it will also be at right angles to the plane EFGH drawn through them; [Margin (e): Elements XI.4] and therefore [f] the planes KFLH, ELGK, drawn through KI, will be at right angles to the plane EFGH. [Margin (f): Elements XI.8] Indeed, by the same reasoning — to sum the matter up briefly — the three planes EFGH, KFLH, ELGK will cut one another at right angles. These planes are squares, since all their sides are edges of the octahedron itself and therefore are equal to one another and contain right angles; for (since the square on the sphere's diameter is double the square on the octahedron's edge, as we have shown) the square on the diameter HF turns out equal to the squares on the octahedron's edges Fk, kH. [g] For thus it comes about that the angle FkH is right. [Margin (g): Elements I.48] And the same reasoning holds for the remaining angles.

COROLLARIVM. II.

The octahedron is divided into two similar and equal pyramids whose common base is the square EFGH, whose apexes are k and L, and whose altitudes, finally, are the radii Ik, IL: such are the pyramids EFGH-k and EFGHL. For the faces of the one are similar and equal to the faces of the other, as is evident, since they are equilateral and equal triangles, apart from the common base, which is a square equal to half the square on the sphere's diameter, as has been demonstrated.

COROLLARIVM. III.

If a tetrahedron and an octahedron are described in the same sphere, the square on the tetrahedron's edge will be sesquitertian (4:3) to the square on the octahedron's edge. For let the square on the sphere's diameter be divided into six parts. [h] Since, then, the sphere's diameter is in square sesquialter (3:2) to the tetrahedron's edge, the square on the tetrahedron's edge will be 4 of such parts as the square on the sphere's diameter is 6. [Margin (h): Elements XIII.13] Again, since the sphere's diameter is in square double the octahedron's edge, [i] the square on the octahedron's edge will be 3 of such parts as the square on the sphere's diameter is 6. [Margin (i): Elements XIII.14] Therefore, since the square on the tetrahedron's edge is 4 such parts of which the square on the octahedron's edge is 3, it is clear that the tetrahedron's edge is in square sesquitertian (4:3) to the octahedron's edge.

COROLLARIVM. IV.

Finally, since in the square EFGH the straight line EH is parallel to FG, and in the square ELGk the straight line Ek is parallel to GL, [k] the plane EHk drawn through EH, Ek will be parallel to the plane FGL drawn through FG, GL. [Margin (k): Elements XI.15] And since the same reasoning holds for the other faces of the octahedron, it follows that the opposite faces of the octahedron are parallel to one another.

SCHOLIVM.

If from some material eight mutually equal equilateral triangles are made and arranged as this figure shows, then when they are properly folded together an octahedron is easily built up from them in its full solidity, as Albrecht Dürer [Albertus Durerus] says.

Diagram. The net (unfolding) of the octahedron: eight equilateral triangles arranged in a folding pattern (a row of triangles with additional triangles above and below), which folds up into the solid. Uncaptioned; no letter-labels.

PROBL. 3. PROPOS. 15.

[Margin: xiiii.]

To construct a cube and to comprehend it in a sphere (as was done for the previous figures too), and to demonstrate that the square on the sphere's diameter is triple the square on the cube's own edge.

Let AB be the diameter of the sphere that comprehends the aforesaid figures, and about it let the semicircle ACB be described; and from AB let the third part BD be cut off, so that AB is triple BD. Then, DC having been drawn perpendicular to AB, let the straight lines AC, BC be joined. Upon a straight line EF equal to BC let the square EFGH be constructed, and upon it let the perpendiculars EI, Fk, GL, HM be erected, equal likewise to BC, whose ends are joined by the straight lines Ik, kL, LM, MI. Now since the straight lines EI, Fk are at right angles to the plane EFGH, [a] the straight lines EI, Fk will be parallel; and they are also equal, since each has been set equal to BC, that is, to EF. [Margin (a): Elements XI.6] Therefore [b] EF and Ik are parallel and equal; and so EFkI is a parallelogram, in which, since the lines EI, Ik, kF are equal to EF, all four lines turn out equal. [Margin (b): Elements I.33] Moreover [c] all four angles are right, since Elk, FkI are equal to the opposite right angles kFE, IEF. [Margin (c): Elements I.34] Therefore EFkI is a square. By the same reasoning FkLG, GLMH, HMIE will be squares; and hence IkLM too will

be a square, [d] since it is similar and equal to the opposite square EFGH. [Margin (d): Elements XI.24] For EL is a solid parallelepiped, [e] because its opposite planes are parallel, being drawn through mutually tangent parallel lines. [Margin (e): Elements XI.15] Therefore EL will be a cube. I say that it is comprehended by the sphere of diameter AB. For let the diameters Ek, FI, GM, HL of the opposite planes EFkI, GHML be drawn, and through them let the planes EkLH, FIMG be drawn. [f] Now since both the plane EkLH and the plane FIMG bisect the cube, each will pass through the center of the cube — by the scholium to proposition 39 of Book XI — namely through the point P, at which, by the corollary of the same proposition, all the diameters of the cube also bisect one another; [Margin (f): Elements XI.28] and therefore the common section of the planes, namely the straight line NO, will pass through the same point P. And since the planes EkLH, FIMG are rectangular — for since HE is perpendicular to the two straight lines EI, EF, on account of the squares EM, Ek, [g] it will also be perpendicular to the plane Ek, and therefore to the straight line Ek, by definition 3 of Book XI; so the angle HEk is right, and by the same reasoning the remaining angles in the plane EkLH will be right, as also the angles in the plane FIMG; therefore the planes EkLH, FIMG are rectangular — [Margin (g): Elements XI.4] and equal, since the sides of the one are equal to the sides of the other, their diameters EL, Hk, FM, GI will also be equal, as...

Diagram. The defining semicircle for the cube construction: a semicircle on the diameter with the right-triangle construction inscribed, adjoining the cube figure at right. Uncaptioned.

- A (base, left endpoint of the diameter)
- D (base, foot of the perpendicular)
- B (base, right endpoint of the diameter)
- C (apex of the semicircle, joined to A and B) — the printed glyph is foxed and resembles a "G"; read as C from the construction (semicircle ACB, lines AC, BC)
- E (base, to the right of B — the corner where the square/cube EFGH begins)

Diagram. The cube drawn as a solid, with all its face-diagonals and body-diagonals inscribed, showing the base square EFGH, the opposite square IkLM, the center P, and the two face-centers N, O. It is a dense figure; the readable vertex labels are:

- M (top rear corner)
- L (top right corner)

- N (center of the upper face)
- H (upper-left front corner)
- G (upper-right corner)
- P (center of the cube, where the body-diagonals meet)
- I (lower-left corner)
- K (lower-right corner; the "k" of the text)
- O (center of the lower face)
- F (bottom front corner)
- E (bottom-left corner, adjoining the semicircle)

as is evident from the scholium to proposition 24 of Book I. And accordingly the radii PE, PL, PH, PK; PF, PM, PG, PI will be equal. Therefore the semicircle described about EL from the center P, and carried around while the diameter EL remains fixed, will describe a sphere passing through all the vertices of the cube; and that this sphere is equal to the sphere of diameter AB will be demonstrated thus.

Since the square on EK [h] is equal to the equal squares on EF, FK, and therefore double the square on EF — that is, the square on KL — the squares on EK, KL will be triple the square on KL. [Margin (h): Elements I.47] Now [i] the square on EL is equal to the squares on EK, KL, because the angle EKL is right in the right-angled figure EkLH. [Margin (i): Elements I.47] Therefore the square on EL too will be triple the square on kL, that is, the square on BC. But the square on AB is triple that same square on BC. (For the three straight lines AB, BC, BD are proportional, by the corollary of proposition 8 of Book VI; and accordingly, by the corollary of proposition 20 of Book VI, as AB is to BD, so will the square on AB be to the square on BC. Since, then, AB is triple BD, the square on AB will also be triple the square on BC.) Therefore the squares on EL, AB are equal; and consequently the straight lines EL, AB themselves — the diameters, that is, of the spheres — and therefore their spheres too are equal.

And since it has been shown that the square on the diameter EL is triple the square on the cube's edge kL, it is clear that the square on the sphere's diameter is triple the square on the cube's edge. Wherefore we have constructed the cube and comprehended it in a sphere, and so on. Which was to be done.

COROLLARIVM. I.

From the demonstration of this problem it is clear that all the diameters of the cube are equal to one another and bisect one another at the center of the sphere;

and that by the same reasoning the straight lines joining the centers of opposite squares are bisected at the same center. For it has been demonstrated that the diameters of the cube EL, Hk, FM, GI are equal and bisect one another at the center P. That the straight line NO too, joining the centers N and O of the opposite squares GHMI, EFkI, is bisected at the same center P, will be shown as follows. The two angles OFP, OPF of triangle OFP are equal to the two angles NMP, NPM of triangle NMP: ([k] for the angle OFP is equal to the alternate angle NMP, [Margin (k): Elements I.29] between the lines FI, GM [l] which are parallel, being the common sections of the parallel planes EFkI, GHML; [Margin (l): Elements XI.16] and [m] the angle OPF is equal to its vertical angle NPM.) [Margin (m): Elements I.15] And the sides PF, PM adjacent to them are equal, being radii. Therefore the sides PO, PN will also be equal; and consequently the straight line NO will be bisected at P. And the same reasoning holds for the other lines joining the centers of the other opposite squares.

COROLLARIVM. II.

Again, the square on the diameter of the sphere, or of the cube, is equal to the squares on the edges of the tetrahedron and the cube taken together. [n] For the square on the tetrahedron's edge is 6 of such parts as the square on the diameter is 9; [Margin (n): Elements XIII.13] while [o] the square on the cube's edge is 3 of such parts as that same square on the diameter is 9. [Margin (o): Elements XIII.15] Therefore the square on the tetrahedron's edge and the square on the cube's edge together are 9 parts, just as the square on the diameter is. And accordingly the square on the diameter is equal to the squares on the said edges. This is also evident from the semicircle described about the sphere's diameter, in which the tetrahedron's edge is AC and the cube's edge is BC. [p] For it is clear that the diameter of the sphere AB can sustain both the straight line AC and the straight line BC, since the angle ACB is right. [Margin (p): Elements I.47]

SCHOLIVM.

If from some material six mutually equal squares are made and arranged as this figure shows, a cube is easily put together in its full solidity, provided the said squares are properly folded together; for from them there will be produced a certain solid figure containing eight solid angles, like a die of some kind, as is evident.

Diagram. The net (unfolding) of the cube: six squares (drawn in dashed outline) laid out in a cross / T-shaped pattern — a horizontal row of squares with one square above and one below — which folds up into the solid. Uncaptioned; no letter-labels.

PROBL. 4. PROPOS. 16.

[Margin: xvi.]

To construct an icosahedron and to comprehend it in a sphere (as was done for the figures already described too), and to demonstrate that the edge of the icosahedron is the irrational line called *minor*.

Let AB be the diameter of the sphere that comprehends the aforesaid figures, and about it let the semicircle ACB be described; and from AB let the fifth part BD be cut off, so that AB is quintuple BD, and sesquiquartan (5:4) to AD, while AD is quadruple BD. Then, DC having been drawn perpendicular to AB, let the straight lines AC, BC be joined. At the interval of the straight line EF, which is equal to BC, let a circle be described from the center E, [a] in which let the equilateral pentagon FGHlk be inscribed. [Margin (a): Elements IV.11] After this, the arcs FG, GH, HI, Ik, kF having been bisected at the points L, M, N, O, P, let the straight lines FL, LG, GM, MH, and so on, be joined — namely the sides of a decagon. Then from the center E and from the points L, M, N, O, P let the perpendiculars EQ, LR, MS, NT, OV, PX be erected to the plane of the circle FGHlk, set equal to the radius EF, or the straight line BC. And they will all be equal to one another; [b] but they are also parallel. [Margin (b): Elements XI.6] Therefore the straight lines joining them — namely EL, QR; EM, QS; EN, QT; EO, QV; EP, QX (all of which, however, we have not drawn, in order to avoid confusion) — [c] will be equal two by two. [Margin (c): Elements I.33] And accordingly, since EL, EM, and so on, are equal to the radius EF, the lines QR, QS, QT, QV, QX will also be equal, both to one another and to the radius EF, or the straight line BC. [d] Now since the plane drawn through the straight lines QR, QS is parallel to the plane FGHlk drawn through the straight lines EL, EM; [Margin (d): Elements XI.15] and by the same reasoning the plane drawn through the straight lines QS, QT is parallel to the same plane FGHlk drawn through the straight lines EM, EN; and the plane through the straight lines QR, QS agrees with the plane through...

[Book XIII — Proposition 16, continued: the icosahedron comprehended in a sphere]

in the straight line QS. These two planes, therefore, will make a single plane, by what we demonstrated at Proposition 16 of Book XI. In the same way we shall show that the plane through QT, QV makes a single plane with this one; and likewise the plane through QV, QX, and the plane through QX, QR. There are, then, five lines QR, QS, QT, QV, QX in one and the same plane. And accordingly, if

from Q, at the distance QR, a circle is described in that plane, it will pass through the remaining points S, T, V, X, and will be equal to the circle FGHIK.

Let the points R, S, T, V, X be joined by the straight lines RS, ST, TV, VX, XR.
[Margin: e. Elements XI.6] Now since LR, PX are equal and parallel, then — if one imagines the line LP drawn — [Margin: f. Elements I.33] LP, RX will also be equal and parallel. [Margin: g. Elements III.28 (printed "28. tertijdec." = XIII.28, but Book XIII has only 18 propositions and the content is III.28: in equal circles equal chords cut off equal arcs) [recte: III.28]] And so, in equal circles they will cut off equal arcs. But LP cuts off a fifth part of the circle FGHIK, namely the two-tenths FL, FP. Therefore RX too will cut off a fifth part of the circle RSTVX. By exactly the same reasoning we shall conclude that the remaining lines RS, ST, TV, VX cut off fifth parts. For this reason RSTVX is an equilateral pentagon, all of whose sides are equal to the sides of the pentagon FGHIK.

From the angles of the pentagon RSTVX let there be dropped, to the angles of the pentagon FGHIK, the straight lines RF, RG, SG, SH, TH, TI, VI, VK, XK, XF. Now the perpendicular LR is set equal to the radius EF — that is, to the side of the hexagon of circle FGHIK — and LF is the side of the decagon of the same circle; [Margin: h. Elements XIII.10] therefore the square on the side of the pentagon of that same circle will be equal to the squares on the lines LR, LF. [Margin: i. Elements I.47] But the square on the line FR is also equal to those same squares, since the angle FLR is right, by definition 3 of Book XI. The square on FR is therefore equal to the square on the side of the pentagon; and hence the line FR is equal to the side of the pentagon LP, or FG — that is, to RX itself. By the same reasoning the remaining lines RG, SG, SH, and so on, will be equal to the remaining sides of both pentagons.

And therefore the ten triangles RFX, RFG, RGS, SGH, SHT, THI, TIV, VIK, VKX, XKF will be equilateral and equal to one another, since all their sides are equal to the sides of the equilateral pentagon.

After this, let the perpendicular EQ be extended in both directions, and let the lines QY, EZ each be made equal to the side of the decagon of circle FGHIK (or of RSTVX); and let there be joined the lines VQ, VY, XQ, XY, GE, GZ, HE, HZ. Now QX is the radius of circle RSTVX — that is, the side of its hexagon — and QY is the side of the decagon of the same circle; [Margin: k. Elements XIII.10] therefore the square on the side of the pentagon XV will be equal to the squares on the lines QX, QY. [Margin: l. Elements I.47] But the square on the line XY is also equal to those same squares, since the angle XQY is right, by definition 3 of Book XI. (For the planes of the circles FGHIK, RSTVX have been shown to be parallel, and EQ is

at right angles to the plane of the former by construction; so EQ will also be at right angles to the plane of the latter, by the scholium to Proposition 14 of Book XI, and therefore perpendicular to the line QX, in the same plane.) Therefore the square on the line XY is equal to the square on the line XV, and consequently the line XY is equal to XV.

In the same way VY will be shown equal to that same XV; and accordingly the triangle VYX is equilateral. In no other way — if the lines RY, SY, TY are drawn (which, to avoid confusion of lines, we did not mention) — shall we demonstrate that the four triangles RYX, RYS, SYT, TYV are equilateral and equal to the triangle VYX, that is, to the previous ten, since all their sides are equal to the sides of the pentagon. By similar reasoning the triangle GZH will be equilateral (since EG is the side of the hexagon, namely the radius, and EZ the side of the decagon, and the angle GEZ is right, by definition 3 of Book XI); and likewise the four triangles HZI, IZK, KZF, FZG (whose lines, again, to avoid producing confusion, we did not draw), which will all be equal to the previous fifteen, for the same reason. Since, then, all these twenty triangles are equilateral and equal, and each is joined to each by straight lines — namely by their sides — there will be constituted out of them an icosahedron. And I say that it is comprehended by the sphere of diameter AB.

For let the line EQ be bisected at α , and let the lines αF , αX , αV be drawn. The sides αQ , QV of the triangle αQV are equal to the sides αQ , QX of the triangle αQX — because QV, QX are radii of circle RSTVX — and the angles αQV , αQX are also equal, namely right, by definition 3 of Book XI; [Margin: m. Elements I.4] therefore the bases αV , αX will also be equal. And by the same reasoning, if lines are drawn from α and Q to R, S, T, the lines αR , αS , αT will be shown equal both to one another and to αV , αX themselves. Again, the sides αQ , QX of the triangle αQX are equal to the sides αE , EF of the triangle αEF — because QX, EF are radii of equal circles, and EQ has been bisected at α ; and the angles αQX ,

Diagram. An auxiliary semicircle standing on the horizontal diameter AB, used to obtain the mean proportional. The apex C lies on the arc; from C the chords CA and CB are drawn (the angle at C being right, in a semicircle), and CD is dropped perpendicular to the diameter at D, which divides AB (tick-marks on the diameter mark the division). This realizes $AB : BC = BC : BD$.

- A (left end of diameter): terminus of AB
- D (on the diameter, marked by ticks): foot of the perpendicular from C; the point of division
- B (right end of diameter): terminus of AB

- C (apex, on the arc): vertex of the right angle

Diagram. The plane projection of the icosahedron inscribed in its circumscribing circle. Within the great circle two interlocking equilateral pentagons are shown — the upper pentagon FGHIK and the pentagon RSTVX — together with their centers, the two apex ("pole") points Y and Z, the decagon-division points L, M, N, O, P, and the full mesh of chords forming the twenty triangular faces. All labels below are read directly from the plate.

- R (upper left, on the circle): vertex of pentagon RSTVX
- X (upper center, on the circle): vertex of pentagon RSTVX
- F (upper center, inner): vertex of pentagon FGHIK
- P (upper right): decagon-division point
- L (left of F): decagon-division point
- G (left, inner): vertex of pentagon FGHIK
- E (center): center of circle FGHIK
- α (just right of E; printed as the "œ"-like alpha): midpoint of EQ / sphere-center
- Q (right of center): center of circle RSTVX
- Y (right): apex (pole) point
- K (right, on/near circle): vertex of pentagon FGHIK
- Z (lower left of center): apex (pole) point
- M (left, lower): decagon-division point
- S (far left, on the circle): vertex of pentagon RSTVX
- H (lower left, inner): vertex of pentagon FGHIK
- N (lower center): decagon-division point
- I (lower right, inner): vertex of pentagon FGHIK
- V (right, on the circle): vertex of pentagon RSTVX
- O (lower right, small): decagon-division point
- T (bottom, on the circle): vertex of pentagon RSTVX

are equal, namely right, by definition 3 of Book XI. [Margin: n. Elements I.4] The bases αX , αF will also be equal; and in the same way, if lines are drawn from α and E to G, H, I, K, the lines αG , αH , αI , αK will be shown equal to that same αX . And accordingly the ten lines drawn to the ten angles F, G, H, I, K and R, S, T, V, X are equal.

Now QE is the radius — that is, the side of the hexagon of circle FGHIK — and EZ is the side of the decagon of the same circle; [Margin: o. Elements XIII.9] therefore

the line QZ, cut at E, is in extreme and mean ratio, and its greater segment will be QE. Hence the lesser segment ZE, taking to itself αE (the half of the greater segment) — that is, the line αZ — [Margin: p. Elements XIII.3] has as its square five times the square described on αE . But the line αF too has as its square five times that same square on αE . (For the square on the line EF is four times the square on αE , since EF is double αE , by the scholium to Proposition 4 of Book II; so the squares on the lines EF and αE together are five times the square on αE . [Margin: q. Elements I.47] Since, then, the square on the line αF is equal to the squares on the lines EF, αE , the square on the line αF will also be five times the square on αE .) Therefore the squares on the lines αZ , αF are equal, and hence the lines αZ , αF themselves will be equal. Since, then, ZY is bisected at α — because equal lines EZ, QY are added to the equal lines αE , αQ , so that the wholes $Z\alpha$, $Y\alpha$ become equal — all the lines drawn from α to all the angles of the icosahedron will be equal. Wherefore a sphere described about the diameter ZY, from the center α , will pass through all the angles of the constituted icosahedron. This sphere, then, I say is equal to the sphere of diameter AB.

For as αZ is to αE , so is YZ (which is double αZ) to QE (which is double αE); [Margin: s. Elements VI.22] and accordingly, as the square on the line αZ is to the square on the line αE , so is the square on the line YZ to the square on the line QE. But the square on the line αZ has been shown to be five times the square on the line αE ; therefore the square on the line YZ will also be five times the square on the line QE — that is, five times the square on the line BC, because the line QE is set equal to the radius EF, that is, to the line BC. But the square on the line AB is also five times that same square on the line BC. (For since, by the corollary of Proposition 8 of Book VI, as AB is to BC, so is BC to BD, it follows — by the corollary of Proposition 20 of Book VI — that as AB is to BD, so is the square on the line AB to the square on the line BC; and accordingly, AB being five times BD, the square on the line AB will also be five times the square on the line BC.) Therefore the squares on the lines YZ, AB are equal, and hence also the lines YZ, AB themselves; and consequently the spheres about them will be equal. [Margin: r. Elements V.15]

Finally, the diameter AB of the sphere is assumed rational — (for it is by comparison with it that the side of the icosahedron must be shown to be an irrational line, the one called minor) — and AB has, as its square, five times the square on the line BC, that is, on EF, which is equal to that line; therefore the radius EF of circle FGHK will also be rational. (For since the squares on the lines AB, EF have to one another the ratio of a number to a number — namely of 5 to 1, or 10 to 2 — [Margin: t. Elements X.6 (printed numeral read as "8" but the content

— commensurability of magnitudes with a numerical ratio — is X.6; glyph uncertain) [?]] they will be commensurable; and consequently the lines AB, EF will also be commensurable, at least in square. Since, then, AB is rational, EF will also be rational.) Wherefore the whole diameter of circle FGHIK will be rational; and consequently the line FG, the side of the pentagon — that is, the side of the icosahedron — [Margin: u. Elements XIII.11] will be an irrational line, the one called minor. We have therefore constituted an icosahedron, and comprehended it in a sphere — the same by which we comprehended the aforesaid figures — and we have demonstrated that the side of the icosahedron is an irrational line, the one called minor; which was to be done.

COROLLARIVM. I.

From what has been said it is inferred that the diameter of the sphere is, in square, five times the radius of the circle that encloses five sides of the icosahedron — the circle, that is, out of which the icosahedron was constituted, and which passes through five angles of the icosahedron. For it has been shown that the square on the diameter AB is five times the square on the line BC, that is, on the radius EF.

Diagram. A re-impression of the same auxiliary semicircle as on the preceding page (fig-p562-1): semicircle on diameter AB, apex C, foot D dividing the diameter, chords CA, CB and perpendicular CD, giving $AB : BC = BC : BD$.

- A (left end of diameter): terminus of AB
- D (on the diameter): foot of the perpendicular; point of division
- B (right end of diameter): terminus of AB
- C (apex, on the arc): vertex of the right angle

Diagram. A re-impression of the same icosahedron projection as on the preceding page (fig-p562-2): the great circle enclosing the two interlocking pentagons FGHIK and RSTVX, with center E, second center Q, sphere-center α , apex points Y and Z, decagon points L, M, N, O, P, and the full chord mesh. Labels as on fig-p562-2 (R, X, F, P, L, G, E, α , Q, Y, K, Z, M, S, H, N, I, V, O, T).

COROLLARIVM. II.

Likewise it is manifest that the diameter of the sphere is composed of the side of the hexagon — that is, of the radius — together with two sides of the decagon of the same circle. For YZ, the diameter of the sphere, is composed of EQ, the side of the hexagon, and of QY, EZ, the sides of the decagon of circle FGHIK.

COROLLARIVM. IIL [recte: III]

Finally, it is established that opposite sides of the icosahedron — such as RX, HI — are parallel. For the line RX has been shown to be parallel to the line that would be drawn from L to P. Since, then, the line HI is also parallel to that same line LP — as we demonstrated in the scholium to Proposition 27 of Book III (because the arcs HL, IP are equal, each containing three-tenths of the whole circumference) — it is clear that the lines RX, HI are parallel. And the same reasoning holds for the other opposite sides.

SCHOLIVM.

If out of some material twenty equilateral triangles, equal to one another, are made and arranged as this figure indicates, an icosahedron will be composed in its full solidity, provided they are properly fitted together.

Diagram. The net (unfolded development) of the icosahedron: a band of twenty equal equilateral triangles, arranged in alternating rows (points up / points down) so that, folded, they form the twenty faces of the solid. No letter-labels appear on the figure.

[Margin: xvii.]

PROBL. 5. PROPOS. 17.

To construct a dodecahedron; to comprehend it in a sphere — the same by which the aforesaid figures were comprehended; and to demonstrate that the side of the dodecahedron is an irrational line, the one called apotome [apotome].

Let one base of a cube comprehended in the given sphere be the square ABCD, and let another equal square ADEF stand upon it at right angles, so that their common section is the line AD. (For all the bases of a cube stand at right angles to one another. For in what preceded, in order that the cube might be constructed, there were erected from the angles of the base EFGH four lines EI, FK, GL, HM, perpendicular to the base EFGH itself — as can easily be seen from the figure of Proposition 15 of this book. [Margin: a. Elements XI.18] Wherefore the bases of the cube drawn through them will also be at right angles to the same base EFGH.)

Accordingly, all the sides having been bisected at the points G, H, I, K, L, M, N, let these be connected by lines cutting one another at O, P, the centers of the squares — as is established from the demonstration of the eighth problem of Book IV. Let OK, PL, PN be cut in extreme and mean ratio at the points Q, R, S; and from these

let there be raised, outside the cube, perpendicular to the planes of the squares, the lines QT, RV, SX, equal to the greater segments OQ, PR, PS. Then, the lines AT, AX, DT, DV, VX having been joined, I say that ATDVX is one of the twelve equilateral and equiangular pentagons of the dodecahedron to be constructed.

That the pentagon ATDVX lies in one plane will be shown thus. Since RV, SX are at right angles to the square ADEF, [Margin: b. Elements XI.6] they will be parallel; and accordingly, since they are equal — because the greater segments PR, PS, to which they are set equal, are equal, since the cut lines PL, PN are also equal — [Margin: c. Elements I.33] the connecting lines RS, VX will also be equal and parallel. [Margin: d. Elements I.33] But AD is also parallel to that same RS, or LN, because AN, DL are parallel and equal. [Margin: e. Elements XI.9] Therefore AD, VX are also parallel; [Margin: f. Elements XI.7] and consequently the lines joining them, AX, DV, will be in the same plane with them; and therefore

Diagram. A large perspective construction figure for Proposition 17 (the dodecahedron): a cube shown with its square faces (base ABCD and the upright square ADEF, with the further face EFGH), the edge-midpoints and square-centers, and the "roof" points T, V, X raised outside the cube on perpendiculars, generating the pentagon ATDVX and its companions. Besides the Roman-letter vertices, the plate carries a set of small Greek-letter and numeral labels marking the analogous construction on the other faces (added, as Clavius says, "to avoid confusion"); the page is heavily foxed and these small marks sit near the resolution floor. Roman-letter labels read with confidence are listed first; the Greek/numeral marks are flagged. (more than two labels uncertain).

- F (top left): angle of the cube face
- M (top center): edge-midpoint
- E (top right): angle of the cube face
- X (upper, left of center): raised "roof" vertex (SX perpendicular)
- Y (upper center): [?]
- V (upper, right of center): raised "roof" vertex (RV perpendicular)
- N (left, on the mid-line): edge-midpoint
- S (mid-line): extreme-and-mean division point (on PN)
- P (mid-line, center): center of a square face
- R (mid-line): extreme-and-mean division point (on PL)
- L (mid-line, right): edge-midpoint
- A (central node, upper): angle of the cube; pentagon vertex
- Z (center left): [?] construction point

- K (center left): edge-midpoint
- Q (below K): extreme-and-mean division point (on OK)
- T (lower left): raised "roof" vertex (QT perpendicular)
- O (lower left of center): center of a square face
- D (central node): angle of the cube; pentagon vertex
- I (lower center): edge-midpoint
- B (upper right): angle of the cube
- B (bottom center): angle of the cube
- H (bottom left of B): angle of the cube
- C (bottom center-right): angle of the cube
- α (right side; "œ"-like alpha): [?] construction point
- Small Greek-letter labels (δ , π , and others) and numeral labels (2, 3, 4, 7, 8, 9) on the left and lower parts of the figure marking the parallel construction on the other faces: [numerals/letters: ? — near the resolution floor]

(Continuing the demonstration of Proposition 17 — to construct a dodecahedron comprehended in a given sphere, and to show that its edge is the irrational line called the apotome.)

and therefore the trapezium AD, VX lies in one plane. But the triangle ATD too lies in one plane. I say that it lies in the same plane as the trapezium ADVX. For from P draw PY parallel to RV, [Margin: a — *Elem.* XI.8] which will be at right angles to the square ADEF, since RV is at right angles to that same square; and join the straight lines KT, KY. Now since, because the straight line OK has been cut [in extreme and mean ratio], as OK is to OQ, so is OQ to QK; and since KP equals OK (for they are halves of the cube's edge), and PY equals OQ (since it equals RV, which was set equal to OQ, the greater segment) — it follows that as KP is to PY, so is OQ, that is, QT, equal to them, to QK. Therefore the triangles PKY and QTK have two sides proportional and are set together at one angle K, [Margin: b — *Elem.* XI.6] so that their homologous sides are parallel — namely PK and QT to one another, each being at right angles to the square ABCD, and PY and QK to one another, each being at right angles to the square ADEF. [Margin: c — *Elem.* VI.32] Hence the remaining sides KY, KT will lie in one straight line; [Margin: d — *Elem.* XI.1] and therefore the straight line TY lies in one plane, so that the plane ATD and the plane ADVX constitute a single plane, drawn through TY, AD. Consequently the pentagon ATDVX lies in one plane.

That it is equilateral will be shown thus. Since the sides AN, NS of triangle ANS equal the sides AK, KQ of triangle AKQ (for AN, AK are halves of the cube's edge, and NS, KQ are the lesser segments of equal lines cut [in extreme and mean ratio]), and the angles ANS, AKQ are right, then, if AQ be drawn, [Margin: e — *Elem.* I.4] the bases AS, AQ will be equal. Again, since the sides AS, SX of triangle ASX equal the sides AQ, QT of triangle AQT (for the lines AS, AQ have been shown equal, and SX, QT are the greater segments of equal lines cut [in extreme and mean ratio]), and the angles ASX, AQT are right — by definition 3 of Book XI — [Margin: f — *Elem.* I.4] the bases AX, AT will likewise be equal. And if DQ be drawn, we shall show by the same argument that DT equals AT; and if DR be drawn, that DV equals DT. Therefore the four sides XA, AT, TD, DV of the pentagon are equal; and we shall show the remaining side VX equal to them in this way. [Margin: g — *Elem.* XIII.4] The squares of PN, NS together are triple the square of PS, that is, of SX. But the square of AN equals the square of PN. Therefore the squares of AN, NS together are triple the square of SX. [Margin: h — *Elem.* I.47] Since, then, the square of AS equals the squares of AN, NS, the square of AS will also be triple the square of SX; and hence the squares of AS, SX together are quadruple that same square of SX. [Margin: i — *Elem.* I.47] But the square of AX equals the squares of AS, SX. Therefore the square of AX will likewise be quadruple the square of SX, that is, of PS, that is, of XY, [Margin: k — *Elem.* I.34] for PS and XY are equal. Since, then, the square of VX is also quadruple that same square of XY (because VX is double XY, by the scholium of Proposition 4 of Book II), the squares of AX, VX will be equal, and hence the lines themselves equal. Therefore, since XA, AT, TD, DV have been shown equal, the pentagon ATDVX is equilateral.

Diagram. A large planar development of the dodecahedron-on-cube construction: the cube is drawn in oblique view, and pentagonal "roofs" are raised upon its faces, with construction lines radiating from the principal vertices A (upper-left hub) and D (central hub). It is the figure that accompanies the whole demonstration of Prop. 17.

- F, M: top edge of the development
- (top-right corner label): [?]
- X, Y, V: upper band of the net
- N, S, P, R, L: horizontal row beneath X, Y, V
- A: principal left-hand hub (many lines radiate from it)
- D: principal central hub
- T, K, G, O, I: interior construction points

- B (upper right), B, H, C (lower border): cube vertices of the development
- Numerous Greek-minuscule and numeral construction points (π , σ , ρ , ϕ , ω , and the digits 2, 3, 4, 6, 7, 8, 9) are distributed across the net but cannot be resolved cell-by-cell at this resolution. [?]*

That it is also equiangular will be made clear thus. Draw the straight lines AR, AV. Since PN has been cut at S in extreme and mean ratio, and PR, equal to the greater segment PS, has been added to it, [Margin: l — *Elem.* XIII.5] NR will also be cut at P in extreme and mean ratio, and NP will be the greater segment. [Margin: m — *Elem.* XIII.4] Therefore the squares of NR, RP together are triple the square of NP, that is, of AN. But the square of RV equals the square of RP. Therefore the squares of NR, RV are triple the square of AN; and hence the squares of NR, RV, AN are quadruple that same square of AN. [Margin: n — *Elem.* I.47] But the squares of NR, AN equal the square of AR. Therefore the squares of RV, AR are also quadruple the square of AN. [Margin: o — *Elem.* I.47] Since, then, the square of AV equals the squares of AR, RV, the square of AV will also be quadruple the square of AN. But quadruple that same square of AN is the square of AD, by the scholium of Proposition 4 of Book II, since AD is double AN. Therefore the squares of AV, AD are equal, and hence the lines AV, AD equal. By a similar argument, drawing DS, DX, we shall show that DX equals DA; and therefore the three straight lines AD, AV, AX,

AV, DX are equal to one another. Since, then, the sides TA, TD of triangle TAD equal the sides DV, VX of triangle DXV, and the bases AD, DX are equal as well, [Margin: a — *Elem.* I.8] the angles ATD, DVX will also be equal. In just the same way the angle DVX will be shown equal to the angle AXV; and hence, since in the equilateral pentagon ATDVX three angles ATD, DVX, AXV are equal, [Margin: b — *Elem.* XIII.7] it will be equiangular.

Now if two other squares of the cube, $C\alpha\beta D$ and $B\gamma\delta A$, at right angles to the square ABCD, be taken in the common sections CD, AB, and if each of their sides be bisected at the points ε , θ , λ , I, μ , ξ , π , G, which are joined by straight lines cutting one another at the centres of the squares, ρ , σ ; and if OH, OK, ρI , σG be then cut in extreme and mean ratio at the points ϕ , Q, 3, 4, from which perpendiculars ϕz , QT, 37, 48 [numeral: ?] be raised to the planes of the squares toward the outer parts of the cube, equal to the greater segments ϕO , QO, 3 ρ , 46; and if the straight lines T2, 2C, C7, 7D, DT, TA, A8, 8B, Bz be joined — we shall show by the same reasoning that the pentagons T2C7D and T2B8A are equilateral and equiangular and equal to the former ATDVX, on account of the common sides TD, TA. Three pentagons have therefore now been constructed, tangent to three

edges of the cube, AD, DC, AB, and cohering to one another along the common sides TD, TA. If, then, by the same method nine other similar pentagons be built, tangent to the remaining nine edges of the cube, a dodecahedron will be constituted. And that it is comprehended by the same sphere as the cube and the preceding figures, we shall demonstrate by this device.

Let the opposite faces of the cube be conceived as cut by planes drawn through the lines that bisect the sides of the faces — namely the plane ADEF and its opposite, by planes drawn through KM, LN; and likewise the plane ABCD and its opposite, by planes drawn through GI, HK, and so on. Since, then, the cutting planes are at right angles to the said planes of the cube (because they are parallel to the bases of the cube, which are at right angles to the planes ADEF, ABCD), [Margin: c — *Elem.* XI.19] their common sections will also be at right angles to those same planes of the cube. Hence, since YP is at right angles to the plane ADEF, when produced toward Z it will be the common section of the planes drawn through KM, LN. In the same way, if from O a perpendicular ZO be erected to the plane ABCD, it will be the common section of the planes drawn through GI, HK. [Margin: d — *Elem.* XI.39] Now since the said common sections and the diameters of the cube bisect one another, let them bisect one another at Z. But the diameters of the cube bisect one another at the centre of the sphere enclosing the cube, by Corollary 1 of Proposition 15 of this book. Therefore the point Z will be the centre of the sphere described about the cube; and hence all the straight lines drawn from Z to all the angles of the cube will be equal to one another. [Margin: e — *Elem.* XI.6] That all the straight lines drawn from Z to all the angles of the dodecahedron are equal to these as well will be made clear thus, by drawing the line ZX. Since KP, OZ are parallel, because each is at right angles to the plane ABCD,

Diagram. The same dodecahedron-on-cube construction net, reprinted on the verso to accompany the continuation of the proof. The cube is shown in oblique view with pentagonal roofs on its faces; the principal hubs are A (upper-left) and D (centre), with the sphere's centre Z among the interior points.

- X, Y, V: upper band
- N, S, P, R, L: horizontal row beneath
- A: left-hand hub; D: central hub; Z: interior centre point
- K, T, G, O, I: interior construction points
- B (upper right), B, H, C (lower border): cube vertices

- Greek-minuscle and numeral construction points (π , σ , ρ , ϕ , ω ; digits 2, 3, 4, 6, 7, 8, 9) distributed over the net, not reliably legible at this resolution. [?]*

and likewise OK, ZP are parallel, because each is at right angles to the plane ADEF, PKOZ will be a parallelogram (for the two points Z must be understood as joined), and therefore PZ will equal KO, that is, NP, half the cube's edge. But PZ also equals PR. Therefore the whole ZY will equal the whole NR. [Margin: f — *Elem.* XIII.4] Hence, since the squares of NR, PR together are triple the square of NP (because NR has been cut at P in extreme and mean ratio), the squares of ZY, PY — that is, the squares of ZY, YX — will also together be triple the square of ZX. (For XY equals PS, that is, PY.) [Margin: g — *Elem.* I.47] But the square of ZX equals the squares of ZY, YX. Therefore the square of ZX will be triple the square of ZP, that is, of half the cube's edge. And since triple that same square of half the cube's edge is also the square of the radius of the sphere enclosing the cube [Margin: h — *Elem.* V.15] (for as the diameter is to the cube's edge, so is the radius to half the edge; [Margin: i — *Elem.* VI.22] and hence, as the square of the diameter is to the square of the edge, so is the square of the radius to the square of half the edge; [Margin: k — *Elem.* XIII.15] since, then, the square of the diameter is triple the square of the edge, the square of the radius will also be triple the square of half the edge) — the square of ZX is therefore equal to the square of the radius of the sphere, or of the cube; and hence ZX equals the radius. By the same reasoning the line ZV, when drawn, will equal the radius. Or indeed, since the sides ZY, YX of triangle ZYX equal the sides ZY, YV of triangle ZYV, and the contained angles are right (for since PY is perpendicular to LN, it will also be perpendicular to VX, which is parallel to it), [Margin: l — *Elem.* I.4] the bases ZX, ZV

ZX, ZV are equal. But ZA, ZD, drawn to the angles of the cube, are equal to the radius of the sphere, as was said. There are therefore now four straight lines drawn from Z, the centre of the sphere, to the four angles A, D, V, X of the pentagon, equal to the radius of the sphere. And to show that the line ZT drawn to the fifth angle T is likewise equal to the radius, let a circle ATDVX be described about the pentagon (since it is equilateral and equiangular), and from Z, the centre of the sphere, let a perpendicular $Z\omega$ be dropped onto its plane, and let the lines ωA , ωT , ωD , ωV , ωX be joined. [Margin: a — *Elem.* I.47] Now since the square of ZA equals the squares of $Z\omega$, ωA , and the square of ZX equals the squares of $Z\omega$, ωX — while the squares of ZA, ZX are equal, because the lines ZA, ZX have been shown equal — the squares of $Z\omega$, ωA will equal the squares of $Z\omega$, ωX ; and hence, the common square of $Z\omega$ being taken away, the remaining squares of ωA , ωX will be equal, and therefore the lines ωA , ωX themselves equal. Likewise the

lines ωV , ωD will be shown equal both to one another and to ωA , ωX , since the lines ZV , ZD have been shown equal to ZA , ZX . Since, then, from ω there fall upon the circumference more than two equal straight lines, [Margin: b — *Elem.* XIII.9] the point ω will be the centre of the circle; and hence ωT is equal to the others drawn from the centre, and therefore the squares of $Z\omega$, ωA will equal the squares of $Z\omega$, ωT . [Margin: c — *Elem.* I.47] Since, then, the square of ZA equals those two, and the square of ZT equals these, the squares of ZA , ZT will be equal, and therefore the lines ZA , ZT equal. Hence the sphere enclosing the cube, described from the centre Z , will comprehend the pentagon $ATDVX$ as well; and in the same way the remaining pentagons of the dodecahedron. Therefore the dodecahedron will be comprehended by the same sphere as the cube.

Finally, since as NP is to PS , so is PS to SN , [Margin: d — *Elem.* V.15] it follows that as NL , double NP , is to RS , double PS , so is RS , double PS , to the line composed of SN , RL — that is, to double SN . If, then, the cube's edge NL be cut in extreme and mean ratio, the greater segment will be SR . But NL , thus cut as a whole, is rational (for its square is commensurable with the square of the diameter of the sphere, which is set as rational, since it is a third part of it). [Margin: e — *Elem.* XIII.6] Therefore the greater segment SR — that is, the dodecahedron's edge XV , equal to it — is an irrational line, the one called the apotome. We have therefore constituted the dodecahedron and enclosed it in the same sphere by which the aforesaid figures are enclosed; and we have demonstrated that the edge of the dodecahedron is the irrational line called the apotome. Which was to be done.

Diagram. A circle (a great circle of the sphere passing through the pentagon) with the regular pentagon inscribed and its centre marked; straight lines join the centre to every vertex and the pentagon's diagonals are drawn.

COROLLARY I.

Since, then, it has been demonstrated that the line LN , cut in extreme and mean ratio, has for its greater segment the line RS — and LN was set equal to the cube's edge, and RS to the dodecahedron's edge — it is clear that, if the cube's edge be

cut in extreme and mean ratio, the greater segment is the edge of the dodecahedron described in the same sphere.

COROLLARY II.

Likewise, the cube's edge equals the straight line subtending an angle of the pentagon of the dodecahedron comprehended in the same sphere. For AD, the cube's edge, subtends the angle T of the pentagon, and it has been shown equal to the lines AV, DX, which subtend the angles X and V of the same pentagon. And since the line subtending the said angle of the pentagon, cut in extreme and mean ratio, [Margin: f — *Elem.* XIII.8] makes the edge of the pentagon its greater segment, [Margin: g — *Elem.* XIII.5] therefore the line composed of the said line subtending the pentagon's angle — that is, of the cube's edge — together with the greater segment — that is, the dodecahedron's edge — is divided in like manner, and makes the dodecahedron's edge its lesser segment and the cube's edge its greater segment. It follows that, if a straight line be cut in extreme and mean ratio such that its lesser segment is the dodecahedron's edge, the greater segment is the cube's edge in the same sphere.

COROLLARY III.

It is also established from what has been said that in the dodecahedron there are six [cross-]lines, of which two opposite ones are parallel and are bisected — and cut at right angles — by three equal straight lines that likewise bisect one another at the centre of the dodecahedron and cut at right angles. For two of the said lines are VX, T2, which are plainly parallel to the cube's edges EF, AB; and four others are found upon the remaining four faces of the cube. Of these, the ones standing upon opposite faces of the cube are parallel (since they are parallel to parallel and opposite edges of the cube), and they are cut, by what has been demonstrated, in half and at right angles by the straight lines that join the centres of opposite faces of the cube — such as the lines YZ, 9Z, and so on, which, as has been demonstrated, intersect one another at the centre Z. I say that they cut one another in half and at right angles. In half, because, since the lines PZ, OZ equal half the cube's edge, and YP, 9O equal the equal greater segments PS, OQ, the wholes YZ, 9Z will be equal; and by the same reasoning the remaining lines drawn from Z to the sections of the opposite sides will be equal. Hence all three lines are equal and bisect one another at the centre Z. And at right angles, because in the parallelogram KOZP the angle OZP is right, being opposite to the right angle OKP. Likewise the remaining straight lines joining the centres of the faces will be shown to make right angles; for all are parallel to the edges of the cube that constitute right angles, as is clear.

COROLLARY IV.

Finally, it is established that, if the line dividing opposite lines of the dodecahedron in half and at right angles, as was said, be cut in extreme and mean ratio, the greater segment is the cube's edge, and the lesser the edge of the dodecahedron comprehended in the same sphere. For since the squares of ZY, YP have been shown triple the square of PZ, ZY will be cut at P in extreme and mean ratio, and the greater segment will be PZ, by the scholium of Proposition 4 of this book. And hence, as ZY is to ZP, so is ZP to PY; [Margin: h — *Elem.* V.15] therefore, as double ZY — namely the line dividing the opposite lines of the dodecahedron in half — is to double ZP — namely the cube's edge — so is that same double of ZP to double PY, that is, to the dodecahedron's edge. Therefore the line dividing the opposite lines of the dodecahedron in half, cut in extreme and mean ratio, makes its greater segment the cube's edge, and its lesser the edge of the dodecahedron of the same sphere.

[Continuation of the Scholium to Proposition 17 — the dodecahedron.]

Diagram. An unfolded net for the dodecahedron: twelve equal, regular pentagons drawn edge to edge in the plane. One central pentagon is ringed by five others, with a further cluster of pentagons continuing to the right, arranged so that, when folded up, the twelve faces close into the solid. No vertices are lettered.

But if twelve equilateral and equiangular pentagons, all equal to one another, are made out of some material and laid out as this figure shows, then — provided they are correctly folded together — a dodecahedron will be built up as a complete solid.

PROBL. 6. PROPOS. 18.

[Margin: xviii]

To set out the sides of the five figures and to compare them with one another.

Let AB be the diameter of the sphere. Bisect it at C; cut it at D so that BD is a third part of it; and finally cut it at E so that BE is a fifth part of it. Then describe a semicircle on AB, and from C, D, and E draw the perpendiculars CF, DG, EH to its circumference; and join the straight lines AF, BF, AG, BG, AH, BH. Next, from HA cut off HI equal to the side of the decagon inscribed in the circle whose radius — that is, whose side of the hexagon — is BH; and join the straight line BI. Finally, cut BG in extreme and mean ratio at K, and let BK be the greater segment.

Diagram. The construction for the proposition. A semicircle stands on the diameter AB (A at the left end, B at the right). On the diameter, between A and B, lie the points C, D, E (in that order from A toward B). From C, D, E the perpendiculars CF, DG, EH rise to meet the circumference at F, G, H respectively (F highest, near the top; G to its right; H lower and further right). The chords AF, BF, AG, BG, AH, BH are all drawn. The point I lies on the chord AH (with HI cut off equal to the decagon's side), and the point K lies on BG (dividing it in extreme and mean ratio).

- A (left end of diameter): endpoint
- C, D, E (on the diameter, A→B): division points (C bisects; BD = one third; BE = one fifth)
- B (right end of diameter): endpoint
- F, G, H (on the circumference): feet of the perpendiculars from C, D, E
- I (on chord AH): HI = side of the decagon
- K (on BG): point of section in extreme and mean ratio

[Clavius's demonstration.] As to setting out the sides of the said figures, I say that AG is the edge of the pyramid, or tetrahedron; AF the edge of the octahedron; BG the edge of the cube; BI the edge of the icosahedron; and finally BK the edge of the dodecahedron.

For since AG is the mean proportional between BA and AD, by the corollary of Proposition 8 of Book 6, it follows from the corollary of Proposition 20 of the same book [Margin: a. Elements XIII.13] that as BA is to AD, so is the square on BA to the square on AG. But BA is one-and-a-half times AD, since AD is 2 of the parts of which BA is 3. Therefore the square on BA is likewise one-and-a-half times the square on AG. And since the diameter of the sphere is in square one-and-a-half times the edge of the tetrahedron, AG is the edge of the tetrahedron.

Again, since AF is the mean proportional between BA and AC, by the same corollary of Proposition 8 of Book 6 — and consequently, by the adduced corollary of Proposition 20 of Book 6, as BA is to AC, so is the square on BA to the square on AF — and since BA is double AC, the square on BA is double the square on AF. [Margin: b. Elements XIV.14 — recte XIII.14] Therefore, since the diameter of the sphere is in square double the edge of the octahedron, AF is the edge of the octahedron. In the same way BF too will be the edge of the octahedron.

Next, since BG is the mean proportional between AB and BD — so that, by the two aforesaid corollaries of Book 6, as AB is to BD, so is the square on AB to the square on BG — and since AB is triple BD by construction, the square on AB is triple the

square on BG. [Margin: c. Elements XIII.15] Hence, since the diameter of the sphere is in square triple the edge of the cube, BG is the edge of the cube.

Furthermore, since by the same corollaries BH is the mean proportional between AB and BE, so that as AB is to BE, so is the square on AB to the square on BH — and since by construction AB is five times BE — the square on AB is five times the square on BH. Therefore, since the diameter of the sphere is in square five times the radius of the circle enclosing the five sides of the icosahedron, by the corollary of Proposition 1 of Proposition 16 of this book, BH will be the radius, that is, the side of the hexagon of the said circle; while HI is the side of the decagon of the same circle, by construction. [Margin: d. Elements XIII.10] Therefore the side of the pentagon has as its square the squares on BH and HI together; and consequently, [Margin: e. Elements I.47] since the square on BI is equal to the squares on BH and HI, BI is the side of the pentagon of that same circle. [Margin: f. Elements XIII.16] For which reason BI is the edge of the icosahedron.

Finally, since the edge BG of the cube is cut at K in extreme and mean ratio, BK is the greater segment — the edge of the dodecahedron inscribed in the same sphere, by the corollary of Proposition 2 of Proposition 17 of this book. The sides, then, of the five regular figures inscribed in the same sphere have been set out.

[The comparison of the sides.] As for the comparison of the sides now found: since it has been demonstrated that the diameter of the sphere is, in square, one-and-a-half times the edge of the pyramid, double the edge of the octahedron, and triple the edge of the cube, it is plain that, of whatever parts the square on the diameter is 6, of such parts the square on the edge of the tetrahedron is 4, the square on the edge of the octahedron is 3, and finally the square on the edge of the cube is 2:

Figure	Square (parts)
Diameter [Diamet.]	6
Tetrahedron [Tetraed.]	4
Octahedron [Octaed.]	3
Cube [Cub.]	2

And therefore the edge of the pyramid, or tetrahedron, is in square one-and-a-third times the edge of the cube. Moreover, the edge of the octahedron is in square one-and-a-half times [the edge of the cube]. Since, then, the squares on the sides of these three figures — namely the tetrahedron, octahedron, and cube —

together with the square described on the diameter of the sphere, have among themselves the proportion which number has to number, [Margin: g. Elements X.6] the diameter of the sphere and the sides of the said figures are commensurable lines; and hence, since the diameter of the sphere is taken to be rational, the said sides will also be rational. But because the said squares do not have the proportion which a square number has to a square number, as is established from the corollary of Proposition 24 of Book 8, [Margin: h. Elements X.9] these lines — namely the diameter of the sphere, the edge of the tetrahedron, the edge of the octahedron, and the edge of the cube — will be incommensurable in length, and hence rational and commensurable in square only.

But the sides of the icosahedron and of the dodecahedron, since they are irrational lines — the former a minor, the latter an apotome, as has been demonstrated — are in no way, that is, neither in length nor in square, commensurable with the sides just mentioned. For if the sides of these latter figures were commensurable with the sides of the former, then, since the sides of the former are commensurable with the diameter of the sphere, the sides of the latter would also be commensurable with the same diameter; and consequently, the diameter being rational, those sides too would be rational. But this is absurd, for it has been shown that they are irrational.

Diagram. The same construction as on the preceding page, repeated at the head of this page. A semicircle stands on the diameter AB, with C, D, E marked on the diameter between A and B; the perpendiculars CF, DG, EH rise to F, G, H on the circumference; the chords AF, BF, AG, BG, AH, BH are drawn; I lies on AH and K on BG.

- A, B: ends of the diameter
- C, D, E: division points on the diameter
- F, G, H: feet of the perpendiculars on the circumference
- I (on AH): with HI equal to the decagon's side
- K (on BG): section in extreme and mean ratio

Nor, moreover, are the said sides of the icosahedron and dodecahedron commensurable with each other in any way whatever. For if they were believed to be commensurable in length with each other, then, since the side of the dodecahedron is an apotome, [Margin: i. Elements X.104] the side of the icosahedron too would be an apotome. Likewise, since the side of the icosahedron is a minor line, [Margin: k. Elements X.106] the side of the dodecahedron too would be a minor line. And if they were said to be commensurable in square

only, it would follow in the same way that the side of the dodecahedron is a minor line, from the fact [Margin: l. Elements XIII.16] that the side of the icosahedron is a minor. But this is absurd. For, by the scholium to Proposition 112 of Book 10, the apotome and the minor are irrational lines wholly different from each other, so that neither is the same as the other.

Therefore, although among the sides of the five regular figures thus set out the first three are commensurable both with one another and with the diameter of the sphere, and so are rational, while the two last are incommensurable both with each other and with the diameter and the remaining sides, and so are irrational — nevertheless there is discerned among all the said sides this order: the edge of the tetrahedron is greater than the edge of the octahedron; the edge of the octahedron greater than the edge of the cube; the edge of the cube greater than the edge of the icosahedron; and finally the edge of the icosahedron greater than the edge of the dodecahedron. That is, the said sides exceed one another in turn in the very order in which we constructed the aforesaid figures. This was perhaps the reason why Euclid did not construct these figures in the same order in which he defined them.

For that the edge of the tetrahedron is greater than the edge of the octahedron is plain. Since AG, the edge of the tetrahedron, subtends a greater arc than AF, the edge of the octahedron, the straight line AG will be greater than AF, by the scholium to Proposition 28 of Book 3.

In the same way we shall show that the edge of the octahedron is greater than the edge of the cube. For BF, the edge of the octahedron, subtends a greater arc than BG, the edge of the cube.

That the edge of the cube BG is greater than the edge of the icosahedron BI we shall demonstrate by this device. Since AB is set as triple BD, [Margin: m. Elements VI.20] and squares have the doubled proportion of their sides, the square on AB will be nine times the square on BD — for the ninefold proportion is the double of the triple proportion, as appears here: 1, 3, 9. And therefore, of whatever parts the square on AB is set as 9, of such parts the square on BD will be 1. But of the parts of which the square on AB is 9, the square on BG is 3, [Margin: n. Elements XIII.15] because the former is triple the latter; and consequently the squares on GD and BD together are likewise 3 of those parts, since they are equal to the square on BG. Therefore, if the square on BD — 1 of those parts — is taken away, there will remain 2 of those parts as the square on GD. Now since the square on AB is five times the square on BH, the square on BH will be less than 2 of those parts. For since 9 to 2 has a proportion less than fivefold — because 10 to

2 has the fivefold proportion — [Margin: o. Elements V.10 [?]] the number to which 9 has the fivefold proportion will be less than 2. Hence the square on GD is greater than the square on BH, and therefore the straight line GD is greater than the straight line BH.

Now GD is composed of BH, the radius of the circle from which the icosahedron is constituted, and of the line HI, double the side of the decagon of the same circle — by the corollary of Proposition 2 of Proposition 16 of this book — for it is established that the side of the decagon [is HI, and that HI] is less than the straight line BD. For if HI were believed equal to a third part of the straight line AB, then its double would be equal to two-thirds, namely to AD; and consequently BH would be equal to the remaining third part, namely to BD. And so, since the square on AB has been shown to be nine times the square on BD, the same square on AB would be nine times the square on BH. But this is absurd, for it has been demonstrated to be five times it. Therefore HI is not a third part of AB. Nor yet is it greater than a third part. For if HI were said to be greater than a third part of AB, and consequently its double greater than two-thirds — that is, than AD — then BH would be less than a third part of BD. Hence the square on AB would be greater than nine times the square on BH; which is even more absurd. Therefore HI is not greater than a third part of AB; nor is it equal to a third part, as we have shown. It is therefore less than a third part, that is, less than BD. And so, since the straight lines GD and DB are greater than the straight lines BH and HI, as has been demonstrated, the squares on the former will also be greater than the squares on the latter. [Margin: p. Elements I.47] But the square on BG is equal to the squares on GD and DB, and the square on BI is equal to the squares on BH and HI. Therefore the square on BG is also greater than the square on BI; and consequently the straight line BG, namely the edge of the cube, is greater than the straight line BI, that is, the edge of the icosahedron.

Finally, that the edge of the icosahedron BI is greater than the edge of the dodecahedron BK will become clear by this reasoning. Since, the straight line BG being divided in extreme and mean ratio, BK is the greater segment and GK the less, the rectangle contained by BG and BK is greater than the rectangle contained by BG and GK; and so the rectangles under BG, BK and under BG, GK together are greater than twice the rectangle under BG, GK. [Margin: q. Elements II.2] But the square on BG is equal to the rectangles under BG, BK and under BG, GK; and the square on BK is equal to two rectangles under BG, GK — for since as BG is to BK, so is BK to GK, [Margin: r. Elements VI.17] the square on BK is equal to the rectangle under BG, GK, and therefore two squares on BK are equal to two rectangles under BG, GK. Therefore the square on BG is also greater than two

squares on BK; and accordingly three squares on BG will be greater than six squares on BK. But three squares on BG are equal to three squares on BH — for since the square on AB is triple the square on BG and five times the square on BH, both the three squares on BG and the five squares on BH are equal to the same square on AB, and therefore those three are equal to these five. Therefore the five squares on BH will also be greater than the six squares on BK; and consequently one square on BH will be greater than one square on BK. For if the square on BH were equal to the square on BK, or less, then five squares on BH would be less than six squares on BK — which is absurd, since those five have been shown to be greater than these six. For which reason the straight line BH too will be greater than the straight line BK; and therefore, since BI is greater than BH, BI — namely the edge of the icosahedron — will be much greater than BK, the edge of the dodecahedron. We have therefore set out the sides of the five figures and compared them with one another. Which was to be done.

SCHOLIVM.

The commentators at this point prove that, besides the said five figures, no other solid figure can be constructed that is contained by plane figures which are equilateral, equiangular, and equal to one another. Their reasoning is roughly as follows.

Out of two triangles, or out of two other figures, a solid angle cannot be constructed, since at least three plane angles are required for the construction of a solid angle.

Out of three equilateral triangles the angle of the pyramid is composed;

out of four, the angle of the octahedron;

out of five, the angle of the icosahedron.

But out of six such triangles meeting at the same point a solid angle cannot be made. For since the angle of an equilateral triangle contains two-thirds of one right angle, by the corollary of Proposition 3 of Proposition 32 of Book 1, six such angles will be twelve thirds of one right angle — that is, they will be equal to four right angles. Hence out of them no solid angle will be constructed. [Margin: 20. undecimi — Elements XI.21 [?]] For every solid angle is contained by angles less than four right angles. Much less, then, will a solid angle be made out of more than six such plane angles.

Next, out of three squares the angle of the cube is made. But out of four squares no solid angle can be constructed, for again there will be four right angles. Much less, then, will a solid angle be made out of more than four such angles.

Finally, out of three equilateral and equiangular pentagons the angle of the dodecahedron is composed. For since the five angles of a pentagon are equal to six right angles, as we showed at Proposition 32 of Book 1, and consequently one angle contains one right angle plus a fifth part of one right angle, three such angles will contain three right angles and, in addition, three-fifths of one right angle. They will therefore be less than four right angles, and so out of them a solid angle will be constructed. But out of four such angles no solid angle can be made; for since one of them, as has been said, is greater than a right angle — because it contains one right angle and, in addition, a fifth part of a right angle — four of them will be greater than four right angles. Hence no solid angle will be constructed out of them; and therefore much less can a solid angle be constructed out of more than four such angles. Nor indeed can a solid angle be constructed out of any other equilateral and equiangular figures. For since the six angles of a hexagon are equal to eight right angles, as was demonstrated at Proposition 32 of Book 1 — and consequently one angle contains one right angle plus two-sixth parts of one right angle — three such angles will contain three right angles and six sixth-parts, that is, four right angles. Hence out of them a solid angle can in no way be composed; and therefore much less will a solid angle be made out of more than three, nor for that reason out of any other polygons. For any three of them are greater than four right angles. For which reason it is plain that, besides the said five figures, no other solid figure can be constructed that is contained by plane figures equilateral, equiangular, and equal to one another.

For if three equilateral and equal triangles meet at one point to make up a solid angle, there will be constructed a pyramid contained by four such triangles.

But if four such triangles come together to compose a solid angle, an octahedron will be made, comprehended by eight such triangles.

If, finally, five such triangles are taken to form a solid angle, an icosahedron will be made, contained by twenty such triangles.

But if three equal squares meet at one point so as to constitute a solid angle, a cube will be built up out of six such squares.

Lastly, if three equilateral and equiangular pentagons, equal to one another, come together to make up a solid angle, a dodecahedron will be composed, containing twelve such pentagons.

It is also fitting to add here a certain method, taken from Hypsicles of Alexandria, by which the number of the sides and angles of any regular figure may readily be had.

[The method of Hypsicles.] If anyone asks how many edges any of the regular solids has: all its faces are to be multiplied by the number of sides of one face, so that the sides of all the faces are obtained. But since two sides of the faces always come together to make up one edge of the regular solid, half of all the sides is to be taken, so that the number of edges of the regular solid appears.

Example. If the four triangles of the pyramid, or tetrahedron, are multiplied by the number of sides of one triangle — as by 3 — they make 12, of which the half is 6, namely the number of edges of the pyramid. And likewise for the rest. For if the six squares composing the cube are multiplied by the sides of one square — namely by 4 — they make 24, of which the half is 12, namely the number of edges of the cube. And if the eight triangles of the octahedron are multiplied by 3, the number of sides of one triangle, they make 24, of which the half is again 12, the number of edges of the octahedron. If again the 20 triangles of the icosahedron are multiplied by 3, the number of sides of one triangle, they make 60, of which the half is 30, the number of edges of the icosahedron. If, finally, the 12 pentagons constituting the dodecahedron are multiplied by 5, the number of sides of one pentagon, they make 60, of which the half is again 30, the number of edges of the dodecahedron.

But if anyone should further ask how many solid angles any of the regular solids has: all its faces are to be multiplied by the angles of one face, so that the angles of all the faces are obtained. But since three, four, or five angles of the faces always come together to make up one solid angle, all the angles are to be divided by the number of angles that meet together to constitute a solid angle, so that the number of solid angles of the regular solid appears.

Example. If the four triangles of the pyramid are multiplied by 3, the number of angles of one triangle, they make 12 angles, which, if divided by 3 (for that many angles constitute one solid angle of the pyramid), yield 4 solid angles of the pyramid. If instead the 6 squares of the cube are multiplied by 4, the number of angles of one square, they make 24 angles, which, divided by 3 (for that many angles make up one solid angle of the cube), yield 8 solid angles of the cube. If also the eight triangles of the octahedron are multiplied by 3, the number of angles of one triangle, they make 24 angles, which, divided by 4 (for that many angles compose a solid angle of the octahedron), yield 6 solid angles of the octahedron. If again the 20 triangles of the icosahedron are multiplied by 3, the

number of angles of one triangle, they make 60 angles, which, divided by 5 (for that many angles constitute a solid angle of the icosahedron), produce 12 solid angles of the icosahedron. If, finally, the 12 pentagons of the dodecahedron are multiplied by 5, the number of angles of one pentagon, they make 60 angles, which, divided by 3 (for that many angles come together to constitute a solid angle of the dodecahedron), yield 20 solid angles of the dodecahedron.

Finally, it is also worth considering that the cube and the octahedron are reciprocal with respect to their faces and their solid angles. For as many faces as are contained in the one, so many solid angles are found in the other, and conversely. Thus the cube has six faces and eight solid angles, while the octahedron contains eight faces and six solid angles. In the same way the icosahedron and the dodecahedron are reciprocal. For the icosahedron has twenty faces and twelve solid angles, while the dodecahedron possesses twelve faces and twenty solid angles. The tetrahedron alone (that is, the pyramid) is reciprocal with none but itself; for it has four faces and just as many solid angles.

FINIS ELEMENTI TERTIIDECIMI.

EUCLID'S FOURTEENTH ELEMENT

And the fourth of the Solids — as some think; but, as others hold, the work of **Hypsicles of Alexandria on the five bodies.**

BOOK ONE

PREFACE of Hypsicles of Alexandria to Protarchus

Basilides of Tyre, Protarchus, having come to Alexandria and been commended to my father for their shared devotion to the discipline, spent a very long stretch of his travels in his company. On one occasion the two of them were discussing the treatment that Apollonius [of Perga] had written on the comparison of the dodecahedron and the icosahedron inscribed in the same sphere — what ratio these bear to one another — and they concluded that Apollonius had not set the matter out correctly. And so, as my father used to say, they published in writing the corrected account that they had worked out for themselves. Later, however, I came upon another book issued by Apollonius, which contained an accurate demonstration of the question proposed; and from investigating its problem I took great pleasure indeed. What Apollonius wrote can certainly be examined by everyone, since it is in everyone's hands. But what we ourselves seem to have

written afterward — with as much careful study as one may conjecture — this I have thought fit to set down in a memoir and dedicate to you, so that you, who are happily versed in all the disciplines and above all in geometry, may judge skillfully and prudently the things we are about to say. And for the sake of the intimacy of life you shared with my father, and the goodwill with which you embrace us, may you gladly give the treatment itself a hearing. But it is now time to put an end to the preface and take up what has been proposed.

[Clavius's introduction to the book.]

Thirteen books, expounded up to this point, are ascribed by everyone to Euclid; but the two that follow are commonly — and rightly, in my judgment — attributed by most to Hypsicles of Alexandria. In the earlier of the two, the icosahedron and the dodecahedron are compared with one another, both with respect to their surfaces and to their solidity; in the later, several descriptions are set out of one regular figure inside another — so that these two books are, as it were, a kind of appendix to Euclid's *Elements*. But since Hypsicles omits a great deal that is not unpleasant to know concerning the comparisons of the said five regular bodies and their mutual inscription of one within another — for this fourteenth book is completed in just four propositions, and the fifteenth in five problems — it seemed good, in order to bring some light to this treatment, to discuss the said regular figures somewhat more fully in general, proposing various theorems and problems by which the aforesaid regular bodies are both compared with one another and inscribed within one another. In this matter we do not deny that Campanus and François de Foix, Count of Candale [Franciscus Flussas Candalla], were of the greatest help to us, for he bestowed diligent and careful labor on this business. He not only enriched the two following books with a great many theorems and problems, but also added a whole book, sixteenth in order, in which he sets out notable properties of the said bodies. Moreover, that Hypsicles's chief aim in this fourteenth book was to discuss the mutual comparison of the icosahedron and the dodecahedron can readily be understood from his preface to Protarchus, set out above.

Now since in these two books Hypsicles and Campanus differ, both in the number of the propositions and in their order — differing both from one another and from François de Foix, and consequently from us as well — we have noted the order of each in the margin by two numbers: the upper indicates Hypsicles's order, the lower Campanus's series. When only a single number appears repeated in the margin, it signifies that there is then no difference between Campanus and Hypsicles. But if at any point the mark **O** is placed in the position of the upper

number, it is to be understood that the said proposition is missing in Hypsicles; and understand the same for Campanus if that mark should happen to be placed in the position of the lower number. Finally, when nothing at all is found in the margin, it is a sign that the proposition is absent from both Hypsicles and Campanus.

THEOR. 1. PROPOS. 1.

[Margin: i.]

The perpendicular drawn from the center of any circle to the side of a pentagon inscribed in that same circle is half of both lines together — namely of the side of the hexagon and the side of the decagon inscribed in the same circle.

[Demonstration.] From the center A of circle BCD let AE be drawn perpendicular to BC, the side of a pentagon described in the said circle. I say that AE is half of the line compounded of the side of the hexagon and the side of the decagon of the same circle. For let AE be extended in both directions so as to complete the whole diameter DF, and let EG be taken equal to EF; and let the straight lines AC, CG, CF, BF be joined. [Margin: a. Elem. III.3] Since, then, the perpendicular AE cuts the straight line BC into two equal parts, the sides BE, EF of triangle BEF will be equal to the sides CE, EF of triangle CEF. And since the contained angles are also equal — namely right angles — [Margin: b. Elem. I.4] the bases CF, BF will be equal; [Margin: c. Elem. III.28] and therefore the arcs CF, BF will be equal as well. Accordingly, since the arc BC is a fifth part of the whole circumference, CF will be a tenth part of it; and so the straight line CF will be the side of the decagon.

Again, since the sides CE, EF of triangle CEF are equal to the sides CE, EG of triangle CEG, and the contained angles are right angles, [Margin: d. Elem. I.4] the bases CF, CG and the angles CFG, CGF will also be equal. And since the arc CF is a fifth part of the semicircumference — being a tenth part of the whole circumference — the arc CF will be 1 such part, while the arc DC is 4 such parts; that is, the arc DC will be four times the arc CF. [Margin: e. Elem. VI.33] Hence the angle DAC will also be four times the angle CAF. [Margin: f. Elem. III.20] But the angle CFD is half the angle DAC, since the one stands at the circumference and the other at the center on the same base DC. Therefore the angle CFD — and consequently CGF, which was shown equal to it — will be double the angle CAF. [Margin: g. Elem. I.32] But the angle CGF, being exterior, equals the interior angles GAC, GCA in triangle GAC. Since, then, GAC is half of the angle CGF, as was shown, GCA will be the remaining half of that same angle CGF; and so the angles

GAC, GCA will be equal, [Margin: h. Elem. I.6] and consequently the sides AG, CG equal as well. But CG was shown equal to the straight line CF; therefore AG too will equal that same CF. Hence, adding the equal segments GE, EF, AE becomes equal to the two EF, FC together; and accordingly the three together AE, EF, FC — that is, the two together AF, FC — will be double AE. Therefore, conversely, AE — namely the perpendicular drawn to the side of the pentagon — will be half of the two AF, FC together, that is, of the side of the hexagon and the side of the decagon. Therefore the perpendicular drawn from the center of any circle to the side of a pentagon inscribed in that same circle, etc. Which was to be demonstrated.

Diagram. A circle with center A. The perpendicular from the center rises through the chord BC to the top of the circle; a vertical diameter runs through the figure.

- A (center of circle): the center from which the perpendicular is drawn
- B (upper-left, on circle): left endpoint of the chord BC (side of the pentagon)
- C (upper-right, on circle): right endpoint of the chord BC
- D (bottom, on circle): lower end of the vertical diameter DF
- F (top, on circle): upper end of the vertical diameter DF
- E (on chord BC): foot of the perpendicular AE, bisecting BC
- G (on the vertical between E and A): point taken so that EG = EF

Lines drawn: chord BC; diameter DF (through center A); and the straight lines AC, CG, CF, BF.

COROLLARY I.

From this it follows that a perpendicular drawn from the center of a circle to a straight line fitted within the same circle bisects the arc which that straight line subtends. For it has been demonstrated that the straight line AE, which is perpendicular from the center to BC, divides the arc BC into two equal parts at F.

COROLLARY II.

Hence it also follows that the perpendicular drawn from the center to the side of the pentagon equals both lines together — namely the perpendicular drawn from the center to the side of the equilateral triangle inscribed in the same circle, together with half the side of the decagon. For, as was shown in this proposition, the perpendicular to the side of the pentagon equals half the side of the hexagon and half the side of the decagon together; and the perpendicular to the side of the equilateral triangle, by the corollary of Prop. 12 of Book XIII, equals half the

radius — that is, half the side of the hexagon. It is therefore clear that this same perpendicular to the side of the pentagon equals the perpendicular to the side of the triangle together with half the side of the decagon.

THEOR. 2. PROPOS. 2.

[Margin: iv. / ij.]

If two straight lines are each cut in extreme and mean ratio, they will be cut similarly — that is, into the same proportions.

[Demonstration.] Let the two straight lines AB and CD be cut in extreme and mean ratio at E and F. I say that they are cut into the same proportions — that is, that as AB is to CD, so is AE to CF and EB to FD; and likewise, as AE is to EB, so is CF to FD, and so on. For since AB is to AE as AE is to EB, and CD is to CF as CF is to FD, [Margin: a. Elem. VI.17] the rectangle contained by AB, EB equals the square on AE, and the rectangle contained by CD, FD equals the square on CF. For this reason, as the rectangle under AB, EB is to the square on AE, so is the rectangle under CD, FD to the square on CF (for in both cases it is a ratio of equality). And therefore, by what we demonstrated in the scholium to Prop. 22 of Book V, as four times the rectangle under AB, EB is to the square on AE, so four times the rectangle under CD, FD is to the square on CF; and, compounding, as four times the rectangle under AB, EB together with the square on AE is to the square on AE, so four times the rectangle under CD, FD together with the square on CF is to the square on CF.

[Margin: b. Elem. II.8] But four times the rectangle under AB, EB together with the square on AE equals the square on the line compounded of AB, EB; and four times the rectangle under CD, FD together with the square on CF equals the square on the line compounded of CD, FD. Therefore also, as the square on the line compounded of AB, EB is to the square on AE, so is the square on the line compounded of CD, FD to the square on CF; [Margin: c. Elem. II.2] and accordingly, as the line compounded of AB, EB is to AE, so is the line compounded of CD, FD to CF. And, compounding, as the compound line of AB, EB together with AE — that is, twice AB — is to AE, so is the compound line of CD, FD together with CF — that is, twice CD — to CF. And, alternating, as twice AB is to twice CD, so is AE to CF. [Margin: d. Elem. V.15] But as twice AB is to twice CD, so is AB to CD. Therefore, as AB is to CD, so is AE to CF. And since, as the whole AB is to the whole CD, so is AE (removed) to CF (removed), [Margin: e. Elem. V.19] the remainder EB will also be to the remainder FD as whole to whole. Hence, as AE is to CF, so will EB be to FD, since each ratio is the same as the ratio of AB to CD. And, alternating,

as AE is to EB, so will CF be to FD. And so, finally, by all the modes of arguing from proportionality, we shall show that both the whole lines and their parts are proportional to one another. Therefore, if two straight lines are cut in extreme and mean ratio, etc. Which was to be demonstrated.

- Lower segment: C (left end) — F (division point) — D (right end)

SCHOLIUM.

Here we shall easily demonstrate the following theorem.

The side of the hexagon has the same ratio to the side of the decagon described in the same circle as the straight line subtending an angle of an equilateral and equiangular pentagon has to the side of that pentagon.

[Demonstration.] For since [Margin: f. Elem. XIII.9] the side of the hexagon together with the side of the decagon makes a line cut in mean and extreme ratio, and [Margin: g. Elem. XIII.8] the straight line subtending an angle of the pentagon, when cut in extreme and mean ratio, has for its greater segment the side of the pentagon itself, [Margin: h. Elem. XIV.2] it comes about that the ratio of the side of the hexagon to the side of the decagon — that of the greater segment to the greater — is the same as the ratio which the greater segment of the straight line subtending the pentagon's angle has to the lesser. Since, then, as the greater segment is to the lesser, so is the whole to the greater segment, the side of the hexagon will also be to the side of the decagon as the straight line subtending an angle of the equilateral and equiangular pentagon is to the side of that pentagon. Which is what was proposed.

From this proposition, together with the preceding one, we shall also infer this further theorem.

If the perpendicular drawn from the center of a circle to the side of a pentagon described in the same circle is cut in extreme and mean ratio, the greater segment equals the perpendicular drawn from the same center to the side of the equilateral triangle, while the lesser segment equals half the side of the decagon inscribed in the same circle.

[Demonstration.] For from the center A of circle BC let the perpendicular AD be drawn to BC, the side of a pentagon inscribed in the same circle, and let it be cut at E in extreme and mean ratio. I say that the greater segment AE equals the perpendicular drawn from A to the side of the equilateral triangle of the same circle, while the lesser segment ED equals half the side of the decagon of the same circle. For let the straight line AD be extended to F, and let the straight line FC be joined; then FC will be the side of the decagon, since — by Corollary 1 of Prop. 1 of this book — the arc BC (namely a fifth part of the whole circumference) is bisected at F. [Margin: i. Elem. XIII.9] And accordingly the line compounded of AF (the side of the hexagon) and FC (the side of the decagon) is cut in extreme and mean ratio, its greater segment being AF, the side of the hexagon, and its lesser segment FC, the side of the decagon. Therefore, as was shown in this proposition, as the whole AD, divided according to extreme and mean ratio, is to the whole compounded of AF, FC, similarly divided, so is AE (the greater segment) to AF (the greater segment), and ED (the lesser segment) to FC (the lesser segment). [Margin: k. Elem. XIV.1] But the whole AD is half of the whole compounded of AF, FC. Therefore AE will be half of AF (the radius), and ED half of FC (the side of the decagon). Since, then, by the corollary of Prop. 12 of Book XIII, the perpendicular drawn from the center to the side of the equilateral triangle equals half the radius, it is clear that the greater segment AE equals the said perpendicular, while the lesser segment ED equals half the side of the decagon. Which is what was proposed.

Diagram. A circle with center A near the lower middle; a short chord BC near the top, with the perpendicular from the center rising through it to the circumference.

- A (lower center, center of circle): center from which the perpendicular AD is drawn
- B (upper-left, on circle): left endpoint of the chord BC (side of the pentagon)
- C (upper-right, on circle): right endpoint of the chord BC
- D (on chord BC): foot of the perpendicular AD
- F (top, on circle): point where AD, extended, meets the circle (bisecting arc BC)

- E (on AD, between D and A): point cutting AD in extreme and mean ratio

Lines drawn: chord BC; the perpendicular AD extended to F; and the straight line FC.

PROBL. 3. PROPOS. 3.

[Margin: ij. / iv.]

If an equilateral pentagon is described in a circle, then the square on the side of the pentagon and the square on the line that subtends two sides of the pentagon, both together, are five times the square described on the radius.

[Demonstration.] In the circle ABCDE, whose center is F, let a pentagon ABCDE be described, and let the straight line AC subtend the two sides AB, BC. I say that the squares on the straight lines CD, AC together are five times the square on the radius of the described circle. For let the straight line AFG be drawn from A through the center; by Corollary 2 of Prop. 10 of Book XIII it bisects both the arc CD and the side CD — at G and H respectively. Then the arc CG will be a tenth part of the whole circumference, and so the straight line CG subtending it will be the side of the decagon. Now since the straight line AG is double the straight line FG, by the scholium to Prop. 4 of Book II the square on AG will be four times the square on FG. [Margin: a. Elem. I.47] But the squares on the straight lines AC, CG together equal the square on AG. Therefore the squares on the straight lines AC, CG together are also four times the square on the [side FG] ...

Diagram. A circle with an inscribed equilateral pentagon ABCDE and center F; a vertical diameter runs from the top vertex A down through the center to the bottom of the circle, with diagonals drawn.

- A (top vertex, on circle): apex of the pentagon; upper end of the diameter AFG
- B (upper-left vertex, on circle)
- C (lower-left vertex, on circle)
- D (lower-right vertex, on circle)
- E (upper-right vertex, on circle)
- F (center of circle)
- G (bottom, on circle): lower end of the diameter AFG (bisecting arc CD)
- H (on the chord CD): point where AG meets and bisects CD

Lines drawn: the pentagon ABCDE; the diagonal AC (subtending sides AB, BC); the diameter AFG; and the chords CG and CD.

Book XIV (Hypsicles) — continued

Proposition 3 (continued) — Demonstration

[to] FG. And so the three squares on the lines AC, CG, and FG are five times the square on that same line FG. [Margin: b — *Elements* XIII.10] Since, therefore, the squares on the lines FG and CG — that is, on the side of the hexagon and on the side of the decagon — together equal the square on the line CD, namely on the side of the pentagon, the squares on the lines AC and CD will likewise be five times the square on the line FG, that is, on the radius. If, then, an equilateral pentagon is inscribed in a circle, the square on the side of the pentagon together with the square on the line that subtends two sides of the pentagon are, taken together, five times the square described on the radius. This was to be demonstrated.

Diagram. A circle with center F, in which the equilateral pentagon ABCDE is inscribed. The diameter AFG runs vertically from A (top) through the center F to G (bottom); it bisects the pentagon's base CD at the point H. The diagonal AC is drawn, together with the chords CG and CD.

- A (top of circle): pentagon vertex; upper end of the diameter
- B (upper left): pentagon vertex
- C (lower left): pentagon vertex
- D (lower right): pentagon vertex
- E (upper right): pentagon vertex
- F (center): center of the circle
- G (bottom): lower end of the diameter, diametrically opposite A
- H (on CD, below F): point where the diameter AG meets and bisects the base CD

Corollary

There follows from these results a theorem of this kind.

If a cube and a dodecahedron are inscribed in the same sphere, the square on the side of the cube and the square on the side of the dodecahedron, taken together, are five times the square on the radius of the circle that circumscribes a pentagon of the dodecahedron.

For let the circle ABCDE circumscribe one pentagon of a dodecahedron inscribed in some sphere. Then, by the second corollary to Proposition 17 of Book 13, the line AC, which subtends the pentagon's angle B, will be the side of the cube inscribed in the same sphere. [Margin: c — *Elements* XIV.3] And it is clear that the squares on the lines AC and CD — that is, on the side of the cube and on the side of the dodecahedron — are five times the square on the radius FG, and so on.

THEOR. 4. PROPOS. 4.

[Margin: outer dual proposition numbers "[?]. / iij." — Hypsicles-upper / Campanus-lower; foxed]

If the side of the hexagon of some circle is cut in extreme and mean ratio, its greater segment will be the side of the decagon of the same circle.

Demonstration. For let AB, the side of the hexagon of some circle, be cut in extreme and mean ratio at C, and let AC be the greater segment. I say that AC is the side of the decagon of the same circle. Let AD be the side of the decagon of the same circle, and let it be joined in a straight line to AB. [Margin: a — *Elements* XIII.9] Then the whole line BD, composed of the side of the hexagon and the side of the decagon, will have been divided at A in extreme and mean ratio, its greater segment being BA. But AB too has been cut at C in the same way. [Margin: b — *Elements* XIV.2] Therefore, as BD, the whole, is to its greater segment AB, so is AB, the whole, to its greater segment AC. But it is also the case that, as BD, the whole, is to its greater segment AB, so is AB, the greater segment, to AD, the lesser segment, by the definition of a line cut in extreme and mean ratio. Therefore, as AB is to AC, so is the same AB to AD; and consequently AC and AD are equal. Since, then, AD is taken to be the side of the decagon of that circle whose side of the hexagon is AB, AC too will be the side of the decagon of the same circle.

Alternatively. Let there be joined to AB, in a straight line, the line AD equal to the greater segment AC. [Margin: c — *Elements* XIII.5] Then the whole line BD will have been divided at A in extreme and mean ratio. Since, therefore, AB, its greater segment, is taken to be the side of the hexagon of some circle, then — by what we demonstrated at Proposition 9 of Book 13 — AD, the lesser segment, will be the side of the decagon of the same circle; and consequently AC too, being equal to AD, will be the side of the decagon inscribed in the same circle whose side of the hexagon is taken to be AB. If, then, the side of the hexagon of some circle, and so on. This was to be shown.

Diagram. A single straight line marked, from left to right, with the points B, C, A, D. AB is the side of the hexagon (cut at C in extreme and mean ratio, greater segment AC); AD, joined on in a straight line, is the side of the decagon.

- B (left end): endpoint of the hexagon side
- C (between B and A): point of section in extreme and mean ratio
- A (between C and D): common point where the hexagon side AB meets the decagon side AD
- D (right end): outer endpoint of the decagon side

THEOR. 5. PROPOS. 5.

[Margin: outer dual proposition numbers "ij. / v."]

The same circle circumscribes both a pentagon of the dodecahedron and a triangle of the icosahedron inscribed in the same sphere.

Demonstration. In a sphere whose diameter is A, let there be understood to be described both a dodecahedron, one of whose pentagons is BCDEF, and an icosahedron, one of whose triangles is GHI. I say that the same circle circumscribes both the pentagon BCDEF and the triangle GHI — that is, that the circles BCDEF and GHI, which circumscribe them, are equal. For let the circle KLMNO circumscribe the pentagon KLMNO [Margin: a — *Elements* XIII.13] from which the icosahedron is inscribed in the sphere, in such a way that the five sides of this pentagon are sides of the icosahedron, and therefore each of them is equal to a side of the triangle GHI. Next, from the centers P, Q, R let the lines PE, QH, RM be drawn; and let RM be cut in extreme and mean ratio at S. [Margin: b — *Elements* XIV.4] Then the greater segment RS will be the side of the decagon in the circle KLMNO, in which RM is the side of the hexagon. Let the line CF also subtend the angle B of the pentagon of the dodecahedron; by the second corollary to Proposition 17 of Book 13, this will be the side of the cube described in the same sphere. Since, therefore, by the first corollary to the same Proposition, BF, the side of the dodecahedron, is the greater segment of the side of the cube CF cut in extreme and mean ratio, [Margin: c — *Elements* XIV.2] it will follow that, as the whole CF is to the whole RM, so is BF, the greater segment, to RS, the greater segment; and consequently, as the square on the line CF is to the square on the line RM, so is the square on the line BF to the square on the line RS. And so, by Proposition 22 of Book 5, as three times the square on the line CF is to five times the square on the line...

[The three-circle figure for this proposition is printed here at the foot of the page; it is reproduced again at the head of the following page. See fig-p574-3 below.]

Diagram. Three circles. At the very top a separate short straight segment is marked A — the diameter of the sphere. **Upper-left circle:** the pentagon BCDEF inscribed, with center P; B is at the top, C at the upper left, F at the upper right, D at the lower left, E at the lower right; the line PE is drawn from the center to E. **Upper-right circle:** the triangle GHI inscribed, with center Q; G is at the top, H at the lower left, I at the lower right; the line QH is drawn from the center to H. **Lower circle:** the pentagon KLMNO inscribed, with center R; K is at the top, L at the upper left, O at the upper right, M at the lower left, N at the lower right; the line RM is drawn from the center to M and is cut at S (between R and M).

- A (top segment): the sphere's diameter, shown apart
- B, C, D, E, F: vertices of the dodecahedron's pentagon (upper-left circle); P its center; PE drawn
- G, H, I: vertices of the icosahedron's triangle (upper-right circle); Q its center; QH drawn
- K, L, M, N, O: vertices of the pentagon circumscribing the icosahedron (lower circle); R its center; RM drawn and cut at S

[The three-circle figure of Proposition 5 (fig-p574-3) is reprinted here in the outer part of the page, alongside the continuing demonstration.]

Proposition 5 — Demonstration (continued)

on the line RM, so is three times the square on the line BF to five times the square on the line CF, [and this is] equal to five times the square on the line RM — because both three times the square on the side of the cube CF (by Proposition 15 of Book 13) and five times the square on the radius RM (by the first corollary to Proposition 16 of Book 13) are equal to the square on A, the diameter of the sphere. Therefore three times the square on the line BF too will be equal to five times the square on the line RS. [Margin: e — *Elements* XIII.10] Now since the square on the line MN, the side of the pentagon, is equal to the square on the side RM of the hexagon together with the square on the line RS, the side of the decagon, five squares on the line MN will likewise equal five squares on the line RM together with five squares on the line RS. Therefore five squares on the line MN are also equal to three squares on the line CF (since these have been shown to be equal to five squares on the line RM) together with three squares on the line BF (which were equal to five squares on the line RS). But since [Margin: f — *Elements* XIV.3] the squares on the lines CF and BF are together equal to five

squares on the radius PE, three squares on the line CF together with three squares on the line BF are equal to fifteen squares on the line PE; and five squares on the line MN are equal to fifteen squares on the radius QH. [Margin: g — *Elements* XIII.12] (For since MN has been shown to be equal to GH, the side of the icosahedron, that is, of the equilateral triangle, and since the square on that GH is equal to three squares on the radius QH, five squares on the line GH — that is, on the line MN — will be equal to fifteen squares on the line QH.) Fifteen squares on the line PE will therefore also be equal to fifteen squares on the line QH; and consequently one square on the line PE is equal to one square on the line QH, and therefore the radius PE is equal to the radius QH. The circles BCDEF and GHI are therefore equal. The same circle, then, circumscribes both, and so on. This was to be demonstrated.

THEOR. 6. PROPOS. 6.

[Margin: outer dual proposition numbers "iij. / vi."]

If, from the center of the circle circumscribing a pentagon of the dodecahedron, a perpendicular is drawn to one side of the pentagon, then the rectangle contained by the said side and the perpendicular, taken thirty times, will be equal to the surface of the dodecahedron.

Demonstration. From F, the center of the circle circumscribing the pentagon ABCDE of the dodecahedron, let the perpendicular FG be drawn to the side CD. I say that the rectangle under FG and CD, taken thirty times, is equal to the whole surface of the dodecahedron. For if lines are drawn from F to all the angles of the pentagon, the pentagon will be resolved into five equal triangles, by the corollary to Proposition 8 of Book 1, since two sides of each are equal to two sides of the others, and the base of each is likewise equal to the bases of the others. Let there also be drawn through F the line HI, parallel to CD, meeting the two perpendiculars CH and DI — drawn from C and D to CD — at the points H and I. Then the rectangle CI will be that contained by HC, that is, by FG and CD. [Margin: a — *Elements* I.41] Now since the rectangle CI is also double the triangle FCD — and so double each of the remaining four triangles equal to FCD — the rectangle CI, taken five times, will be equal to ten such triangles, that is, to two pentagons of the dodecahedron, since five equal triangles make up one pentagon. And therefore six times the rectangle CI taken five times — that is, the rectangle CI taken thirty times — will likewise be equal to six times the two pentagons, that is, to twelve pentagons, that is, to the whole surface of the dodecahedron. If, then, from the center of the circle circumscribing a pentagon of the dodecahedron, and so on. This was to be demonstrated.

Alternatively. With the same construction of the figure made, [Margin: b — *Elements* I.41] since the rectangle CI is double the triangle FCD — that is, equal to the triangle FCD taken twice — the rectangle CI taken thirty times will be equal to the triangle FCD taken twice thirty times, that is, taken sixty times; and hence to the whole surface of the dodecahedron. For since one pentagon of the dodecahedron consists of five such triangles, the twelve pentagons — namely the whole surface of the dodecahedron — will consist of sixty such triangles. And therefore the triangle FCD, taken sixty times, will be equal to the surface of the dodecahedron.

Diagram. A circle with center F, in which the pentagon ABCDE is inscribed: A at the top, B at the upper left, E at the upper right, C at the lower left, D at the lower right. Lines are drawn from F to all five vertices. The perpendicular FG drops from F to the base CD, meeting it at G. Through F the line HI is drawn parallel to CD, meeting the perpendiculars CH (at H, left) and DI (at I, right); the rectangle HC DI (the rectangle CI) is thereby formed.

- A (top): pentagon vertex
- B (upper left), E (upper right): pentagon vertices
- C (lower left), D (lower right): endpoints of the base
- F (center): center of the circle
- G (on CD): foot of the perpendicular FG
- H (left, on HI): corner of the rectangle, foot of perpendicular from C
- I (right, on HI): corner of the rectangle, foot of perpendicular from D

THEOR. 7. PROPOS. 7.

[Margin: outer dual proposition numbers "iij. / vij."]

If, from the center of the circle circumscribing a triangle of the icosahedron, a perpendicular is drawn to one side of the triangle, then the rectangle contained by the said side and the perpendicular, taken thirty times, will be equal to the surface of the icosahedron.

Demonstration. From D, the center of the circle circumscribing the triangle ABC of the icosahedron, let the perpendicular DE be drawn to the side. I say that the rectangle contained by DE and BC, taken thirty times, is equal to the whole surface of the icosahedron. For if lines are drawn from D to all the angles of the triangle, the triangle will be resolved into three equal triangles, by the corollary to Proposition 8 of Book 1; for two sides of each are equal to two sides of the others, and the base of each is equal to the bases of the others.

Proposition 7 — Demonstration (continued)

Let there also be drawn through D the line FG, parallel to BC, meeting at F and G the two perpendiculars BF and CG drawn from B and C to DE. Then the rectangle BG will be that contained by BF, that is, by DE and BC. [Margin: a — *Elements* I.41] Now since the rectangle BG is double the triangle BDC — and so double each of the remaining two triangles equal to BDC — the rectangle BG, taken three times, will be equal to six such triangles, that is, to two triangles of the icosahedron, since three such equal triangles make up one triangle of the icosahedron. And therefore the same rectangle taken thirty times — namely ten times the rectangle BG taken three times — will be equal to twenty triangles of the icosahedron, that is, to the whole surface of the icosahedron, namely to ten times the two triangles of the icosahedron. If, then, from the center of the circle circumscribing a triangle of the icosahedron, and so on. This was to be shown.

Alternatively. With the same construction of the figure made, [Margin: b — *Elements* I.41] since the rectangle BG is double the triangle DBC — that is, equal to the said triangle taken twice — the rectangle BG taken thirty times will be equal to the triangle DBC taken sixty times. But sixty such triangles make up twenty triangles of the icosahedron, since three make one. Therefore the rectangle BG, taken thirty times, is equal to the whole surface of the icosahedron.

Diagram. A circle with center D, in which the equilateral triangle ABC is inscribed: A at the top, B at the lower left, C at the lower right. Lines are drawn from D to the three vertices. The perpendicular DE drops from D to the base BC at E. Through D the line FG is drawn parallel to BC, meeting the perpendiculars BF (at F, left) and CG (at G, right); the rectangle FBCG (the rectangle BG) is thereby formed, with its diagonals drawn.

- A (top): triangle vertex
- B (lower left), C (lower right): endpoints of the base
- D (center): center of the circle
- E (on BC): foot of the perpendicular DE
- F (left, on FG): corner of the rectangle, foot of perpendicular from B
- G (right, on FG): corner of the rectangle, foot of perpendicular from C

Corollary

And so the surface of any dodecahedron is to the surface of any icosahedron whatever — even if the two figures are not described in the same sphere — as the rectangle contained by the side of the dodecahedron and the perpendicular

drawn from the center of the pentagon of the dodecahedron to the said side, is to the rectangle contained by the side of the icosahedron and the perpendicular drawn from the center of the triangle of the icosahedron to its said side. [Margin: c — *Elements* XIV.6] For since the surface of the dodecahedron is equal to the first rectangle taken thirty times, [Margin: d — *Elements* XIV.7] and likewise the surface of the icosahedron is equal to the second rectangle taken thirty times as well, that first rectangle will be a thirtieth part of the surface of the dodecahedron, just as this second rectangle is a thirtieth part of the surface of the icosahedron. [Margin: e — *Elements* V.15] Therefore the surface of the dodecahedron will be to the surface of the icosahedron as that first rectangle — the thirtieth part of the dodecahedron — is to this second rectangle, the thirtieth part of the icosahedron. This is what was proposed.

Scholium

By an argument not unlike this we shall investigate the surfaces of the remaining three regular solids, namely of the tetrahedron, the octahedron, and the cube. For if, from the center of the circle circumscribing the triangle of the tetrahedron, or of the octahedron, or the square of the cube, a perpendicular is drawn to any one of their sides, then the rectangle contained by the said side and the perpendicular will — in the case of the tetrahedron, taken six times — be equal to the surface of the tetrahedron; while in the case of the octahedron and the cube, taken twelve times, it will be equal to the surface of the octahedron and of the cube. For let there be, first, the triangle ABC of the tetrahedron, circumscribed by a circle whose center is D, from which let the perpendicular DE be drawn to the side BC, and let the rest be done as was said of the triangle of the icosahedron. I say that the rectangle BG, taken six times, is equal to the surface of the tetrahedron. [Margin: f — *Elements* I.41] For since the rectangle BG is double the triangle DBC — that is, equal to two such triangles — it, taken six times, will be equal to twelve such triangles. Since, then, twelve such triangles make up the whole surface of the tetrahedron — namely four equilateral triangles equal to ABC, because three make one — the rectangle BG, taken six times, will be equal to the surface of the tetrahedron, or pyramid.

Next let the same triangle ABC be of the octahedron, and so on. I say that the rectangle BG, taken twelve times, is equal to the surface of the octahedron. [Margin: g — *Elements* I.41] For since the rectangle BG is double the triangle DBC — that is, equal to two such triangles — the same rectangle BG, taken twelve times, will be equal to twenty-four such triangles. But twenty-four such triangles make up the eight triangles of the octahedron, that is, the whole surface of the

octahedron, because three make one. Therefore the rectangle BG, taken twelve times, is equal to the surface of the octahedron.

Let there be, thirdly, the square HIKL of the cube, about which a circle is described from the center M; and, MN having been drawn as a perpendicular to IK, let lines be drawn from M to all the angles of the square, so that the square is resolved into four equal triangles. Then through M let OP be drawn parallel to IK. I say that the rectangle IP, contained by OI — that is, by MN — and IK, taken twelve times, is equal to the surface of the cube. [Margin: h — *Elements* I.41] For since the rectangle IP is double the triangle MIK — that is, equal to two such triangles — it, taken twelve times, will be equal to twenty-four such triangles. Therefore, since twenty-four such triangles make up six squares — that is, the whole surface of the cube, because four such triangles make one square — the rectangle IP, taken twelve times, will be equal to the surface of the cube. This is what was proposed.

Alternatively. Since two rectangles IP make up the square HIKL — for IP and PH are equal, since the line OI is half the side HI, being equal to MN — twelve such rectangles will constitute six such squares, that is, the whole surface of the cube.

Diagram. Two circles side by side. **Left circle:** the equilateral triangle ABC inscribed, center D, as in Proposition 7 — A at the top, B at the lower left, C at the lower right; perpendicular DE to the base BC at E; the line FG through D parallel to BC, meeting BF (at F) and CG (at G), forming the rectangle FBCG (the rectangle BG) with its diagonals. **Right circle:** the square HIKL of the cube inscribed, center M — H at the upper left, L at the upper right, I at the lower left, K at the lower right; lines drawn from M to the four corners; MN dropped perpendicular from M to the side IK at N (lower middle); OP drawn through M parallel to IK, meeting the left side at O and the right side at P; the rectangle OIKP (the rectangle IP), the lower half of the square, is thereby formed.

- Left circle — A (top), B (lower left), C (lower right): triangle vertices; D (center); E (foot of perpendicular on BC); F (left), G (right): rectangle corners on FG
- Right circle — H (upper left), L (upper right), I (lower left), K (lower right): square vertices; M (center); N (foot of perpendicular MN on IK); O (left, on OP), P (right, on OP): endpoints of the parallel through the center

PROBL. 8. PROPOS. 8.

[Margin: outer dual proposition numbers "iv. / viij."]

The rectangle contained by three-quarters of the diameter of some circle and by five-sixths of the line subtending the angle of an equilateral pentagon described in the same circle is equal to the said pentagon.

Book XIV (the Hypsicles supplement)

Proposition 8 (demonstration, continued)

In the circle whose center is F, let the equilateral pentagon ABCDE be inscribed, and let the diameter AG be drawn and divided into four equal parts, of which three make up AH. Let the straight line BE, which subtends the angle A, be cut into six equal parts, of which five make up BI and one makes up IE, so that BI is five times IE. I say that the rectangle contained by AH and BI is equal to the pentagon ABCDE.

For let the straight line BF be drawn. Since AH contains three-quarters of the diameter, and AF two-quarters (being the radius), AH will be to AF as three to two. And since the straight line FA, which bisects the arc BAE, also bisects the straight line BE at the point K (by corollary 1 of *Elements* XIII.10), KB and KE will each contain three-sixths of BE; and so, since BI contains five of them, KI will contain two. Consequently KB is to KI also as three to two. Therefore AH is to AF as KB is to KI [Margin: a — *Elements* VI.16]; and hence the rectangle under the extremes AH, KI will be equal to the rectangle under the means AF, KB [Margin: b — *Elements* I.41]. Now the rectangle under AF, KB is double the triangle ABF, since the rectangle and the triangle have the same base AF and the same height BK—that is, they stand between the same parallels. Therefore the rectangle under AH, KI is likewise double the same triangle ABF. But the rectangle under AH, KI is also double the rectangle under AH, IE [Margin: c — *Elements* VI.1], because the base KI is double the base IE (for KI contains two sixths of BE, and IE one), the height AH remaining the same. Therefore the triangle ABF and the rectangle under AH, IE are equal; and so their quintuples are equal as well. But the pentagon ABCDE is five times the triangle ABF, since the pentagon is resolved into five such triangles by drawing straight lines from the center F, as we showed in Proposition 6 of this book. And the rectangle under AH, BI is five times the rectangle under AH, IE [Margin: d — *Elements* VI.1], since the base BI is five times the base IE, the height AH remaining the same. Therefore the pentagon ABCDE and the rectangle under AH, BI are equal. The rectangle, then, contained by the three-quarters [of the diameter and the five-sixths of the subtending line], and so forth. Which was to be demonstrated.

Diagram. A circle with center F and inscribed equilateral pentagon ABCDE. The vertical diameter runs from A (top) down through the interior to G (bottom). The chord BE is horizontal, subtending the pentagon's apex angle at A, and is marked with tick-strokes dividing it into equal parts.

- A (top of circle): apex vertex of the pentagon; upper end of the diameter AG
- B (left, on chord BE): pentagon vertex
- E (right, on chord BE): pentagon vertex
- C (lower left): pentagon vertex
- D (lower right): pentagon vertex
- G (bottom of circle): lower end of the diameter
- K (interior, on the vertical diameter where it meets chord BE): bisection point of BE
- I (on chord BE, right of K): division point marking the segment IE
- F (interior, below K on the vertical line): center of the circle
- H (interior, below F on the vertical line): point dividing the diameter (AH = three-quarters of the diameter)

Corollary

Moreover, if the pentagon ABCDE is set up as the base of a dodecahedron inscribed in some sphere, then BE is the side of the cube inscribed in the same sphere (by corollary 2 of *Elements* XIII.17), and it is likewise one side of the triangle of the icosahedron set up in the same sphere [Margin: e — *Elements* XIV.5]—being, that is, comprehended by the same circle as the pentagon of the dodecahedron. This line cuts the diameter AG at H (since, by the corollary to *Elements* XIII.12, it bisects the semidiameter FG, just as the point H likewise bisects the same semidiameter FG). It is therefore manifest that the rectangle contained by the perpendicular drawn from an angle of the icosahedron's triangle to one of its sides—namely AH—and by five-sixths of the side of the cube belonging to the same sphere in which the icosahedron is inscribed—namely BI—is equal to the pentagon of the dodecahedron set up in the same sphere.

THEOR. 9. PROPOS. 9.

[Margin: iv. / viij.]

The surface of the dodecahedron has to the surface of the icosahedron inscribed in the same sphere the same ratio as the side of the cube to the side of the icosahedron.

In the circle ABCD [Margin: a — *Elements* XIV.5]—which circumscribes both the pentagon of the dodecahedron and the triangle of the icosahedron—let BD be the side of the pentagon and AD the side of the triangle; and from the center E let the perpendiculars EF, EG be drawn to AD and BD; and finally let H be the side of the cube inscribed in the same sphere as the dodecahedron and the icosahedron. I say that as H, the side of the cube, is to AD, the side of the icosahedron, so is the surface of the dodecahedron to the surface of the icosahedron. For since, when the side of the cube H is cut in extreme and mean ratio, the greater segment is BD, the side of the dodecahedron (by corollary 2 of *Elements* XIII.17); and since, when the straight line EG is likewise cut in extreme and mean ratio, the greater segment is EF (by the scholium to Proposition 2 of this book) [Margin: b — *Elements* XIV.2]: as H, the whole, is to BD, its greater segment, so will EG, the whole, be to EF, its greater segment. And accordingly the rectangle under the extremes H, EF will be equal to the rectangle under the means BD, EG [Margin: c — *Elements* VI.16]. Now since, as H is to AD, so is the rectangle under H, EF to the rectangle under AD, EF [Margin: d — *Elements* VI.1] (their bases being H and AD, while the width remains the same, EF): as H is to AD, so also will the rectangle under BD, EG (which is equal to the rectangle under H, EF) be to the same rectangle under AD, EF. Therefore, since by the corollary to Proposition 7 of this book, as the rectangle under BD, EG is to the rectangle under AD, EF, so is the surface of the dodecahedron to the surface of the icosahedron: as H, the side of the cube, is to AD, the side of the icosahedron, so also will the surface of the dodecahedron be to the surface of the icosahedron. Therefore the surface of the dodecahedron is to the surface of the icosahedron, and so forth. Which was to be shown.

Diagram. A circle with center E, in which a pentagon-side and a triangle-side are drawn, with perpendiculars from the center to those sides; the cube-side H is shown separately as a vertical measuring-segment (marked with tick-strokes) to the right of the circle.

- A (left, on the circle): triangle vertex (endpoint of the icosahedron side AD)
- D (right, on the circle): common endpoint of the pentagon side BD and the triangle side AD
- E (interior, upper): center of the circle
- F (interior, below E): foot of the perpendicular EF onto AD
- G (interior, below F): foot of the perpendicular EG onto BD
- B (lower left, on the circle): endpoint of the pentagon side BD
- C (bottom, on the circle): circle point

- H (right of the circle, vertical segment): the side of the cube, drawn as a separate measuring line

Otherwise

[Margin: e — *Elements* XIV.5] Let the same circle, whose center is H, circumscribe the pentagon ABCDE of the dodecahedron and the triangle AFG of the icosahedron. Then let the straight line AI be drawn from A through the center H; by corollary 2 of *Elements* XIII.10 it will bisect the side FG at right angles. Finally let the straight line BE be joined, which will be the side of the cube (by corollary 2 of *Elements* XIII.17); and let BK be five-sixths of it. I say again that as BE, the side of the cube, is to FG, the side of the icosahedron, so is the surface of the dodecahedron to the surface of the icosahedron. For since the rectangle under AI, BK is equal to the pentagon ABCDE (by the corollary to Proposition 8 of this book), and the rectangle under AI, IF is equal to the triangle AFG (by the scholium to *Elements* I.41, since FG, the base of the triangle, is double IF, the base of the rectangle): as the rectangle under AI, BK is to the rectangle under AI,

Diagram. A circle with center H in which the pentagon ABCDE and the triangle AFG are inscribed, with connecting chords forming a pentagram-like figure.

- A (top): common apex of the pentagon and the triangle
- B (upper left): pentagon vertex
- E (upper right): pentagon vertex
- K (interior, near E): intersection point of connecting lines
- H (center): center of the circle
- F (left): triangle vertex
- I (bottom center): midpoint of the triangle base FG (foot of AI)
- G (right): triangle vertex
- C (lower left): pentagon vertex
- D (lower right): pentagon vertex

THEOR. 9. PROPOS. 9. — "Otherwise" (continued)

[Margin: f — *Elements* VI.1] IF, so is the pentagon ABCDE to the triangle AFG. But as the rectangle under AI, BK is to the rectangle under AI, IF, so is BK to IF, since their bases are BK and IF while the height AI remains ever the same. Therefore, as the pentagon ABCDE is to the triangle AFG, so also is BK to IF. And accordingly—if the first and third, namely the pentagon ABCDE and the straight line BK, are equally multiplied by the number 12, and likewise the second and fourth, namely

the triangle AFG and the straight line IF, are equally multiplied by the number 20 [Margin: g — scholium to *Elements* V.22]—then also, as the pentagon ABCDE taken twelve times (that is, the surface of the dodecahedron) is to the triangle AFG taken twenty times (namely, to the surface of the icosahedron), so is the straight line BK taken twelve times to the straight line IF taken twenty times. But BK taken twelve times equals the side of the cube BE taken ten times (for since BK contains five-sixths of BE, BK taken twelve times will contain sixty sixths of BE, which make up ten whole lines BE). And IF taken twenty times equals the side of the icosahedron FG taken ten times (because FG is double IF). Therefore the surface of the dodecahedron will be to the surface of the icosahedron as the side of the cube BE taken ten times is to the side of the icosahedron FG taken ten times. And accordingly, since ten sides of the cube have to ten sides of the icosahedron the same ratio as one side of the cube to one side of the icosahedron [Margin: h — *Elements* V.15], it is clear that the surface of the dodecahedron is to the surface of the icosahedron as the side of the cube to the side of the icosahedron. Which is what was proposed.

Diagram. The figure for the "Otherwise" proof, reproduced: a circle with center H, in which the pentagon ABCDE and the triangle AFG are inscribed with their connecting chords.

- A (top): common apex of the pentagon and the triangle
- B (upper left): pentagon vertex
- E (upper right): pentagon vertex
- K (interior, near E): intersection point of connecting lines
- I (interior, right of center): point on the horizontal line
- F (interior, below K): triangle vertex / midpoint region
- H (center): center of the circle
- C (lower left): pentagon vertex
- D (lower right): pentagon vertex
- G (bottom): triangle vertex

THEOR. 10. PROPOS. 10.

[Margin: iv. / ix.]

If a straight line is cut in extreme and mean ratio, then the line whose square equals the [squares] on the whole and on the greater segment will be to the line whose square equals the [squares] on the whole and on the

lesser segment as the side of the cube to the side of the icosahedron inscribed in the same sphere as the cube.

Let the straight line AB be cut at C in extreme and mean ratio, and let AC be the greater segment. Let D be the side of the cube and E the side of the icosahedron inscribed in the same sphere as the cube. With A as center and radius AB let a circle be described, and in it let the equilateral pentagon BFGHI and the equilateral triangle BKL be constructed. If, then, BF is taken as the side of the dodecahedron of some sphere, the straight line BG, when drawn, will be the side of the cube inscribed in the same sphere (by corollary 2 of *Elements* XIII.17). Now since AC, the greater segment of the semidiameter AB cut in extreme and mean ratio, is the side of the decagon [Margin: a — *Elements* XIV.4] in the circle BFGHI—in which AB is the side of the hexagon—BF will be able to produce, as its square, the [square on the] whole AB (that is, the side of the hexagon) together with the [square on the] greater segment AC (that is, the side of the decagon) in the same circle [Margin: b — *Elements* XIII.10]. And now let the straight line M be able to produce, as its square, the [squares on the] whole AB and the lesser segment BC, by what we demonstrated at *Elements* I.47. I say that the proposed side D of the cube is to the proposed side E of the icosahedron as BF—whose square equals the [squares on the] whole AB and the greater segment AC—is to M—whose square equals the [squares on the] whole AB and the lesser segment BC. For since the square on the side of the equilateral triangle BK [Margin: c — *Elements* XIII.12] is triple the square on the semidiameter AB; and likewise the squares on AB, BC are triple the square on AC [Margin: d — *Elements* XIII.4]: as the square on BK is to the square on AB, so will the squares on AB, BC—that is, the square on M, which is equal to them—be to the square on AC. For in both cases the ratio is triple. Therefore, by permutation, as the square on BK is to the square on M, so is the square on AB to the square on AC. But as the square on AB is to the square on AC, so is the square on BG to the square on BF. (For since BF is the greater segment of BG cut in extreme and mean ratio—by corollary 1 of *Elements* XIII.17, because BG is the side of the cube and BF the side of the dodecahedron of the same sphere—it will follow [Margin: e — *Elements* XIV.2] that, as the whole AB is to its greater segment [AC, so the whole BG is to] its greater segment BF [?]; and accordingly [Margin: f — *Elements* VI.22], as the square on AB is to the square on AC, so is the square on BG to the square on BF.) Therefore, as the square on BG is to the square on BF, so is the square on BK to the square on M; and, by permutation, as the square on BG is to the square on BK, so is the square on BF to the square on M. And on this account [Margin: g — *Elements* VI.22], as the straight line BG is to the straight line BK, so is BF—whose square equals the [squares on the] whole AB and the greater segment AC—to M—whose square equals the

[squares on the] whole AB and the lesser segment BC. Since, then, the proposed sides D, E of the cube and icosahedron have the same ratio as the straight lines BG, BK (as we shall show shortly), it is clear that, as the straight line BF (whose square equals the whole AB and the greater segment AC) is to the straight line M (whose square equals the whole AB and the lesser segment BC), so also the proposed side D of the cube is to the proposed side E of the icosahedron. If, therefore, a straight line is cut in extreme and mean ratio, and so forth. Which was to be shown.

Diagram. A circle with center A, in which an equilateral pentagon BFGHI and an equilateral triangle BKL are inscribed; below the circle three separate measuring-segments are drawn, labelled D and E (bracketed together) and M.

- B (top, on the circle): common vertex of the pentagon and the triangle
- F (upper left): pentagon vertex
- I (upper right): pentagon vertex
- C (interior, mid-left): division point on the diameter (segment AC)
- A (center): center of the circle
- L (interior, mid-right): triangle vertex region
- K (lower left, on the circle): triangle vertex
- G (bottom, on the circle): pentagon vertex
- H (lower right, on the circle): pentagon vertex
- D, E (segments below the circle, bracketed together): the side of the cube (D) and the side of the icosahedron (E)
- M (segment below the circle): the constructed line whose square equals the squares on AB and BC

SCHOLIUM

That the proposed sides D and E of the cube and icosahedron of the same sphere have the same ratio as the straight lines BG, BK, we shall demonstrate by the following theorem.

The ratio that the sides of the cube and the icosahedron of the same sphere have, the sides of the cube and the icosahedron described in any other sphere also have.

For let A be the side of the cube and BC the side of the icosahedron of the same sphere; and let D be the side of the cube and EF the side of the icosahedron in any other sphere. I say that as A is to BC, so is D to EF. For when the triangles of the

icosahedra, BCG and EFH, have been completed, and circles have been described about them, let there be inscribed in these circles the equilateral pentagons BIKLM, ENOPQ; and let the straight lines BK,

SCHOLIUM (continued)

CK, EO, FO be joined. [Margin: h — Elements XIV.5] Since, then, the same circle comprehends both the pentagon of the dodecahedron and the triangle of the icosahedron of the same sphere; and since BCG is taken as the triangle of the icosahedron described in the same sphere in which the cube of side A [is inscribed]: BIKLM will be the pentagon of the dodecahedron described in the same sphere as they are. And therefore, by corollary 2 of Elements XIII.17, the straight line BK will be the side of the cube of the same sphere, and hence equal to A itself. By a similar argument the straight line EO will be equal to D, the side of the cube. Again, since the arcs BIK, ENO are similar (for each contains two-fifths of its own circumference), and likewise the arcs BGC, EHF (for each comprehends two-thirds of the whole circumference): the angles BCK, EFO will be equal to one another, by the definition of similar segments, as will the angles BKC, EOF to one another, since both the former and the latter stand in similar segments of circles. And accordingly, by corollary 1 of Elements I.32, the remaining angle CBK of the triangle BCK will be equal to the remaining angle FEO of the triangle EFO, and the whole triangle BCK will be equiangular with the whole triangle EFO. [Margin: i — Elements VI.4] Therefore, as BK—that is, the straight line A equal to it, namely the side of the cube—is to BC, the side of the icosahedron, so is EO—that is, the straight line D equal to it, namely the side of the other cube—to EF, the side of the icosahedron. Which is what was proposed.

It is therefore clear what was assumed in the demonstration, namely that D and E, the sides of the cube and icosahedron in one sphere, have the same ratio as BG, BK, the sides of the cube and icosahedron in another sphere.

From this it is also inferred that the surface of the dodecahedron has to the surface of the icosahedron not only the same ratio as the side of the cube to the side of the icosahedron in the same sphere as they are (as Proposition 9 of this book maintains), but also the ratio that the side of the cube has to the side of the icosahedron in any other sphere whatever.

Diagram. Two circles side by side. In each, an icosahedron triangle and an inscribed equilateral pentagon are drawn, with connecting chords; beneath each circle a measuring-segment gives the side of the cube of that sphere.

Left circle (triangle BCG, pentagon BIKLM):

- B (top): common vertex of triangle and pentagon
- I (left): pentagon vertex
- C (lower left): triangle vertex
- G (lower right): triangle vertex
- M (right): pentagon vertex
- K (bottom left): pentagon vertex
- L (bottom right): pentagon vertex
- A (segment beneath the circle): the side of the cube of this sphere

Right circle (triangle EFH, pentagon ENOPQ):

- E (top): common vertex of triangle and pentagon
- N (left): pentagon vertex
- F (lower left): triangle vertex
- H (lower right): triangle vertex
- Q (right): pentagon vertex
- O (bottom left): pentagon vertex
- P (bottom right): pentagon vertex
- D (segment beneath the circle): the side of the cube of this sphere

LEMMA I

If a sphere is cut by any plane, the common section will be a circle.

Let the sphere ABC, whose center is D, be cut by some plane producing the plane common section BEFCG. I say that BEFCG is a circle. First, let the cutting plane pass through the center of the sphere, so that the center D lies in the plane—that is, in the common section BEFCG; and from D, the center of the sphere, let any number of straight lines DE, DF, DG be drawn to the boundary of the common section. Since, then, all these lines that have been drawn, however many there be, are equal—by the definition of the sphere, since they fall from its center to its surface—the plane figure BEFCG, contained by a single line, will (by the definition of a circle) be a circle, and its center D will be the same as the center of the sphere.

Secondly, let the cutting plane not pass through the center of the sphere. From D, the center of the sphere, let the perpendicular DH be dropped to the cutting plane; and from H let straight lines HE, HF be drawn anywhere, as far as the boundary of the common section; and let the straight lines DE, DF be joined. Since, then, the angles DHE, DHF are right angles (by definition 3 of Book XI), [Margin: k —

Elements I.47] the square on DE will be equal to the squares on DH, HE, and the square on DF equal to the squares on DH, HF. But the squares on DE, DF—which are equal, falling from the center of the sphere to its surface—are equal. Therefore the squares on DH, HE will also be equal to the squares on DH, HF; and accordingly, when the common square on DH is taken away, the remaining square on HE will be equal to the remaining square on HF. Hence HE and HF will also be equal. By the same argument we shall show that all lines falling from H to the boundary of the common section are equal both to one another and to the two named lines HE, HF. Therefore the plane figure BEFCG, contained by a single line, will (by the definition of a circle) be a circle; and its center is the point H, upon which the perpendicular DH falls. Which is what was proposed.

Diagram. Two shaded globe (sphere) figures illustrating the two cases. In the left globe the cutting plane passes through the center; in the right globe it does not, and the perpendicular from the center to the cutting plane is drawn.

Left globe (plane through the center):

- A (top): pole/point of the sphere
- G (upper left, on the section): boundary point of the common section
- B (left): boundary point
- D (center): center of the sphere and of the section-circle
- C (right): boundary point
- E (lower left, on the section): boundary point
- F (lower center, on the section): boundary point

Right globe (plane not through the center):

- A (top): pole/point of the sphere
- B (left): boundary point of the common section
- D (interior, upper): center of the sphere
- G (interior, just below D): point on the perpendicular / section
- C (right): boundary point
- E (lower left, on the section): boundary point (endpoint of HE)
- H (bottom center): foot of the perpendicular DH, center of the section-circle
- F (bottom, right of H, on the section): boundary point (endpoint of HF)

COROLLARY

Therefore, if the cutting plane passes through the center of the sphere, the circle produced will have the same center as the sphere. But if the cutting plane does

not pass through the center of the sphere, the circle produced will have a center different from the sphere's—namely, that point upon which the perpendicular drawn from the center of the sphere to the cutting plane falls. For it can always be demonstrated that the straight lines falling from this point to the circumference of the circle are equal, as is clear.

LEMMA II

Equal circles in a sphere are equally distant from the center of the sphere; and circles equally distant from the center of the sphere are equal.

In the sphere ABCD, whose center is E, let there be equal circles AB, DC. I say that they are equally distant from the center E. For let the perpendiculars EF, EG be drawn from E to their planes; which, by the corollary of the preceding lemma,

Euclid's *Elements*, Book XIV (the Hypsicles supplement) — continued

Lemma II (concluded)

(Continuing the proof that equal circles in a sphere are equally distant from the center. Sphere ABCD, center E; equal circles AB, DC; perpendiculars EF, EG.)

of the lemma, will fall on the centers of those circles. From these centers draw the lines FB, GC to the circumferences of the circles at any points you like, and join the lines EB, EC. Now since the angles EFB and EGC are right angles, by definition 3 of Book XI, [Margin: l 47.pri. (Elements I.47)] the square on EB will equal the squares on EF and FB together, and likewise the square on EC will equal the squares on EG and GC together. But the squares on the equal lines EB and EC are themselves equal, since these lines fall from the center of the sphere to its surface. Therefore the squares on EF and FB together equal the squares on EG and GC together. And so, when the equal squares on the equal lines FB and GC are taken away — for these are the radii of equal circles — the remaining square on EF equals the remaining square on EG. The perpendiculars EF and EG are therefore equal. For this reason the circles AB and DC are equally distant from the center E.

Diagram. A circle representing the sphere, with center E, and two lens-shaped chord-figures (the two circles seen nearly edge-on) drawn inside it toward the left and right.

- A (upper left of the sphere): endpoint of the left circle
- D (upper right of the sphere): endpoint of the right circle
- B (lower left): endpoint of the left circle
- C (lower right): endpoint of the right circle
- E (center of the sphere): the center from which the perpendiculars are drawn
- F (left of center): foot of the perpendicular EF on the plane of circle AB
- G (right of center): foot of the perpendicular EG on the plane of circle DC

Conversely, let the circles AB and DC now be equally distant from the center E of the sphere. I say that they are equal. For, once the figure has been constructed as before, we shall show in the same way that the squares on EF and FB together equal the squares on EG and GC together. And so, when the equal squares on the equal lines EF and EG are taken away — the circles being assumed equally distant from the center — the remaining square on FB equals the remaining square on GC; hence the lines FB and GC are equal, that is, the radii of the circles AB and DC. Therefore the circles AB and DC are equal. This is what was proposed.

THEOR. 11. PROPOS. 11.

[Margin: iv. / x. (Hypsicles / Campanus proposition numbers)]

The dodecahedron is to the icosahedron described in the same sphere with it as the edge of the cube is to the edge of the icosahedron — in one and the same sphere.

Let a dodecahedron, one of whose pentagons is FGHK, be inscribed in the sphere ABCD, whose center is E; likewise an icosahedron, one of whose triangles is LMN. I say that the dodecahedron is to the icosahedron as the edge of the cube is to the edge of the icosahedron, in one and the same sphere — whether this sphere be the same as sphere ABCD or not. Since all the vertices, both of the pentagon and of the triangle, touch the surface of the sphere, then if planes are passed through the pentagon and through the triangle, there will be produced, by the preceding Lemma 1, two circles in the sphere, FGHK and LMN, containing the pentagon and the triangle respectively.

[Margin: a 5.quartidec. (Elements XIV.5)] Since one and the same circle contains both the pentagon of the dodecahedron and the triangle of the icosahedron, the circles FGHK and LMN will therefore be equal; and consequently, by the preceding Lemma 2, they will be equally distant from the center E of the sphere. Hence the perpendiculars drawn from E to the planes of the circles, and falling — by the corollary of Lemma 1 — on their centers O and P, will be equal, namely EO and EP. In just the same way it will be shown that the perpendiculars drawn from E to all the pentagons of the dodecahedron, and to all the triangles of the icosahedron, are equal. Therefore, if straight lines are drawn from all the vertices of the dodecahedron to E, the dodecahedron will be resolved into twelve pyramids of equal height; and since their bases too are equal — namely the pentagons of the dodecahedron — the pyramids will be equal to one another, by the corollary of Proposition 6 of Book XII. In the same way, if straight lines are drawn from all the vertices of the icosahedron to E, the icosahedron will be resolved into 20 pyramids equal to one another, whose heights will equal the heights of the pyramids of the dodecahedron.

[Margin: b 6.duodecim. (Elements XII.6)] Now since the base FGHK is to the base LMN as the pyramid FGHKE is to the pyramid LMNE — for the two have the same height — then also, by what we demonstrated in the scholium to Proposition 22 of Book V, as the twelve bases of the dodecahedron, that is, the whole surface of the dodecahedron, is to the base LMN, so are the twelve pyramids of the dodecahedron, that is, the whole solid of the dodecahedron, to the pyramid LMNE. Again, since (as we have just said) the whole surface of the dodecahedron is to the icosahedron's base LMN as the dodecahedron is to the pyramid LMNE, it will follow, by the same scholium, that as the whole surface of the dodecahedron is to the 20 bases of the icosahedron — that is, to the whole surface of the icosahedron — so is the dodecahedron to the 20 pyramids of the icosahedron, namely to the whole solid of the icosahedron.

[Margin: c 9.quartidec. (Elements XIV.9)] And thus the surface of the dodecahedron is to the surface of the icosahedron as the edge of the cube is to the edge of the icosahedron inscribed in the same sphere with them; and moreover, by the scholium to Proposition 10 of this book, as the edge of the cube is to the edge of the icosahedron of any single other sphere. Therefore the dodecahedron will also be to the icosahedron as the edge of the cube is to the edge of the icosahedron of any sphere. And so the dodecahedron is to the icosahedron, and so forth. Which was to be demonstrated.

Diagram. A spherical dome ABCD (center E) above two circles: a left circle containing the dodecahedron's pentagon FGHIK (center O) and a right circle containing the icosahedron's triangle LMN (center P).

- A (top of the dome): vertex of the sphere
- B (upper left of the dome): vertex of the sphere
- D (upper right of the dome): vertex of the sphere
- C (bottom, between the two circles): vertex of the sphere
- E (near the top, between the circles): center of the sphere
- F (top of left circle): vertex of the pentagon
- G (left of left circle): vertex of the pentagon
- H (lower left of left circle): vertex of the pentagon
- I (lower right of left circle): vertex of the pentagon
- K (right of left circle): vertex of the pentagon
- O (center of left circle): center of the circle circumscribing the pentagon
- L (top of right circle): vertex of the triangle
- M (lower left of right circle): vertex of the triangle
- N (lower right of right circle): vertex of the triangle
- P (center of right circle): center of the circle circumscribing the triangle

COROLLARIVM.

[Margin: d 9.quartidec. (Elements XIV.9); e 10.quartidec. (Elements XIV.10); f 11.quartidec. (Elements XIV.11)] Since it has also been shown [d] that the surface of the dodecahedron is to the surface of the icosahedron of the same sphere as the edge of the cube is to the edge of the icosahedron inscribed in the same sphere with them; [e] likewise that the edge of the cube is to the edge of the icosahedron of one and the same sphere as the line whose square equals the whole line cut in extreme and mean ratio together with its greater segment is to the line whose square equals that same whole line together with its lesser segment; [f] likewise that the dodecahedron is to the icosahedron of the same sphere as the edge of the cube is to the edge of the icosahedron in one and the same sphere — it is clear that these four ratios, namely: the edge of the cube to the edge of the icosahedron; the surface of the dodecahedron to the surface of the icosahedron; the line whose square equals any whole line cut in extreme and mean ratio together with its greater segment, to the line whose square equals the same whole line together with its lesser segment; and the dodecahedron to the icosahedron of the same sphere — are all equal to one another.

THEOR. 12. PROPOS. 12.

[Margin: o. / xj.]

The side of an equilateral triangle is, in square, one and a third times (in the ratio 4 : 3) the perpendicular drawn from one angle to the opposite side.

In the equilateral triangle ABC let the perpendicular AD be drawn from the angle A to the opposite side BC. I say that the square on the side AB is one and a third times the square on the perpendicular AD. Since, on account of the equality of the sides AB and AC, [Margin: a 5.pri. (Elements I.5)] the angles B and C are equal, and the angles at D are right angles, the two angles B and D of triangle ADB equal the two angles C and D of triangle ADC; and moreover they have the side AD in common, and AB, AC equal. [Margin: b 6.pri. (Elements I.6)] Therefore the remaining sides BD and CD are also equal; and consequently the side BC — that is, the side AB — is double the line BD, and therefore the square on the side AB is quadruple the square on the line BD, by the scholium to Proposition 4 of Book II. [Margin: c 47.pri. (Elements I.47)] Since, then, the squares on the lines AD and BD together equal the square on AB, the squares on AD and BD together will also be quadruple the square on BD. And so, of whatever parts the square on AB (or the squares on AD and BD together) is 4, of such parts the square on AD will be 1 [i.e. the squares on AD and BD are as 4 : 1, whence the square on BD is 1 part and the square on AD is 3 parts]. Therefore the square on AB, of 4 parts, is one and a third times the square on AD, of 3 parts. Hence the side of an equilateral triangle is, in square, one and a third times [the perpendicular], and so forth. Which was to be shown.

Diagram. An equilateral triangle with apex A and base BC, with the perpendicular AD dropped from A to the base.

- A (apex): the angle from which the perpendicular is drawn
- B (lower left): base vertex
- D (foot of the perpendicular, midpoint of the base): where AD meets BC
- C (lower right): base vertex

COROLLARIVM.

From this it is clear that the perpendicular dropped from one angle of an equilateral triangle to the opposite side bisects both the angle and the side. For it was demonstrated that the lines BD and CD are equal — that is, that the side BC is bisected by the perpendicular AD. Hence, since the sides AB and AD of triangle

ABD equal the sides AC and AD of triangle ACD, and the base BD equals the base CD, [Margin: d 8.pri. (Elements I.8)] the angles BAD and CAD will also be equal; that is, the angle BAC will be bisected by the same perpendicular AD.

THEOR. 13. PROPOS. 13.

[Margin: o. / xiiij.]

If the diameter of a sphere is rational, then the surface both of the tetrahedron and of the octahedron in that sphere is a medial area.

Let A be the rational diameter of a sphere. I say that the surface both of the tetrahedron and of the octahedron in the said sphere is a medial area. For let BCD be one triangle of the tetrahedron, and EFG one triangle of the octahedron of that sphere; and from the angles B and E let the perpendiculars BH and EI be drawn to the opposite sides CD and FG. [Margin: a 13.tertijdec. (Elements XIII.13)] Now since the square on the diameter A is one and a half times the square on the tetrahedron's edge BC, [Margin: b 14.tertijdec. (Elements XIII.14)] and double the square on the octahedron's edge EF, the squares on the lines A, BC, EF will have the ratio of the numbers 6, 4, 3; [Margin: c 6.dec. (Elements X.6)] and therefore they are commensurable. Hence the lines A, BC, EF themselves are commensurable at least in square; and moreover, since A is assumed rational, BC and EF will also be rational, and therefore so too will their halves CH and FI.

[Margin: d 12.quartidec. (Elements XIV.12)] Again, since the square on the line BC is one and a third times the square on BH, and likewise the square on EF one and a third times the square on EI, the squares on BC and BH, and likewise the squares on EF and EI, will have to one another the ratio of the numbers 4, 3; [Margin: e 6.dec. (Elements X.6)] and therefore both pairs are commensurable with one another. Hence the lines BC and BH, and likewise the lines EF and EI, are commensurable. But CH is commensurable with BC, and FI with EF — being their halves, that is, commensurable with the whole. [Margin: f 12.dec. (Elements X.12)] Therefore BH and CH, and likewise EI and FI, are commensurable with one another; and consequently, since CH and FI have been shown rational, BH and EI will also be rational. [Margin: g 9.dec. (Elements X.9)] But since CH and BH, and likewise FI and EI, are incommensurable in length — because their squares do not have the ratio of a square number to a square number (as is clear from the corollary of Proposition 24 of Book VIII, for they have the ratio of 1 to 3, [Margin: h 12.quartidec. (Elements XIV.12)] since it has been shown that of whatever parts the square on CH, or the square on FI, is 1, of such parts the square on BH, or the square on EI, is 3) — [Margin: i 22.dec. (Elements X.22)] CH and BH, and likewise

FI and EI, will be rational commensurable in square only. And consequently the rectangle contained by CH and BH — rational and commensurable in square only — and the rectangle contained by FI and EI — likewise rational and commensurable in square only — will each be a medial area. But the triangles BCD and EFG are equal to the rectangles under CH, BH and under FI, EI respectively, by the scholium to Proposition 41 of Book I, since the bases CD and FG of the triangles are double the bases CH and FI of the rectangles. Therefore the triangles BCD and EFG will also be medial areas. And so, since the whole surface of the tetrahedron is commensurable with the triangle BCD (for the triangle BCD is a quarter of the whole surface), and likewise the whole surface of the octahedron is commensurable with the triangle EFG (for the triangle EFG is an eighth of the whole surface), the surfaces of the tetrahedron and of the octahedron will also, by the corollary of Proposition 24 of Book X, be medial areas. Therefore, if the diameter of a sphere is rational, the surface both of the tetrahedron and of the octahedron in that sphere is a medial area. Which was to be shown.

Diagram. At the top, a straight segment A (the sphere's diameter, marked off with ticks). Below it, two triangles: the tetrahedron's face BCD (apex B, with perpendicular BH to the base) and the octahedron's face EFG (apex E, with perpendicular EI to the base).

- A (top segment): the diameter of the sphere
- B (apex of left triangle): angle of the tetrahedron's face
- C (lower left of left triangle): base vertex
- H (foot of perpendicular on left base): where BH meets CD
- D (lower right of left triangle): base vertex
- E (apex of right triangle): angle of the octahedron's face
- F (lower left of right triangle): base vertex
- I (foot of perpendicular on right base): where EI meets FG
- G (lower right of right triangle): base vertex

COROLLARIVM.

It follows from the demonstration of this proposition that every equilateral triangle whose side is rational is a medial area. For from the fact that the sides BC and EF, and hence their halves CH and FI, were shown to be rational, it was demonstrated that CH and BH, and likewise FI and EI, are rational commensurable in square only; and therefore the rectangles under CH, BH and under FI, EI — that is, the triangles BCD and EFG, which are equal to them — are

medial areas. Since, then, the same reasoning holds for every equilateral triangle whose one side is rational, what is inferred is clear.

THEOR. 14. PROPOS. 14.

[Margin: o. / xiv.]

If a tetrahedron and an octahedron are inscribed in the same sphere, the base of the tetrahedron will be one and a third times ($4 : 3$) the base of the octahedron; but the surface of the octahedron will be one and a half times ($3 : 2$) the surface of the tetrahedron.

Let A be the diameter of a sphere in which are described a tetrahedron, whose base is the triangle BCD, and an octahedron, whose base is the triangle EFG. I say that the triangle BCD is one and a third times the triangle EFG, but that the surface of the octahedron is one and a half times the surface of the tetrahedron. [Margin: a 13.tertijdec. (Elements XIII.13)] For since the square on the diameter A is one and a half times the square on the tetrahedron's edge CD, [Margin: b 14.tertijdec. (Elements XIII.14)] and double the square on the octahedron's edge FG, it follows that of whatever parts the square on the diameter A is 6, of such parts the square on the edge CD is 4, and the square on the edge FG is 3. Therefore the square on the line CD is one and a third times the square on the line FG. But as the square on CD is to the square on FG, so is the triangle BCD to the triangle EFG, [Margin: c 20.& 19.sex. (Elements VI.20 & VI.19)] since both the squares and the triangles have to one another the doubled ratio of the sides CD and FG, being similar. Therefore the triangle BCD is also one and a third times the triangle EFG.

Again, since it has been shown that the triangle BCD is one and a third times the triangle EFG, and hence that of whatever parts the triangle BCD is 4, of such parts the triangle EFG is 3, it follows that the triangle EFG taken eight times — that is, the whole surface of the octahedron — is 24 of those same parts, while the triangle BCD taken four times — that is, the whole surface of the tetrahedron — is 16 of those same parts. For this reason the surface of the octahedron is one and a half times the surface of the tetrahedron of the same sphere. Therefore, if a tetrahedron and an octahedron are inscribed in the same sphere, and so forth. Which was to be shown.

Diagram. At the top, a horizontal segment A (the sphere's diameter). Below it, two triangles: the tetrahedron's base BCD (apex B) at the left and the octahedron's base EFG (apex E) at the right.

- A (top segment): the diameter of the sphere
- B (apex of left triangle): angle of the tetrahedron's base
- C (lower left of left triangle): base vertex
- D (lower right of left triangle): base vertex
- E (apex of right triangle): angle of the octahedron's base
- F (lower left of right triangle): base vertex
- G (lower right of right triangle): base vertex

THEOR. 15. PROPOS. 15.

[Margin: o. / xv.]

A straight line drawn from any angle of a tetrahedron described in a sphere, passing through the center of the sphere, falls on the center of the opposite base and is perpendicular to that base.

Let ABCD be a tetrahedron, contained by four equilateral and equal triangles ABC, DAB, DBC, DCA, in a sphere whose center is E; and from the angle D, through E the center of the sphere, let the straight line DEF be drawn, meeting the base ABC — inscribed in a circle — at the point F. I say that F is the center of the base ABC, and that DF is perpendicular to that base. For draw from E and from F to the angles of the said base the straight lines EA, EB, EC and FA, FB, FC. Since the lines EA, EB, EC, drawn from the center of the sphere to its surface, are equal, the two sides EA, ED of triangle EAD equal the two sides EC, ED of triangle CED; and the bases AD, CD are also equal, being sides of equal equilateral triangles. [Margin: a 8.pri. (Elements I.8)] Therefore the angles AED and CED will be equal; and consequently the remaining angles AEF and CEF will also be equal, [Margin: b 13.pri. (Elements I.13)] because both AED with AEF, and CED with CEF, are equivalent to two right angles. By the same reasoning the angles BEF and CEF will be equal, if the triangles BED and CED are considered. Since, then, the sides EA, EF of triangle EAF equal the sides EC, EF of triangle ECF, and the angles contained by them have been shown equal, [Margin: c 4.pri. (Elements I.4)] the bases FA and FC will be equal. In the same way FB and FC will be equal, if the triangles EBF and ECF are considered. Hence, since the three lines FA, FB, FC falling from F onto the circumference of the circle are equal, [Margin: d 9.ter. (Elements III.9)] F will be the center of the base ABC, that is, of the circle circumscribing it.

And since, by the corollary of Lemma 1 of Proposition 10 of this book, the perpendicular dropped from E, the center of the sphere, to the plane of the circle ABC falls on the center of the circle, it follows that the line DE, drawn through the

center and falling on the center F of the circle, is perpendicular to the plane of the circle, that is, to the base ABC of the tetrahedron. For if another perpendicular were drawn, it would fall on the center of the circle, by the said corollary. Hence, since F has also been demonstrated to be the center of that same circle, one and the same circle would have two centers — which is absurd. Therefore a straight line from any angle, and so forth. Which was to be demonstrated.

Diagram. A tetrahedron ABCD inscribed in a circle (the sphere), with E the center of the sphere and F the center of the base ABC. The lines EA, EB, EC, ED and FA, FB, FC are drawn, together with the axis DEF.

- A (upper left, on the circle): vertex of the tetrahedron
- D (upper right, on the circle): vertex of the tetrahedron (top of the axis DEF)
- B (lower left, on the circle): vertex of the tetrahedron
- C (lower right, on the circle): vertex of the tetrahedron
- E (near center): center of the sphere
- F (below E): center of the base ABC (foot of the axis DEF)

THEOR. 16. PROPOS. 16.

[Margin: o. / xvj.]

An octahedron described in a sphere is divided into two equal and similar pyramids of equal height; and the base of each is a square equal to half the square on the diameter of the sphere.

Let ABCDEF be an octahedron, contained by eight equilateral and equal triangles EAD, EAB, EBC, ECD, FBC, FBA, FAD, FDC, and described in a sphere whose center is G. I say that it is divided into two equal and similar pyramids of equal height, whose common base is a square equal to half the square on the diameter of the sphere. For draw from G, the center of the sphere, to all the angles the straight lines GA, GB, GC, GD, GE, GF, which are equal...

(The demonstration of Proposition 16 begins here and continues on the following page.)

Book XIV

Proposition 16 (continued) — demonstration

for they are semidiameters of the sphere, drawn, that is, from the center to the surface of the sphere. Now the square on the sphere's diameter is double the

square on the octahedron's edge AB, and quadruple the square on the semidiameter AG (from the scholium to *Elements* II.4) [Margin: (a) XIII.14]. So if the square on the sphere's diameter is set at 4 such parts, the square on the line AB will be 2 of those parts and the square on the line AG will be 1; and therefore the square on AB is double the square on AG. Since, then, the square on AG is equal to the square on BG, the square on AB will be equal to the two squares on AG and BG together; and therefore the angle AGB is a right angle [Margin: (b) I.48]. In the same way the remaining angles AGD, BGC, and CGD are shown to be right angles [Margin: (c) I.14]. For this reason AG together with CG, and BG together with DG, will lie in a straight line [Margin: (d) XI.2]; and consequently the lines AC and BD, cutting each other at G, will lie in one plane [Margin: (e) XI.7]; and therefore the lines that join their extremities — AB, BC, CD, DA — lie in the same plane with them. So the quadrilateral ABCD lies in one plane.

The octahedron, then, has been divided into two pyramids ABCDE and ABCDF, whose common base is ABCD and whose apexes are E and F. These pyramids are equal and similar (by *Elements* XI, def. 10), since each is made up of four equilateral triangles of the octahedron, which are equal and similar, together with the common base ABCD.

I now say that their heights are equal, and that the base ABCD is a square equal to half the square on the sphere's diameter. For it has been shown that the square on the octahedron's edge AB is equal to the two squares on the semidiameters AG and BG; likewise the square on the edge AE is equal to the two squares on the semidiameters AG and EG; and therefore the angle AGE is a right angle [Margin: (f) I.48]. By the same reasoning the angle DGE is a right angle. Since, then, the line EG stands at right angles to the two lines AG and DG that cut each other at G, EG itself is perpendicular to the plane ABCD drawn through the lines AG and DG — that is, to the base of the pyramids [Margin: (g) XI.4]. So EG is the height of the pyramid ABCDE. In the same way we shall show that FG is the height of the pyramid ABCDF. Since, then, EG and FG are equal semidiameters of the sphere, it is clear that the said pyramids are of equal height.
